Platonic solids generate their four-dimensional analogues – a 3D spinorial view of 4D exceptional phenomena

Pierre-Philippe Dechant

Mathematics Department, University of York

Birkbeck - November 10, 2014

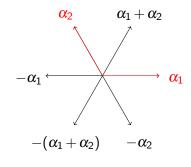

#### Overview

- Introduction
  - Coxeter groups and root systems
  - Clifford algebras
  - 'Platonic' Solids

- 2 Combining Coxeter and Clifford
  - The Induction Theorem from 3D to 4D
  - Automorphism Groups
  - Trinities and McKay correspondence

#### Root systems – $A_2$

Root system  $\Phi$ : set of vectors  $\alpha$  such that 1.  $\Phi \cap \mathbb{R}\alpha = \{-\alpha, \alpha\} \ \forall \ \alpha \in \Phi$ 

$$1. \boxed{\Phi \cap \mathbb{K}\alpha = \{-\alpha, \alpha\} \ \forall \ \alpha \in \Phi}$$

2. 
$$s_{\alpha}\Phi = \Phi \ \forall \ \alpha \in \Phi$$

Simple roots: express every element of  $\Phi$  via a Z-linear combination (with coefficients of the same sign).

#### Coxeter groups

A Coxeter group is a group generated by some involutive generators  $s_i, s_j \in S$  subject to relations of the form  $(s_i s_j)^{m_{ij}} = 1$  with  $m_{ij} = m_{ji} \ge 2$  for  $i \ne j$ .

#### Coxeter groups

A Coxeter group is a group generated by some involutive generators  $s_i, s_j \in S$  subject to relations of the form  $(s_i s_j)^{m_{ij}} = 1$  with  $m_{ii} = m_{ii} \ge 2$  for  $i \ne j$ .

The finite Coxeter groups have a geometric representation where the involutions are realised as reflections at hyperplanes through the origin in a Euclidean vector space  $\mathscr E$ . In particular, let  $(\cdot|\cdot)$  denote the inner product in  $\mathscr E$ , and v,  $\alpha \in \mathscr E$ .

The generator  $s_{\alpha}$  corresponds to the reflection

$$s_{\alpha}: v \rightarrow s_{\alpha}(v) = v - 2 \frac{(v|\alpha)}{(\alpha|\alpha)} \alpha$$

at a hyperplane perpendicular to the root vector  $\alpha$ .

The action of the Coxeter group is to permute these root vectors.

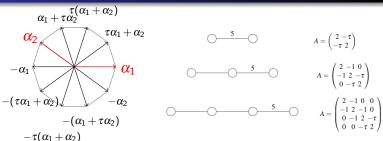

#### Cartan Matrices

Cartan matrix of 
$$\alpha_i$$
s is 
$$A_{ij} = 2\frac{(\alpha_i, \alpha_j)}{(\alpha_i, \alpha_i)} = 2\frac{|\alpha_j|}{|\alpha_i|}\cos\theta_{ij}$$
$$A_2: A = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}$$

Coxeter-Dynkin diagrams: node = simple root, no link = roots orthogonal, simple link = roots at  $\frac{\pi}{3}$ , link with label  $m = \text{angle } \frac{\pi}{m}$ .

$$A_3 \circ - \circ - \circ \qquad B_3 \circ - \circ - \circ \qquad H_3 \circ - \circ - \circ \qquad I_2(n) \circ - \circ$$

# Non-crystallographic Coxeter groups $H_2 \subset H_3 \subset H_4$

 $H_2 \subset H_3 \subset H_4$ : 10, 120, 14,400 elements, the only Coxeter groups that generate rotational symmetries of order 5 linear combinations now in the extended integer ring

$$oxed{\mathbb{Z}[ au] = \{a + au b | a, b \in \mathbb{Z}\}} ext{ golden ratio } oxed{ au = rac{1}{2}(1 + \sqrt{5}) = 2\cosrac{\pi}{5}}$$

$$x^2 = x + 1$$
  $\tau' = \sigma = \frac{1}{2}(1 - \sqrt{5}) = 2\cos\frac{2\pi}{5}$   $\tau + \sigma = 1, \tau\sigma = -1$ 

### Basics of Clifford Algebra I

- Form an algebra using the Geometric Product  $ab \equiv a \cdot b + a \wedge b$  for two vectors
- Extend via linearity and associativity to higher grade elements (multivectors)
- For an *n*-dimensional space generated by n orthogonal unit vectors  $e_i$  have  $2^n$  elements
- Then  $e_i e_j = e_i \wedge e_j = -e_j e_i$  so anticommute (Grassmann variables, exterior algebra)
- Unlike the inner and outer products separately, this product is invertible

### Basics of Clifford Algebra II

- These are known to have matrix representations over the normed division algebras  $\mathbb{R}$ ,  $\mathbb{C}$  and  $\mathbb{H}$   $\Rightarrow$  Classification of Clifford algebras
- E.g. Pauli algebra in 3D (likewise for Dirac algebra in 4D) is

$$\underbrace{\{1\}}_{\text{1 scalar}} \quad \underbrace{\{e_1, e_2, e_3\}}_{\text{3 vectors}} \quad \underbrace{\{e_1 e_2, e_2 e_3, e_3 e_1\}}_{\text{3 bivectors}} \quad \underbrace{\{\textit{I} \equiv e_1 e_2 e_3\}}_{\text{1 trivector}}$$

- These have the well-known matrix representations in terms of σ- and γ-matrices
- Working with these is not necessarily the most insightful thing to do, so here stress approach to work directly with the algebra

#### Reflections

- Clifford algebra is very efficient at performing reflections
- Consider reflecting the vector  $a = a_{\perp} + a_{\parallel}$  in a hypersurface with unit normal n:

$$a' = a_{\perp} - a_{\parallel} = a - 2a_{\parallel} = a - 2(a \cdot n)n$$

- c.f. fundamental Weyl reflection  $s_i: v \to s_i(v) = v 2\frac{(v|\alpha_i)}{(\alpha_i|\alpha_i)}\alpha_i$
- But in Clifford algebra have  $n \cdot a = \frac{1}{2}(na + an)$  so reassembles into (note doubly covered by n and -n) sandwiching

$$a' = -nan$$

 So both Coxeter and Clifford frameworks are ideally suited to describing reflections – combine the two

#### Rotations

• Generate a rotation in the plane  $m \wedge n$  when compounding two reflections wrt n then m:

$$a'' = mnanm \equiv Ra\tilde{R}$$

where R=mn is called a rotor and a tilde denotes reversal of the order of the constituent vectors  $(R\tilde{R}=1)$ 

Multivectors transform covariantly e.g.

$$MN \rightarrow (RM\tilde{R})(RN\tilde{R}) = RM\tilde{R}RN\tilde{R} = R(MN)\tilde{R}$$

so transform double-sidedly

Spinors form a group, which gives a representation of the Spin group Spin(n) – they transform single-sidedly (obvious it's a double (universal) cover)

### Geometric Algebra and orthogonal transformations

- Cartan-Dieudonné: every isometry is at most *d* reflections
- Since have a double cover of reflections (n and -n) we have a double cover of O(p,q): Pin(p,q)

$$x'=\pm n_1n_2\ldots n_kxn_k\ldots n_2n_1$$

- Pinors = products of vectors  $n_1 n_2 ... n_k$  encode orthogonal transformations via 'sandwiching'
- Cartan-Dieudonné: rotations are an even number of reflections: Spin(p,q) doubly covers SO(p,q)

#### 3D Platonic Solids

- There are 5 Platonic solids
- Tetrahedron (self-dual) (A<sub>3</sub>)
- Dual pair octahedron and cube (B<sub>3</sub>)
- Dual pair icoshahedron and dodecahedron  $(H_3)$
- Only the octahedron is a root system (actually for  $(A_1^3)$ )

#### Clifford and Coxeter: Platonic Solids

Platonic Solid	Group	root system
Tetrahedron	<i>A</i> <sub>3</sub>	Cuboctahedron
	$A_1^3$	Octahedron
Octahedron	<i>B</i> <sub>3</sub>	Cuboctahedron
Cube		+Octahedron
Icosahedron	$H_3$	Icosidodecahedron
Dodecahedron		

- Platonic Solids have been known for millennia
- Described by Coxeter groups

#### 4D 'Platonic Solids'

- In 4D, there are 6 analogues of the Platonic Solids:
- 5-cell (self-dual) (A<sub>4</sub>)
- 24-cell (self-dual)  $(D_4)$  a 24-cell and its dual together are the  $F_4$  root system
- Dual pair 16-cell and 8-cell (B<sub>4</sub>)
- Dual pair 600-cell and 120-cell  $(H_4)$
- These are 4D analogues of the Platonic Solids: regular convex 4-polytopes

#### 4D 'Platonic Solids'

- 24-cell, 16-cell and 600-cell are all root systems, as is the related *F*<sub>4</sub> root system
- 8-cell and 120-cell are dual to a root system, so in 4D out of 6
   Platonic Solids only the 5-cell (corresponding to A<sub>n</sub> family) is not related to a root system!
- The 4D Platonic solids are not normally thought to be related to the 3D ones except for the boundary cells
- They have very unusual automorphism groups
- Some partial case-by-case algebraic results in terms of quaternions – here we show a uniform construction offering geometric understanding

### Mysterious Symmetries of 4D Polytopes

#### Spinorial symmetries

Spiriorial Symmetries			
rank 4	Φ	Symmetry	
D <sub>4</sub> 24-cell	24	$2 \cdot 24^2 = 576$	
F <sub>4</sub> lattice	48	$48^2 = 2304$	
H <sub>4</sub> 600-cell	120	$120^2 = 14400$	
A <sub>1</sub> 16-cell	8	$3! \cdot 8^2 = 384$	
$A_2 \oplus A_2$ prism	12	$12^2 = 144$	
$H_2 \oplus H_2$ prism	20	$20^2 = 400$	
$I_2(n) \oplus I_2(n)$	2 <i>n</i>	$(2n)^{2}$	

Similar for Grand Antiprism ( $H_4$  without  $H_2 \oplus H_2$ ) and Snub 24-cell (21 without 2T).

#### A new connection

- Platonic Solids have been known for millennia; described by Coxeter groups
- Concatenating reflections gives Clifford spinors (binary polyhedral groups)
- These induce 4D root systems  $\psi = a_0 + a_i le_i \Rightarrow \psi \tilde{\psi} = a_0^2 + a_1^2 + a_2^2 + a_3^2$
- 4D analogues of the Platonic Solids and give rise to 4D Coxeter groups

#### Overview

- Introduction
  - Coxeter groups and root systems
  - Clifford algebras
  - 'Platonic' Solids

- 2 Combining Coxeter and Clifford
  - The Induction Theorem from 3D to 4D
  - Automorphism Groups
  - Trinities and McKay correspondence

## Induction Theorem – root systems

• Theorem: 3D spinor groups give root systems.

1. 
$$\Phi \cap \mathbb{R}\alpha = \{-\alpha, \alpha\} \ \forall \ \alpha \in \Phi$$
2.  $s_{\alpha}\Phi = \Phi \ \forall \ \alpha \in \Phi$ 

- Proof: 1. R and -R are in a spinor group by construction, 2. closure under reflections is guaranteed by the closure property of the spinor group
- Induction Theorem: Every rank-3 root system induces a rank-4 root system (and thereby Coxeter groups)
- Counterexample: not every rank-4 root system is induced in this way

### Induction Theorem – automorphism

- So induced 4D polytopes are actually root systems.
- Clear why the number of roots  $|\Phi|$  is equal to |G|, the order of the spinor group
- Spinor group is trivially closed under conjugation, left and right multiplication. Results in non-trivial symmetries when viewed as a polytope/root system.
- Now explains symmetry of the polytopes/root system and thus the order of the rank-4 Coxeter group
- Theorem: The automorphism group of the induced root system contains two factors of the respective spinor group acting from the left and the right.

## Recap: Clifford algebra and reflections & rotations

 Clifford algebra is very efficient at performing reflections via sandwiching

$$a' = -nan$$

 Generate a rotation when compounding two reflections wrt n then m (Cartan-Dieudonné theorem):

$$a''=m$$
nanm $\equiv Ra ilde{R}$ 

where R=mn is called a spinor and a tilde denotes reversal of the order of the constituent vectors  $(R\tilde{R}=1)$ 

# Spinors from reflections

- The 3D Coxeter groups that are symmetry groups of the Platonic Solids:
- The 6/12/18/30 reflections in  $A_1 \times A_1 \times A_1/A_3/B_3/H_3$  generate 8/24/48/120 spinors.
- E.g.  $\pm e_1$ ,  $\pm e_2$ ,  $\pm e_3$  give the 8 spinors  $\pm 1, \pm e_1e_2, \pm e_2e_3, \pm e_3e_1$
- The discrete spinor group is isomorphic to the quaternion group Q / binary tetrahedral group 2T/ binary octahedral group 2O/ binary icosahedral group 2I).

### Spinors and Polytopes

- The space of Cl(3)-spinors and quaternions have a 4D Euclidean signature:  $\psi = a_0 + a_i I e_i \Rightarrow \psi \tilde{\psi} = a_0^2 + a_1^2 + a_2^2 + a_3^2$
- Can reinterpret spinors in  $\mathbb{R}^3$  as vectors in  $\mathbb{R}^4$
- Then the spinors constitute the vertices of the 16-cell, 24-cell, 24-cell and dual 24-cell and the 600-cell
- These are 4D analogues of the Platonic Solids: regular convex 4-polytopes

### **Exceptional Root Systems**

- The 16-cell, 24-cell, 24-cell and dual 24-cell and the 600-cell are in fact the root systems of  $A_1 \times A_1 \times A_1 \times A_1$ ,  $D_4$ ,  $F_4$  and  $H_4$
- Exceptional phenomena:  $D_4$  (triality, important in string theory),  $F_4$  (largest lattice symmetry in 4D),  $H_4$  (largest non-crystallographic symmetry)
- Exceptional  $D_4$  and  $F_4$  arise from series  $A_3$  and  $B_3$
- In fact, as we have seen one can strengthen this statement on inducing polytopes to a statement on inducing root systems

#### Root systems in three and four dimensions

The spinors generated from the reflections contained in the respective rank-3 Coxeter group via the geometric product are realisations of the binary polyhedral groups Q, 2T, 2O and 2I, which were known to generate (mostly exceptional) rank-4 groups, but not known why, and why the 'mysterious symmetries'.

rank-3 group	diagram	binary	rank-4 group	diagram
$A_1 \times A_1 \times A_1$	0 0 0	Q	$A_1 \times A_1 \times A_1 \times A_1$	0 0 0 0
A <sub>3</sub>	0—0—0	2 <i>T</i>	$D_4$	~~ <u></u>
B <sub>3</sub>	<u></u>	20	F <sub>4</sub>	4
Н3	<u></u>	21	H <sub>4</sub>	<u> </u>

#### General Case of Induction

Only remaining case is what happens for  $A_1 \oplus I_2(n)$  - this gives a doubling  $I_2(n) \oplus I_2(n)$ 

	2( ) ~ 2( )
rank 3	rank 4
$A_3$	$D_4$
B <sub>3</sub>	$F_4$
$H_3$	$H_4$
$A_1^3$	$A_1^4$
$A_1 \oplus A_2$	$A_2 \oplus A_2$
$A_1 \oplus H_2$	$H_2 \oplus H_2$
$A_1 \oplus I_2(n)$	$I_2(n) \oplus I_2(n)$

Can do an analogous construction using 3 roots to generate a discrete octonion group. These are again root systems, however just two copies of the above.

### Automorphism Groups

- So induced 4D polytopes are actually root systems via the binary polyhedral groups.
- Clear why the number of roots  $|\Phi|$  is equal to |G|, the order of the spinor group.
- Spinor group is trivially closed under conjugation, left and right multiplication. Results in non-trivial symmetries when viewed as a polytope/root system.
- Now explains symmetry of the polytopes/root system and thus the order of the rank-4 Coxeter group
- Theorem: The automorphism group of the induced root system contains two factors of the respective spinor group acting from the left and the right.

# Spinorial Symmetries of 4D Polytopes

#### Spinorial symmetries

rank 3	Φ	W	rank 4	Φ	Symmetry
$A_3$	12	24	D <sub>4</sub> 24-cell	24	$2 \cdot 24^2 = 576$
B <sub>3</sub>	18	48	F <sub>4</sub> lattice	48	$48^2 = 2304$
<i>H</i> <sub>3</sub>	30	120	H <sub>4</sub> 600-cell	120	$120^2 = 14400$
$A_1^3$	6	8	A <sub>1</sub> 16-cell	8	$3! \cdot 8^2 = 384$
$A_1 \oplus A_2$	8	12	$A_2 \oplus A_2$ prism	12	$12^2 = 144$
$A_1 \oplus H_2$	12	20	$H_2 \oplus H_2$ prism	20	$20^2 = 400$
$A_1 \oplus I_2(n)$	n+2	2n	$I_2(n) \oplus I_2(n)$	2 <i>n</i>	$(2n)^{2}$

Similar for Grand Antiprism ( $H_4$  without  $H_2 \oplus H_2$ ) and Snub 24-cell (21 without 2T). Additional factors in the automorphism group come from 3D Dynkin diagram symmetries!

## Some non-Platonic examples of spinorial symmetries

- Grand Antiprism: the 100 vertices achieved by subtracting 20 vertices of  $H_2 \oplus H_2$  from the 120 vertices of the  $H_4$  root system 600-cell two separate orbits of  $H_2 \oplus H_2$
- This is a semi-regular polytope with automorphism symmetry  $\operatorname{Aut}(H_2 \oplus H_2)$  of order  $400 = 20^2$
- Think of the  $H_2 \oplus H_2$  as coming from the doubling procedure? (Likewise for  $Aut(A_2 \oplus A_2)$  subgroup)
- Snub 24-cell: 2T is a subgroup of 2I so subtracting the 24 corresponding vertices of the 24-cell from the 600-cell, one gets a semiregular polytope with 96 vertices and automorphism group  $2T \times 2T$  of order  $576 = 24^2$ .

### Sub root systems

- The above spinor groups had spinor multiplication as the group operation
- But also closed under twisted conjugation corresponds to closure under reflections (root system property)
- If we take twisted conjugation as the group operation instead, we can have various subgroups
- These are the remaining 4D root systems e.g.  $A_4$  or  $B_4$

#### Arnold's Trinities

Arnold's observation that many areas of real mathematics can be complexified and quaternionified resulting in theories with a similar structure.

- ullet The fundamental trinity is thus  $(\mathbb{R},\mathbb{C},\mathbb{H})$
- The projective spaces  $(\mathbb{R}P^n, \mathbb{C}P^n, \mathbb{H}P^n)$
- The spheres  $(\mathbb{R}P^1 = S^1, \mathbb{C}P^2 = S^2, \mathbb{H}P^1 = S^4)$
- The Möbius/Hopf bundles  $(S^1 \rightarrow S^1, S^4 \rightarrow S^2, S^7 \rightarrow S^4)$
- The Lie Algebras  $(E_6, E_7, E_8)$
- The symmetries of the Platonic Solids  $(A_3, B_3, H_3)$
- The 4D groups  $(D_4, F_4, H_4)$
- New connections via my Clifford spinor construction (see McKay correspondence)

#### Platonic Trinities

- Arnold's connection between (A<sub>3</sub>, B<sub>3</sub>, H<sub>3</sub>) and (D<sub>4</sub>, F<sub>4</sub>, H<sub>4</sub>) is very convoluted and involves numerous other trinities at intermediate steps:
- Decomposition of the projective plane into Weyl chambers and Springer cones
- The number of Weyl chambers in each segment is 24 = 2(1+3+3+5), 48 = 2(1+5+7+11), 120 = 2(1+11+19+29)
- Notice this miraculously matches the quasihomogeneous weights ((2,4,4,6),(2,6,8,12),(2,12,20,30)) of the Coxeter groups  $(D_4,F_4,H_4)$
- Believe the Clifford connection is more direct

### A unified framework for polyhedral groups

Group	Discrete subgroup	Action Mechanism
SO(3) O(3) Spin(3) Pin(3)	rotational (chiral) reflection (full/Coxeter) binary pinor	$egin{aligned} x & ightarrow  ilde{R}xR \ x & ightarrow \pm  ilde{A}xA \ (R_1,R_2) & ightarrow R_1R_2 \ (A_1,A_2) & ightarrow A_1A_2 \end{aligned}$

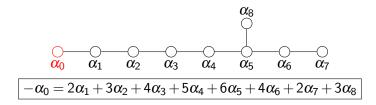

- e.g. the chiral icosahedral group has 60 elements, encoded in Clifford by 120 spinors, which form the binary icosahedral group
- together with the inversion/pseudoscalar I this gives 60 rotations and 60 rotoinversions, i.e. the full icosahedral group H<sub>3</sub> in 120 elements (with 240 pinors)
- all three are interesting groups, e.g. in neutrino and flavour physics for family symmetry model building

### Some Group Theory: chiral, full, binary, pin

- Easy enough to calculate conjugacy classes etc of pinors in Clifford algebra
- Chiral (binary) polyhedral groups have irreps
- tetrahedral (12/24): 1, 1', 1", 2<sub>s</sub>, 2'<sub>s</sub>, 2"<sub>s</sub>, 3
- octahedral (24/48): 1, 1', 2, 2<sub>s</sub>, 2'<sub>s</sub>, 3, 3', 4<sub>s</sub>
- icosahedral (60/120): 1,  $2_s$ ,  $2'_s$ , 3,  $\bar{3}$ , 4,  $4_s$ , 5,  $6_s$
- Binary groups are discrete subgroups of SU(2) and all thus have a  $2_s$  spinor irrep
- Connection with the McKay correspondence!

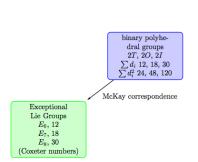

# Affine extensions – $E_8^=$

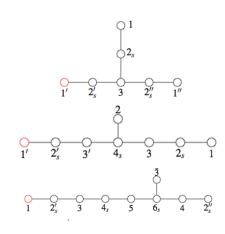

AKA  $E_8^+$  and along with  $E_8^{++}$  and  $E_8^{+++}$  thought to be the underlying symmetry of String and M-theory

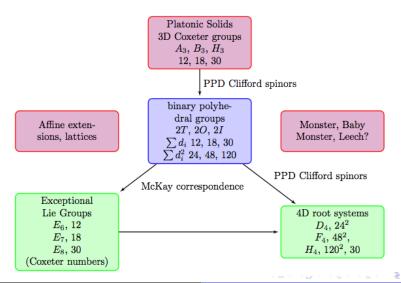

Also interesting from a pure mathematics point of view:  $E_8$  lattice, McKay correspondence and Monstrous Moonshine.

## The McKay Correspondence

## The McKay Correspondence

## The McKay Correspondence

More than E-type groups: the infinite family of 2D groups, the cyclic and dicyclic groups are in correspondence with  $A_n$  and  $D_n$ , e.g. the quaternion group Q and  $D_4^+$ . So McKay correspondence not just a trinity but ADE-classification. We also have  $l_2(n)$  on top of the trinity  $(A_3, B_3, H_3)$ 

rank-3 group	diagram	binary	rank-4 group	diagram	Lie algebra	diagram
$A_1 \times A_1 \times A_1$	0 0 0	Q	$A_1 \times A_1 \times A_1 \times A_1$	0 0 0 0	$D_4^+$	
A <sub>3</sub>	o—o—o	2 <i>T</i>	$D_4$		$E_6^+$	
B <sub>3</sub>	<u>4</u> 0	20	F <sub>4</sub>	<u></u> 4	E <sub>7</sub> <sup>+</sup>	
H <sub>3</sub>	<u>5</u>	21	H <sub>4</sub>	o—o—o 5	$E_8^+$	•

# 4D geometry is surprisingly important for HEP

- 4D root systems are surprisingly relevant to HEP
- $A_4$  is SU(5) and comes up in Grand Unification
- $D_4$  is SO(8) and is the little group of String theory
- In particular, its triality symmetry is crucial for showing the equivalence of RNS and GS strings
- $B_4$  is SO(9) and is the little group of M-Theory
- $F_4$  is the largest crystallographic symmetry in 4D and  $H_4$  is the largest non-crystallographic group
- The above are subgroups of the latter two
- Spinorial nature of the root systems could have surprising consequences for HEP

## Quaternions and Clifford Algebra

- The unit spinors  $\{1; le_1; le_2; le_3\}$  of Cl(3) are isomorphic to the quaternion algebra  $\mathbb{H}$
- The 3D Hodge dual of a vector is a pure bivector which corresponds to a pure quaternion, and their products are identical (up to sign)

## Discrete Quaternion groups

- The 8 quaternions of the form  $(\pm 1,0,0,0)$  and permutations are called the Lipschitz units, and form a realisation of the quaternion group in 8 elements.
- The 8 Lipschitz units together with  $\frac{1}{2}(\pm 1, \pm 1, \pm 1, \pm 1)$  are called the Hurwitz units, and realise the binary tetrahedral group of order 24. Together with the 24 'dual' quaternions of the form  $\frac{1}{\sqrt{2}}(\pm 1, \pm 1, 0, 0)$ , they form a group isomorphic to the binary octahedral group of order 48.
- The 24 Hurwitz units together with the 96 unit quaternions of the form  $(0,\pm\tau,\pm1,\pm\sigma)$  and even permutations, are called the Icosians. The icosian group is isomorphic to the binary icosahedral group with 120 elements.

## Quaternionic representations of 3D and 4D Coxeter groups

- Groups  $E_8$ ,  $D_4$ ,  $F_4$  and  $H_4$  have representations in terms of quaternions
- Extensively used in the high energy physics/quasicrystal/Coxeter/polytope literature and thought of as deeply significant, though not really clear why
- e.g.  $H_4$  consists of 120 elements of the form  $(\pm 1,0,0,0)$ ,  $\frac{1}{2}(\pm 1,\pm 1,\pm 1,\pm 1)$  and  $(0,\pm \tau,\pm 1,\pm \sigma)$
- Seen as remarkable that the subset of the 30 pure quaternions is a realisation of  $H_3$  (a sub-root system)
- Similarly,  $A_3$ ,  $B_3$ ,  $A_1 \times A_1 \times A_1$  have representations in terms of pure quaternions
- Will see there is a much simpler geometric explanation

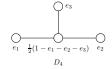

## Quaternionic representations used in the literature

$$\bigcirc_{e_1} \qquad \bigcirc_{e_2} \qquad \bigcirc_{e_3} 
A_1 \times A_1 \times A_1$$

$$\bigcap_{1} \quad \bigcap_{e_{1}} \quad \bigcap_{e_{2}} \quad \bigcap_{e_{3}}$$

$$A_{1} \times A_{1} \times A_{1} \times A_{1}$$

$$\begin{array}{c|c}
 & 5 & \bigcirc \\
-e_1 & \frac{1}{2}(\tau e_1 + e_2 + \sigma e_3) & -e_2
\end{array}$$

## Demystifying Quaternionic Representations

- 3D: Pure quaternions = Hodge dualised (pseudoscalar) root vectors
- In fact, they are the simple roots of the Coxeter groups
- 4D: Quaternions = disguised spinors but those of the 3D
   Coxeter group i.e. the binary polyhedral groups!
- This relation between 3D and 4D via the geometric product does not seem to be known
- Quaternion multiplication = ordinary Clifford reflections and rotations

## Demystifying Quaternionic Representations

- Pure quaternion subset of 4D groups only gives 3D group if the 3D group contains the inversion/pseudoscalar /
- e.g. does not work for the tetrahedral group  $A_3$ , but  $A_3 \rightarrow D_4$  induction still works, with the central node essentially 'spinorial'
- In fact, it goes the other way around: the 3D groups induce the 4D groups via spinors
- The rank-4 groups are also generated (under quaternion multiplication) by two quaternions we can identify as  $R_1 = \alpha_1 \alpha_2$  and  $R_2 = \alpha_2 \alpha_3$
- Can see these are 'spinor generators' and how they don't really contain any more information/roots than the rank-3 groups alone

## Quaternions vs Clifford versors

- Sandwiching is often seen as particularly nice feature of the quaternions giving rotations
- This is actually a general feature of Clifford algebras/versors in any dimension; the isomorphism to the quaternions is accidental to 3D
- However, the root system construction does not necessarily generalise
- 2D generalisation merely gives that  $I_2(n)$  is self-dual
- Octonionic generalisation just induces two copies of the above 4D root systems, e.g.  $A_3 \rightarrow D_4 \oplus D_4$

#### Conclusions

- Novel connection between geometry of 3D and 4D
- In fact, 3D seems more fundamental contrary to the usual perspective of 3D subgroups of 4D groups
- Spinorial symmetries
- Clear why spinor group gives a root system and why two factors of the same group reappear in the automorphism group
- Novel spinorial perspective on 4D geometry
- Accidentalness of the spinor construction and exceptional 4D phenomena
- Connection with Arnold's trinities, the McKay correspondence and Monstrous Moonshine

The Induction Theorem – from 3D to 4D Automorphism Groups Trinities and McKay correspondence

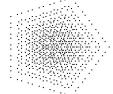

Thank you!

#### Motivation: Viruses

- Geometry of polyhedra described by Coxeter groups
- Viruses have to be 'economical' with their genes
- Encode structure modulo symmetry
- Largest discrete symmetry of space is the icosahedral group
- Many other 'maximally symmetric' objects in nature are also icosahedral: Fullerenes & Quasicrystals
- But: viruses are not just polyhedral they have radial structure. Affine extensions give translations

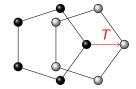

Unit translation along a vertex of a unit pentagon

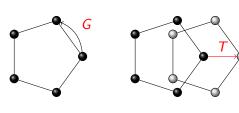

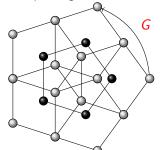

#### Unit translation along a vertex of a unit pentagon

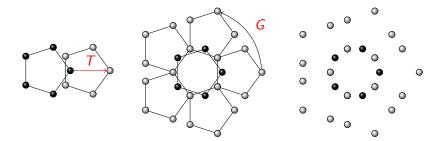

Unit translation along a vertex of a unit pentagon

A random translation would give 5 secondary pentagons, i.e. 25 points. Here we have degeneracies due to 'coinciding points'.

Translation of length  $\tau = \frac{1}{2}(1+\sqrt{5}) \approx 1.618$  (golden ratio)

Looks like a virus or carbon onion

## Extend icosahedral group with distinguished translations

- Radial layers are simultaneously constrained by affine symmetry
- Works very well in practice: finite library of blueprints
- Select blueprint from the outer shape (capsid)
- Can predict inner structure (nucleic acid distribution) of the virus from the point array

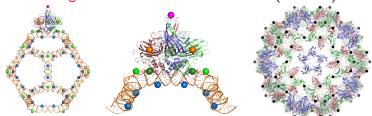

Affine extensions of the icosahedral group (giving translations) and their classification.

## Use in Mathematical Virology

- Suffice to say point arrays work very exceedingly well in practice. Two papers on the mathematical (Coxeter) aspects.
- Implemented computational problem in Clifford some very interesting mathematics comes out as well (see later).

## Extension to fullerenes: carbon onions

- Extend idea of affine symmetry to other icosahedral objects in nature: football-shaped fullerenes
- Recover different shells with icosahedral symmetry from affine approach: carbon onions ( $C_{60} C_{240} C_{540}$ )

## Extension to fullerenes: carbon onions

- Extend idea of affine symmetry to other icosahedral objects in nature: football-shaped fullerenes
- Recover different shells with icosahedral symmetry from affine approach: carbon onions  $(C_{80} - C_{180} - C_{320})$

# Applications of affine extensions of non-crystallographic root systems

There are interesting applications to quasicrystals, viruses or carbon onions, but here concentrate on the mathematical aspects
