Abstract

Introduction: Emotional dispositions have been found to influence outcomes and have applications in many areas, such as in the clinical, health, social, educational, and organizational domains. Specifically, they may influence individuals' addictive behaviour tendencies. The aim of this study was to investigate the convergent validity between two questionnaires measuring individual differences linked to emotional dispositions, the Profile of Emotional Competences (PEC) full-form and the Trait Emotional Intelligence Questionnaire (TEIQue) full-form. Examining the convergent validity will identify the similarities and the unique aspects of each questionnaire. Our hypotheses were based on relationships displaying large effect sizes ($r > .50$). **Methodology:** A sample of 1026 participants took part in this study ($M_{\text{age}} = 21.35$ years old, age range = 18-30). Participants completed both the PEC and the TEIQue in a counterbalanced order. **Results:** Results indicated large overlaps between the two questionnaires, however two main differences emerged: first, the PEC allows to capture precisely the emotional dispositions at the intrapersonal and interpersonal levels, while the TEIQue mixes both levels; second, the competence "using emotions", both for one's own emotions and for others' emotions, is not comprehensively reflected in the TEIQue. **Discussion:** Overall, the PEC may help to capture more specifically the distinction between intrapersonal and interpersonal emotional competences. Future research should investigate comparatively the criterion validity of both questionnaires with specific outcome variables. **Practical implications:** Future research and applied work with addiction aiming at clarifying the implication of both intrapersonal and interpersonal emotional competences may consider to rather use the PEC than the TEIQue.

Keywords: emotional intelligence, emotional competences, emotion identification, emotion expression, emotion understanding, emotion regulation, emotion use

Introduction

Individual differences linked to emotional dispositions at the trait level have been referred to as trait emotional intelligence (EI) or emotional competences (EC). EI/EC refer to the self-perception of emotional abilities at a trait level, that is to say, the typical performance of people in terms of identifying, expressing, understanding, regulating, and using emotions, for themselves and for others, in order to adapt to their environment (Brasseur et al., 2013; Petrides et al., 2016; Scherer, 2007). The field of EI and EC at the trait level has applications in the areas of clinical, health, social, educational, organizational, and developmental psychology (Petrides et al., 2016; Sarrionandia & Mikolajczak, 2020). Specifically regarding addiction, higher EI was found to be a protective factor against smoking (Kun & Demetrovics, 2010; Torres et al., 2020), alcohol use, and illicit drug use (Kun & Demetrovics, 2010). Furthermore, technological addictions are of recent interest (Gugliandolo et al., 2019), and EI has been found to be a protective factor against problematic internet behaviour (Arrivillaga et al., 2020; Hsieh et al., 2018; Sechi et al., 2020; Wang & Zhang, 2020), and smartphone use (Arrivillaga et al., 2020; Busch & McCarthy, 2021; Mascia et al., 2020). Finally, EI and EC may not only act as protective factors against addiction behaviours, but may also represent an important adjuvant for counsellors providing support for people with addiction, given addiction counsellors with higher EI have been found to display higher cultural empathy (Smith et al., 2020). Taken together, these findings showcase the societal relevance of EI and EC to better understand addiction.

Concerning terminology, EI has been mostly used since the concept was defined by Salovey and Mayer (1990). However, researchers have called for a terminology shift towards EC (Brasseur et al., 2013; Scherer, 2007). Specifically, there is growing evidence that unlike intelligence, EC can be taught and improved (Brasseur et al., 2013; Hodzic et al., 2017). However, the question of EC and EI measurement remains critical (Laborde & Allen, 2016), and there is a continuous need for measurement evaluation, given the fast-paced theoretical

advancements in this area (Mikolajczak, 2010), and because of the regular development of new scales (e.g., Pekaar et al., 2018). Therefore, the aim of this study is to analyse the convergent validity of two questionnaires aimed to assess EI/EC at the trait level, the trait emotional intelligence questionnaire (TEIQue; Petrides, 2009) and the profile for emotional competences (PEC; Brasseur et al., 2013).

The TEIQue (Petrides, 2009) measures a constellation of emotion-related self-perceptions situated at the lower levels of personality hierarchies (Petrides et al., 2007), reflecting how people deal with their own and others' emotions. This questionnaire has been utilised in numerous studies, which among other aspects, displayed higher predictive ability on a range of life outcomes in comparison to established personality constructs such as the big five (e.g., Siegling et al., 2015). Moreover, research has reported that EI measured with the TEIQue was connected to genetic factors (van der Linden et al., 2018; Vernon et al., 2008) and to biological mechanisms linked to stress, such as the stress hormone cortisol (Laborde et al., 2014; Mikolajczak et al., 2007), and with a marker of self-regulation, heart rate variability (Laborde et al., 2011; Laborde et al., 2015). The TEIQue is available in two versions (Petrides, 2009), a full-form version (153 items, 4 factors, 15 subscales) and a short-form version (30 items, 4 factors). The definition of the TEIQue subscales is provided in Table 1.

Insert Table 1 near here

The PEC (Brasseur et al., 2013) measures how individuals deal with intrapersonal and interpersonal information, on the five core EC, namely identification, expression, understanding, regulation, and use of emotions. The main difference with the TEIQue is that the PEC splits explicitly each of the five main EC into two dimensions, intrapersonal and interpersonal, while the TEIQue integrates both intrapersonal and interpersonal information in its factors (Brasseur et al., 2013; Nozaki et al., 2019; Petrides, 2009). This distinction allows to better understand the relationship of EC with outcomes (Pekaar et al., 2020), given certain aspects may be more related to intrapersonal EC, such as health (Mikolajczak et al., 2015;

Nozaki & Koyasu, 2016), perceived stress (You et al., 2020), or executive functions (Vaughan et al., 2020), while other may be more connected to interpersonal EC, such as relationships (Brasseur et al., 2013). This intra/interpersonal distinction allows as well to better understand the relationship of EC with established personality constructs, such as with the Big five (Laborde et al., 2020). Despite the PEC being a relatively new instrument in comparison to the TEIQue, empirical evidence has demonstrated its ability to predict subjective health and happiness (Nozaki & Koyasu, 2016) as well as objective health outcomes (Mikolajczak et al., 2015). Furthermore, building on the distinction between intrapersonal and interpersonal EC, people with higher interpersonal EC were found to show higher helpful behaviour towards ostracized people (Nozaki, 2015). Additionally, taking into account the interaction between intrapersonal and interpersonal EC may help to better understand their relationship with specific psychological and physiological outcomes, such as parental burnout (Bayot et al., 2021) or Anorexia Nervosa (Doba & Nandrino, 2020). The PEC full-form (Brasseur et al., 2013) has 50 items, 2 factors, and 10 subscales, while the PEC short-form has 20 items, 2 factors, and 10 subscales (Mikolajczak et al., 2014). The definition of the subscales is provided in Table 2.

Insert Table 2 near here

To date, the convergent validity between the TEIQue and the PEC has only been briefly investigated during the validation process of the PEC (Brasseur et al., 2013). However, in this study, the TEIQue short-form was used, and therefore only a comparison with the global trait EI (i.e., the average score of all items) could be realized. Findings showed that the PEC global score was significantly highly correlated with the TEIQue global score ($r = .77$), however the correlation was higher for the PEC intrapersonal factor ($r = .78$) than with the PEC interpersonal factor ($r = .52$). This finding would suggest that the TEIQue captures more intrapersonal than interpersonal aspects. Taking the TEIQue short-form to evaluate the convergent validity with the PEC may not be the most optimal choice, even if the factor

structure is expected to be similar between the TEIQue full-form and short-form (Laborde et al., 2016). For example, the TEIQue short-form has been shown to produce systematically higher scores than the TEIQue long-form (Laborde et al., 2017), though both questionnaires remain highly correlated and predict outputs in a similar way. Therefore, to better analyse the convergent validity between the two questionnaires, we will use the full-form versions for both the TEIQue and the PEC.

In assessing the convergent validity between the TEIQue full-form and the PEC full-form, we will recruit a large sample ($N > 1000$). Given our large sample size and the likely high amount of significant correlations we will find, we will base our hypotheses on the effect size of the relationships, and predict only the relationships where large effect sizes, with $r > .50$ (Cohen, 1988), can be expected based on theoretical considerations (Brasseur et al., 2013; Petrides, 2009). Hypotheses take as a reference point the PEC subscales and factors, based on their organization into intrapersonal and interpersonal EC (see Table 3). For clarity and space matters, hypotheses are only made either at the subscale level, or at the factor/global trait level. Therefore, no hypotheses are made between subscales of one questionnaire and factors of the other questionnaire.

Insert Table 3 near here

Methods

Participants

A total of 1026 students were involved in this research (516 male, 510 female, mean age = 21.35 years old, age range = 18-30 years old). Participants had to be at least 18 to participate, and to study at the local University. There were no further inclusion nor exclusion criteria.

Instruments

Trait Emotional Intelligence Questionnaire (TEIQue)

The Spanish version of the TEIQue was used in this research (Petrides, 2009). The TEIQue full-form (Petrides, 2009) contains 153 items, 15 subscales, and four factors. The four factors

are well-being (e.g., “On the whole, I’m pleased with my life”), self-control (e.g., “Others admire me for being relaxed.”), emotionality (e.g., “I often pause and think about my feelings”), and sociability (e.g., “I would describe myself as a good negotiator”). The 15 subscales are self-esteem, emotion expression, motivation, emotion regulation, happiness, empathy, social competence, impulsiveness, emotion perception, stress management, emotion management, optimism, relationship skills, adaptability, and assertiveness. Items are scored on a Likert-scale from 1 (completely disagree) to 7 (completely agree). Cronbach’s α are displayed in Table 4.

Insert Table 4 here

Profile of emotional competences

The PEC (Brasseur et al., 2013) contains 50 items, assessed from 1 (strongly disagree) to 5 (strongly agree) on a Likert-scale. It measures five core EC separately, distinctly for one’s own and others’ emotions. Ten subscales can be thus calculated: identification of one’s emotions, identification of others’ emotions, understanding of one’s emotions, understanding of others’ emotions, expression of one’s emotions, listening to others’ emotions, regulation of one’s emotions, regulation of others’ emotions, use of one’s emotions, use of others’ emotions. Three global scores can be calculated: an intrapersonal EC score, an interpersonal EC score, and a global EC score. Examples of items are “during an argument, I can’t identify whether I am sad or angry” and “my emotions inform me of what is important to me”. Given the PEC was not available in Spanish, a preliminary step was to validate the PEC to Spanish. This preliminary step is described in the procedure and data analysis sections. Cronbach’s α of the validated version are displayed in Table 4.

Procedure

Given the PEC was not available in Spanish, the first step was to translate and validate the questionnaire into Spanish. To achieve this aim, guidelines from Van de Vijver and

Hambleton (1996) were followed. A double back-translation procedure was used to adapt the questionnaire from English to Spanish. Two fully bilingual Spanish University professors translated the questionnaire into Spanish, which was then back translated independently by two fully bilingual English native Professors (originating from Great Britain), all with educational background in psychology. Items were discussed until consensus was reached among the authors.

Once the PEC was translated to Spanish, the data collection for this study could start. The Ethics committee of a University in Spain provided ethical clearance for the study prior to data collection. Participants were recruited via research assistants trained to questionnaire data collection by the second author. Taking part in this research protocol was not part of a course requirement, and participants did not receive any payment in exchange of participation. Participants were presented with a brief description of the study objective and were then given the opportunity to participate. The research assistants made clear that participation was voluntary, anonymous, and that participants could withdraw at any time. Written informed consent was obtained from all study participants. Questionnaires were completed in a quiet classroom setting and took between 35 and 45 minutes to complete. The order of the two questionnaires was counterbalanced.

Data analysis

Data of the PEC and TEIQue were first checked for normality. As our preliminary aim was to confirm the structure of the PEC in Spanish, we ran a Confirmatory Factor Analysis (CFA) with AMOS 17 on our sample, with the following fit indices: the χ^2 statistic, the comparative fit index (CFI), the Tucker-Lewis index (TLI), the root mean square of approximation (RMSEA), the standardized root mean square residual (SRMR). The χ^2 statistic constitutes a subjective index of fit, with large chi-square values relative to degrees of freedom indicating a poor fit, and small values indicating a good fit (Jöreskog, 1993). However, χ^2 is quite sensitive to sample size and inflates with large samples (Raykov, 1998). For the CFI and the

TLI values between .90 and .94 indicate acceptable fit, whereas values of .95 and higher indicate a relatively good fit (Hu & Bentler, 1999). For the RMSEA values smaller than .08 indicate acceptable fit, whereas values smaller than .05 indicate a good fit. For SRMR a good fit is indicated by values smaller than .08 (Hu & Bentler, 1999).

To analyse the convergent validity between the PEC and the TEIQue, bivariate Pearson correlation analyses were run. Given the large sample size and the likely high associations between two self-report questionnaires aiming to assess EI at the trait level, we formulated our hypotheses not only taking into account the significance level but also the effect size, considering only large effect sizes, so with $r > .50$.

Results

CFA

As a model for the CFA, we took the ten subscales and the two main factors of the PEC to see whether the original structure would replicate in the Spanish sample. The first CFA indicated acceptable fit to the data: $\chi^2 = 299.161$, $df = 34$, $p < .001$, CFI = .93, TLI = .90, RMSEA = .08, SRMR = .05. However, analysis of the modification indices (M.I.) suggested that correlating the error variance between two subscales from the interpersonal factor, namely “regulating others’ emotions” and “using others’ emotions” would improve model fit (value modification index = 142.273). Thus, our final CFA model indicated a good fit to the data supporting the PEC factor structure in a Spanish sample: $\chi^2 = 146.049$, $df = 33$, $p < .001$, CFI = .97, TLI = .96, RMSEA = .06, SRMR = .03.

Convergent Validity

An overview of the descriptive data can be seen in Table 4, and the correlation matrix can be seen in Table 5.

Insert Table 5 near here

Discussion

The aim of this study was to investigate the convergent validity between two questionnaires aiming to measure EI/EC at the trait level, the PEC and the TEIQue. Our hypotheses

regarding the associations between both questionnaires with large effect sizes were mostly confirmed, however certain discrepancies appeared, showing that both scales provide unique information.

Validation of the PEC to Spanish

As a preliminary step, we needed to validate the PEC to Spanish. While checking whether the data from the Spanish sample was matching the original structure of the PEC in 10 subscales and 2 factors, it appeared necessary to correlate the error variance of two dimensions from the interpersonal factor, “regulating others’ emotions” and “using others’ emotions”. According to Brasseur et al. (2013), the first dimension refers to being able to regulate stress or emotions in others when they are not appropriate to the context. The second refers to being able to use others’ emotions to help them improve reflection, decisions, and actions. Even though both competences are conceptually distinct; we observed some overlap between them, in that using others’ emotions could be seen as regulating others’ emotions with the objective to achieve a specific goal.

Convergent validity between the TEIQue and the PEC

The main aim of this study was to analyse the convergent validity between the TEIQue and the PEC, and we will discuss these in turn regarding our hypotheses (see Table 3) using the PEC subscales as a reference point.

Regarding the PEC subscale “identification of one’s emotions”, our hypothesis was confirmed, with a significant correlation and large effect size found with the TEIQue subscale “emotion perception (self and others)”. Regarding the PEC subscale “identification of others’ emotions”, our hypothesis is partially confirmed, given we found a significant correlation and large effect size with the TEIQue subscales “emotion perception (self and others)” and “empathy”, but not with relationship skills. This means that the TEIQue subscale “relationship skills”, defined as “being capable of having fulfilling personal relationships” (Petrides, 2009) captures additional variance beyond aspects related to identifying others’

emotions.

Regarding the PEC subscale “understanding of one’s emotions”, our hypothesis is confirmed, with a significant correlation and large effect size found with the TEIQue subscale “emotion perception (self and others)”. This finding illustrates the notion that perceiving emotion in the self and others plays a major role in being able to understand one’s emotions. Regarding the PEC subscale “understanding of others’ emotions”, our hypothesis is partially confirmed, given we found a significant correlation and large effect size with the TEIQue subscales “emotion perception (self and others)” and “empathy”, but not with the TEIQue subscale “relationship skills”. This means that the TEIQue subscale “relationship skills” captures additional variance beyond aspects related to understanding others’ emotions.

Regarding the PEC subscale “expressing one’s emotions”, our hypothesis was partially confirmed, with a significant correlation and large effect size found with the TEIQue subscale “emotion expression”. However, a significant correlation and large effect size was also found with the TEIQue subscale “emotion perception (self and others)”. This finding may illustrate the need to be able to perceive one’s own and others’ emotions, if one wants also to be able to express one’s emotions satisfactorily.

Regarding the PEC subscale “regulating one’s emotions”, our hypothesis is confirmed. We found as expected a significant correlation and large effect size with the TEIQue subscales “emotion regulation” and “stress management”. In the literature, stress is generally seen as a general adaptation mechanism, whereas emotions can be considered as responses triggered by specific appraisals, and have also a specific purpose regarding the goal to be achieved (Lazarus & Folkman, 1984; Scherer, 2005; Selye, 1951). This finding matches the PEC subscale “regulating one’s emotions” which encompasses both stress and emotion regulation (Brasseur et al., 2013). Regarding the PEC subscale “regulating others’ emotions”, our hypothesis was not confirmed. We expected a significant correlation and large effect sizes with two TEIQue subscales, “emotion management (others)” and “relationship skills”,

however these produced only moderate effect sizes. Overall, the PEC subscale “regulating others’ emotions” indicated no correlation with any of the TEIQue subscales, which argues that this subscale’s conceptual uniqueness is not captured by any TEIQue subscale.

Regarding the PEC subscale “using one’s emotions”, our hypothesis is confirmed, given only a significant correlation and moderate effect size was found with the TEIQue subscale “adaptability”. No other large effect was observed with any of the other TEIQue subscales. This finding suggests a unique feature of the PEC in contrast to the TEIQue in conceptualizing and measuring the use of one’s emotions, which is a core competence reflecting the integration of emotions into the optimization process of goal-directed behaviors.

Regarding the PEC subscale “using others’ emotions”, our hypothesis is partially validated. A significant correlation and large effect size was found with the TEIQue subscale “emotion regulation”, however no correlation was found with the TEIQue subscale “relationship skills”. This illustrates that the TEIQue subscale “relationship skills”, the ability in being capable of having fulfilling personal relationships (Petrides, 2009), does not integrate the notion of being able to use others’ emotions to help them make more adaptive decisions or realize more adaptive actions (Brasseur et al., 2013).

Regarding the PEC factor intrapersonal EC, our hypothesis was partially confirmed. As expected, we found intrapersonal EC to correlate significantly with large effect sizes with three TEIQue factors theoretically reflecting intrapersonal EC (i.e., well-being, self-control, and emotionality) and with the global TEIQue score, in line with the assumption that the TEIQue mostly focuses on intrapersonal EC (Brasseur et al., 2013; Petrides, 2009). In addition, we found a positive significant correlation with large effect size with the TEIQue factor sociability. This is potentially due to the fact that sociability encompasses two facets that may rely on interpersonal EC: social competence, which describes accomplished networkers with excellent social skills, and assertiveness, which reflects one’s willingness to stand up for their rights (Petrides, 2009). Regarding interpersonal EC, our hypothesis to find a

significant relationship with large effect sizes only with the TEIQue global score and with the TEIQue factors emotionality and sociability but not with the TEIQue factors well-being and self-control was confirmed. The TEIQue factors well-being and self-control showed only moderate correlations with the PEC factor interpersonal EC, while displaying at the same time large correlations with the PEC factor intrapersonal EC, which reflects that the TEIQue factors well-being and self-control are more strongly based on intrapersonal EC. Finally, our hypothesis regarding the PEC global score was partially confirmed, given it was correlated with large effect sizes with the TEIQue global score and all TEIQue factors but one. Specifically, only a moderate effect size was found between the global PEC score and the TEIQue factor self-control, meaning that self-control, the ability to control impulses and urges (Petrides, 2009), is not strongly reflected in the PEC global score.

To sum up, the PEC and the TEIQue show convergent validity in many aspects, but also displayed some unique features that make them conceptually different from each other. As evidenced by our findings, and in line with theoretical considerations underlying the PEC and the TEIQue (Brasseur et al., 2013; Nozaki et al., 2019; Petrides, 2009), the main distinction is that the PEC differentiates explicitly and systematically competences related to intrapersonal and interpersonal emotions, while the TEIQue aggregates both, with some TEIQue subscales spanning both aspects, while other TEIQue subscales target specifically only one aspect. This characteristic can be considered a limitation of the TEIQue, given being able to differentiate clearly between intrapersonal and interpersonal emotional process appears critical both conceptually and at the applied level when designing interventions. Further, the PEC seems to have a unique feature in considering the competence ‘using’. Indeed, the TEIQue global score displayed correlations and large effect sizes on all PEC factors and subscales, besides the PEC subscales “using one’s emotions” and “using others’ emotions”. However, the PEC subscale “using others’ emotions” indicated a large correlation with the TEIQue subscale “emotion management (others)”, and the PEC subscale “using one’s emotions” does not show any

correlation with large effect size with any TEIQue subscales. This finding points towards a unique characteristic of the PEC concerning its ability to measure the competence “using emotions” for both self and others, which the TEIQue does not address. This has both theoretical and applied consequences, given using one’s and others’ emotions is critical to make the most adaptive decisions and realize the most adaptive actions (Brasseur et al., 2013).

Limitations

Our study had some strengths (e.g., large sample size), but had also some limitations. For example, the sample comprised only students, and therefore results can’t be generalized to different populations. Future research should therefore investigate the convergent validity between the PEC and the TEIQue in other samples, as well as in other cultures. In addition, history of any psychiatric diagnosis or medicine use related to emotional dispositions was not controlled for. Moreover, some Cronbach’s α of the TEIQue subscales are just below the acceptable threshold of .70: emotion regulation (.68), emotion perception (.69), emotion management (.69), adaptability (.69) and assertiveness (.66), which suggests caution while interpreting the findings related to these subscales.

Conclusion

To further compare the validity of the two questionnaires, future research should test the PEC and the TEIQue concurrently in terms of outcomes, criterion validity, and relationships with ability measures of EI/EC, for example in the same vein as Freudenthaler and Neubauer (2005), who tested the convergent and discriminant validities of intra- and interpersonal emotional abilities with relevant performance measures. Further, the question of adapting the questionnaires to specific samples / areas of applications appears relevant, like it was done with the PEC for cancer patients (Baudry et al., 2020). In addition, the effort in determining the best way to assess EI/EC at the trait level appears worthwhile, given its importance in many domains. Noteworthy, a recent finding (Mikolajczak & Van Belleghem, 2017) showed

that every 1% increase in intrapersonal EC, as measured with the PEC, was found to correspond to 1% decrease in healthcare expenditure. Specifically, further investigation of EI/EC with a clear distinction between intrapersonal and interpersonal EI/EC appears important for addiction research. For example, to determine their implication and impact on different kinds of addictions, such as smoking, alcohol use, illicit drug use (Kun & Demetrovics, 2010), or addiction focusing on technology (Gugliandolo et al., 2019), such as addictions related to internet behaviours (Arrivillaga et al., 2020; Hsieh et al., 2018; Sechi et al., 2020; Wang & Zhang, 2020), and smartphone use (Arrivillaga et al., 2020; Busch & McCarthy, 2021; Mascia et al., 2020). Finally, clarifying the role of intra- and interpersonal EC would also help to design more specific interventions (Hodzic et al., 2017; Schütz et al., 2020), and promote healthy emotional growth of individuals, protecting against addictions as suggested by many researchers in this domain (Arrivillaga et al., 2020; Busch & McCarthy, 2021; Gugliandolo et al., 2019; Kun & Demetrovics, 2010; Mascia et al., 2020).

Table 1
TEIQue subscales and their definitions (Petrides, 2009)

Factors	Subscales	<i>High Scorers Perceive Themselves as . . .</i>
Well-Being	Self-esteem	Successful and self-confident
	Trait happiness	Cheerful and satisfied with their lives
	Trait happiness	Confident and likely to “look on the bright side” of life
Self-Control	Emotion regulation	Capable of controlling their emotions
	Stress management	Capable of withstanding pressure and regulating stress
	Impulsiveness (low)	Reflective and less likely to give in to their urges
Emotionality	Emotion perception (self and others)	Clear about their own and other people’s feelings
	Emotion expression	Capable of communicating their feelings to others
	Relationship skills	Capable of having fulfilling personal relationships
	Empathy	Capable of taking someone else’s perspective
Sociability	Social competence	Accomplished networkers with excellent social skills
	Emotion management (others)	Capable of influencing other people’s feelings
	Assertiveness	Forthright, frank, and willing to stand up for their rights
<i>These subscales do not belong to any particular factor and are directly included in the total score</i>	Adaptability	Flexible and willing to adapt to new conditions
	Self-Motivation	Driven and unlikely to give up in the face of adversity

Table 2

Profile of Emotional Competences subscales and their definitions (Brasseur et al., 2013)

Emotional Competence	Definition
Identification (own and others)	being able to perceive an emotion when it appears and identify it
Expression (own and others)	being able to express emotions in a socially accepted manner
Understanding (own and others)	being able to understand the causes and consequences of emotions, and to distinguish triggering factors from causes
Regulation (own and others)	being able to regulate stress or emotions when they are not appropriate to the context
Use (own and others)	being able to use emotions to improve reflection, decisions and actions

Table 3

Hypothesized significant correlations with large effect sizes

PEC Subscales	TEIQue Subscales
Identification (own)	Emotion perception (self and others)
Identification (others)	Emotion perception (self and others), Empathy, Relationship skills
Understanding (own)	Emotion perception (self and others)
Understanding (others)	Emotion perception (self and others), Empathy, Relationship skills
Expressing (own)	Emotion expression
Expressing (others)	Relationship skills
Regulation (own)	Emotion regulation, Stress management
Regulation (others)	Emotion management (others), Relationship skills
Use (own)	None
Use (others)	Emotion management (others), Relationship skills
PEC Factors and Global Score	TEIQue Factors and Global Score
Intrapersonal EC	Well-being, Self-control, Emotionality, TEIQue Global
Interpersonal EC	Emotionality, Sociability, TEIQue Global
Global EC	Well-being, Self-control, Emotionality, Sociability, TEIQue Global

Notes: TEIQue: Trait Emotional Intelligence Questionnaire; PEC: Profile of Emotional Competences; EC: Emotional Competences
