For Peer Review

Abstract

The study used a mixed-methods approach to examine how the presence of coaches influenced male academy rugby league players' performance during physical performance testing. Fifteen male rugby players completed two trials of 20 m sprint, countermovement jump and prone Yo-Yo test; one with only the lead researcher present and a second where the lead researcher conducted the battery with both the club's lead S&C coach, academy manager, and the first team assistant and head coach present. Players and coaches then completed one-to-one semi-structured interviews to explore their beliefs, attitudes and opinions towards physical performance testing. In all tests, the players' performance was better when the coaches were present compared to when this was conducted by the sport scientist alone. Interviews revealed performance testing was used by coaches to exercise their power over players to socialise them into a desired culture. Players' own power was evident through additional effort during testing when coaches were present. **Practitioners should ensure consistency in the presence of significant observers during performance testing of male rugby players to minimise their influence on test outcome.**

Key words: Fitness, monitoring, observer, power, habitus

Introduction

Team sport athletes require well-developed physical qualities to tolerate the demands of training and match-play¹⁻³. Such qualities include speed, strength, power, agility (or change of direction) and intermittent running capacity, as well as possessing the appropriate technical, tactical, psychological and social attributes for success. The assessment of physical qualities is routine practice within team sports, and enables sport scientists, strength and conditioning coaches and skills coaches to assess the development of players over time⁴⁻⁶, quantify the effectiveness of training interventions^{7,8} and reduce the risk of injury⁹.

The assessment of such qualities are often practised by the strength and conditioning (S&C) coaches, who have a vested interest in the results, with a positive change in performance indicative of a successful training programme. However, it is often the case that all those involved in the player's development as they progress from youth to professional status (i.e. coach, peers, owner, manager), also have an interest. Furthermore, the use of sport scientists from outside of the professional club, who might collect these data as part of research or wider talent development profiling on behalf of the sport's governing body, increases the surveillance network beyond the central locality of that squad (i.e. Academy)¹⁰. Nonetheless, the collection of such data tends to be perceived as positive by the players and staff¹¹, allowing the club to collect constant and normalised data creating a personalised profile that is then used to inform training, recovery or medical treatments¹². For the players, partaking in performance testing is believed necessary to attain success, and is potentially a mechanism through which they can distinguish individual excellence and demonstrate adherence to 'professional' ideals^{10,11,13}. The ability to manipulate the environment in which players complete performance testing is likely to alter their behaviour¹⁴. For example, if players feel that performance testing

1
2
3 is a suitable opportunity to display superiority over their peers, the presence of a coach, who
4 has the ability to select or deselect players into the senior squad, might, to some degree, alter
5 the players' approach and effort. Several researchers have also highlighted the influence of
6 others' (e.g. coaches) presence during training ¹⁵⁻¹⁹, suggesting this can reduce effort
7 perception, increase exercise adherence, intensity, motivation, and **improve** the adaptive
8 response. While the anthropometric and physical qualities of rugby league players has received
9 considerable interest, few, if any, studies report who was present during these assessments or
10 the attitude of the players and coaches to these practices ^{10,12}. Such insight might well be
11 important when interpreting any change in performance ¹⁵.

12
13
14
15
16
17
18
19
20
21
22
23
24
25
26 Whilst performance testing is common practice, little is currently known about the players' and
27 coaches' views towards these practices as well as their purpose and how this might vary in
28 accordance to the coaches' role. Furthermore, how the data collected is used throughout the
29 club by players, coaches and other members of staff is of particular interest given they are
30 likely to have different uses for this data ²⁰. McCormack and colleagues' observations revealed
31 the multi-dimensional use of objective physical testing beyond its intended use to complement
32 other subjective assessments (e.g. tactical, technical) that inform athlete preparation, selection,
33 standardisation and player motivation ^{20,21}. Jones et al.¹² also noted the head coach might use
34 particular variables to ensure players were meeting her/his expectation and as a form of
35 disciplinary power. In contrast, they found that the performance analysts and S&C coaches
36 used the data to monitor training load in an attempt to minimise injury risk. A thorough
37 understanding of the views and purpose of performance testing will help **practitioners** to
38 understand the various challenges of appropriately implementing such tests. Ultimately, this
39 could improve the application of performance testing and promote effective athlete
40 development.

1
2
3
4
5
6 The aim of this study was to use a mixed-methods approach to investigate if, and to what extent,
7
8 the coaches' presence influenced performance during a standardised testing battery for the
9
10 assessment of physical qualities. A secondary aim was to explore the opinions of players and
11
12 coaches towards performance testing within a professional academy rugby league
13
14 environment, drawing upon the figurational sociological concepts of habitus, power balances
15
16 and unintended consequences. It was hypothesised that the coach being present during testing
17
18 would **positively** impact upon on players' performance through the interaction of power
19
20 between coach and player. It is also possible that the opinions players held towards testing
21
22 would influence their performance.
23
24
25
26
27

28 **Methods**

29 **Participants and design**

30
31 All participants (players $n = 15$, coaches $n = 5$) were, at the time of the study, registered to a
32
33 professional rugby league club with data collected during the preseason training period for the
34
35 upcoming competitive season. All **participants** provided written consent to participate and the
36
37 study was approved by the authors' relevant research ethics committee (1372/17/ND/SES).
38
39
40
41
42
43

44
45 In the first stage of this study, 15 male **players (stature: 178.9 ± 6.1 cm; body mass: 85.9 ± 10.2**
46
47 **kg)** participated in the physical performance testing and deemed themselves to be free from
48
49 injury, which was confirmed by the club's medical team. **The required sample to detect a**
50
51 **positive impact of the coaches' presence was derived based on the data presented by Dobbin**
52
53 **et al. ²². The standardised mean difference (SMD) that ranged from 0.45 to 0.75 were inserted**
54
55 **into G*Power ²³ with α at 0.05 and β at 0.80. The required sample for 20 m sprint time,**
56
57 **countermovement jump (CMJ) and prone Yo-Yo Intermittent Recovery Test level 1 (prone**
58
59 **60**

1
2
3 Yo-Yo IR1) was 13, 14 and 32, respectively. However, as we only had access to 15 players,
4 we acknowledge a lower than desired statistical power for the Yo-Yo IR1 test ($\beta = \sim 50$) and
5 the probability of any effect for this outcome should be interpreted with caution. To support
6 interpretation, we have also reported the SMD and 95%CI to indicate the magnitude of the
7 difference and precision of the estimate. Participants were required to abstain from
8 performance-enhancing supplements (e.g., caffeine) and not to have completed any club-based
9 or leisure-time activity of high intensity in the 2 and 24 hours before testing, respectively. The
10 players completed two trials of tests (20 m sprint, CMJ and prone YoYo IR1) selected from
11 the Rugby Football League profiling testing battery²²; one with only the lead researcher present
12 and a second where the lead researcher conducted the battery with both the club's lead S&C
13 coach, academy manager, and the first team assistant and head coach present. Coaches did not
14 offer any verbal encouragement or motivation to participants, simply standing proximal to the
15 testing and within view of all participants for the duration of all tests. Trial order was not
16 randomised because of the inability to blind participants to the trial conditions. However, all
17 participants were habituated to the physical performance testing procedures having completed
18 the tests several times before as part of routine monitoring at the club. Both trials were
19 conducted 14 days apart in an indoor training facility (Trial 1 = temperature: 6°C, humidity:
20 89%, pbar: 1001 mbar; Trial 2 = tempearture: 4°C, humidity: 82%, pbar: 1012 mbar) on an
21 artificial grass surface.

47
48

49 In the second part of the study, approximately one week after the testing, 10 of the players who
50 had taken part in the trials and 5 coaches completed one-to-one semi-structured interviews with
51 a single researcher experienced in qualitative research methods. Within qualitative research,
52 sample sizes are determined by the richness of data which is collected, as opposed to a specific
53 number of participants^{24,25}. Therefore, alongside the limitations imposed by having access to
54
55
56
57
58
59
60

1
2
3 only those players and coaches within the one club, a pragmatic approach was taken to
4 determining the number of interview participants required, with the researcher halting data
5 collection once sufficient data had been collected to provide a rich exploration of the research
6 topic ²⁶. This allowed for the detailed exploration of the players' and coaches' beliefs, attitudes
7 and opinions towards physical performance testing for the assessment of anthropometric and
8 physical qualities. For the players, a second part of the interview also focused on their
9 perceptions towards their performance during the physical performance testing in trial 1 and 2.

19
20

21 The use of quantitative and qualitative methods in conjunction can be problematic due to the
22 differing philosophical assumptions of each approach. Quantitative methods are underpinned
23 by positivism, the belief that reality is singular and that its 'true' nature can be known by
24 researchers maintaining objectivity ²⁷. Meanwhile, qualitative methods are often underpinned
25 by interpretivism, the belief that realities are multiple and created through the individual's
26 subjective interpretation, therefore a 'truth' of reality cannot be known ²⁷. To bridge this
27 philosophical divide, a realist approach was taken, whereby reality is viewed as singular and
28 external but is influenced by an individual's subjective interpretation ^{28,29}. Therefore, this
29 paper sought to establish whether, and why, observer presence impacted performance during
30 the standardised testing battery whilst still assuming that this knowledge may be fallible and
31 is not a definitive 'truth' ²⁸.

49 **Procedures**

50
51 Stretch stature was measured using a portable stadiometer (Seca, Leicester Height Measure,
52 Hamburg, Germany) to the nearest 0.1 cm, and body mass (Seca, 813, Hamburg, Germany) to
53 the nearest 0.1 kg.
54
55
56
57
58
59
60

1
2
3 Participants completed a thorough warm-up based on the RAMP principles. Initially activities
4 that increased heart rate, muscle, and blood temperature (e.g., jogging) were performed before
5
6 activation (e.g., overhead lunge) and mobilisation (e.g., spinal extension). Finally, participants
7
8 completed a series of activities (e.g., squat jumps) to potentiate the muscle, and concluded with
9
10 several accelerations (50-100% effort), sprints (75 to 100% effort) and decelerations (100%
11
12 effort). A period of 5 minutes passive recovery was provided before the initial assessment of
13
14 sprint performance.
15
16
17
18
19
20

21 Sprint performance was measured using electronic timing gates (Brower, Speedtrap 2, Brower,
22
23 Utah, USA) positioned at 0 and 20 m, 150 cm apart and at the height of 90 cm. Participants
24
25 began each sprint from a two-point athletic stance 30 cm behind the start line. Two maximal
26
27 20 m sprints were recorded to the nearest 0.01 s with two minutes between each attempt and
28
29 the best 20 m sprint time was used for analysis possessing a CV of 3.6% ²².
30
31
32
33

34
35 Participants completed two countermovement jumps with 2-minutes passive recovery between
36
37 each attempt. Participants placed their hands on their hips and started upright before flexing at
38
39 the knee to a self-selected depth and extending up for maximal height, keeping their legs
40
41 straight throughout. Jumps that did not meet the criteria were not recorded, and participants
42
43 were asked to complete an additional jump. Jump height was recorded using a jump mat (Just
44
45 Jump System, Probotics, Huntsville, Alabama, USA) and corrected for accuracy³⁰ before peak
46
47 height was used for analysis, with a CV of 5.9% ²².
48
49
50
51

52
53 The prone Yo-Yo IR1 required participants to start each 40 m shuttle in a prone position with
54
55 their head behind the start line, legs straight and chest in contact with the ground. Shuttle speed
56
57 was dictated by an audio signal commencing at 10 km·h⁻¹ and increasing 0.5 km·h⁻¹
58
59
60

1
2
3 approximately every 60 s to the point at which the participants could no longer maintain the
4 required running speed. The final distance achieved was recorded after the second failed
5 attempt to meet the start/finish line in the allocated time. The reliability (CV% = 9.9%)²² and
6 concurrent validity of this test have been reported ³.
7
8
9
10
11
12
13

14 Interviews

15
16 One-to-one semi-structured interviews were employed using an interview guide but also
17 allowing a considerable degree of flexibility during the interview process to explore new areas
18 that emerged throughout the process. Each interview was recorded using a dictaphone and
19 transcribed *verbatim*. Interviews were used to attempt to “generate data which gives authentic
20 insights into peoples’ experiences”.²⁶ Interviews explored the experiences and views of the
21 players and coaches with regards to the physical performance tests. ²⁸
22
23
24
25
26
27
28
29
30
31
32

33 Statistical analysis

34
35 Descriptive statistics for the physical performance tests were presented as the mean ± standard
36 deviation (SD). The Shapiro-Wilk test was used to assess assumptions of normality, **with all**
37 **data meeting this assumption ($p = 0.309$ to 0.887)**. Separate paired sample *t*-tests were used to
38 determine differences ($p < 0.05$) in performance between trials with and without coach
39 presence. Standardised mean differences (SMD) with 95% confidence intervals were also
40 calculated using the difference in the means over the pooled standard deviation. SMD
41 thresholds were: 0.0 – 0.2, trivial; 0.2 - 0.6, small; 0.6 – 1.2, moderate; 1.2 – 2.0, large; >2.0,
42 very large. All statistical analysis was performed using SPSS (IBM SPSS Statistics for
43 Windows, Version 25.0, Armonk, NY, USA).

Thematic Analysis

Consistent with the philosophical assumptions of the study, a realist thematic analysis approach²⁸ was used to analyse interview data. From this analysis, four themes were identified: 1) The perceived value of physical performance testing; 2) Coaches' use of power to promote hard-work and determination; 3) Players' use of power to achieve career progression; and 4) Players respond differently to observer presence.

Results

Analyses revealed players were $-1.2 \pm 1.1\%$ (mean \pm 95% CI) faster during the 20 m sprint with (3.03 ± 0.08 s) compared to without (3.07 ± 0.10 s) the coaches present ($p = 0.035$, SMD \pm 95% CI: -0.31 ± 0.28). Players' CMJ jump height was $4.7 \pm 3.4\%$ higher with (42.0 ± 5.3 cm) compared to without (40.2 ± 6.0 cm) the coaches ($p = 0.006$, SMD \pm 95% CI: 0.27 ± 0.19). Finally, the players' prone Yo-Yo distance increased by $7.2 \pm 5.2\%$ (979 ± 223 cf. 1040 ± 186 m; $p = 0.015$, SMD \pm 95% CI: 0.28 ± 0.19) when coaches were present. Mean and individual values are shown in Figure 1.

***** Insert Figure 1 about here *****

Discussion

For the first time, we report the influence of coaches' presence on the outcomes of physical performance testing conducted by a sport scientist on professional team sport athletes. In all tests the athletes' performance was improved when the coaches were present compared to when this was conducted by the sport scientist alone. Further data gathered from interviews build upon these quantitative findings by providing insight into the perceptions of players and coaching staff towards performance testing, alongside highlighting potential explanations for

1
2
3 changes in player performance in the presence of observers. Within this discussion, the four
4 themes that were developed from these data are explored and used to suggest explanations for
5 these changes in performance.
6
7
8
9

10 11 12 *The perceived value of physical performance testing*

13
14 Primarily, head coaches placed considerable emphasis on these tests and viewed them as an
15 important barometer of a player's ability and felt that they helped to inform "a good recognition
16 of what the strengths and weaknesses are of each individual" (Head Academy Coach). In fact,
17 performance testing was held in such high regard by head coaches that it impacted on team
18 selection. Jones et al.¹² similarly found that coaches used Global Positioning System (GPS)
19 data on high-speed running to ascertain if players were training at an intensity that reflected
20 match play and would not select those who did not. In the present study, the Head of
21 Performance was questioned about whether testing impacted the head coach's team selection
22 and stated:
23
24
25
26
27
28
29
30
31
32
33

34
35 I have seen it impact on selection before and heard a lot about it impacting on
36 selection before. Yeah, lads not meeting their markers and it impacts on selection,
37 and at some clubs, it impacts when they have to return from an off season. If they
38 come back and meet certain markers then they will get some time off, if they meet
39 them again, they might get some more time off. So yeah, it impacts on selection
40 but also when they come back.
41
42
43
44
45
46
47
48
49
50

51
52 Ultimately, the use of testing by head coaches to shape team selection might be explained by
53 the belief that this would contribute to a potential competitive advantage. For example, both
54 head coaches suggested that the nature of rugby league required players who were resilient and
55 strong-willed and testing gave them "an indication of where players are mentally" (Academy
56
57
58
59
60

1
2
3 Head Coach). Additionally, testing informed training to improve players' physical
4 performance. For example, the Head Coach stated, "we can get better... by implementing
5 certain strength techniques in the gym and certain aspects of our training are designed around
6 testing, you know, to get stronger, to get faster" and that it was important to "implement [the
7 results] and get better and better and better each week, each month, each year continuously".
8 Also, testing informed the tactics employed by head coaches, with the Academy Head Coach
9 stating "it enables me to identify some positional specific stuff. So, for instance if I have got
10 halves and they are coming up on the sprint tests constantly slow, I might alter the way I play
11 the game".
12
13
14
15
16
17
18
19
20
21
22
23
24
25

26 However, for other members of coaching staff, testing was considered less useful, and they
27 placed less value on it. For example, Assistant Coach A felt that performance testing was
28 "probably not really too relevant to my role...I am probably looking at the smaller picture
29 stuff". These views were shared by Assistant Coach B: "I have got more things to worry about,
30 I let the head coach worry about that". These observations corroborate those reported
31 previously that the support around, and selection of, players adopts a multidimensional
32 approach of which physical performance testing is only part of the process ^{20,21}. Meanwhile,
33 players often stated that they simply did not like testing and viewed it as "one of those things
34 you got to do. It's part and parcel of it [being an academy rugby player]" (Player C). Some
35 players argued that performance testing was not important to them as it did not truly reflect
36 their rugby league ability and, therefore, they placed little value on it. However, some players
37 did feel that the testing informed whether their physical performance had improved. Also,
38 testing was viewed as valuable for players when coaching staff were present. Often, this value
39 came from the opportunity to impress the head coaches and "to stand out from the rest of the
40 team... [to] have the best opportunity to get into the first team" (Player D). Consequently,
41
42
43
44
45
46
47
48
49

1
2
3 players seem to value testing more in the presence of coaching staff primarily due to its
4
5 perceived use in team selection. According to figurational sociologists, individuals are
6
7 interdependent and form networks of social relations called ‘figurations’³¹. Within these
8
9 figurations, relations between interdependent individuals shape social culture, meanwhile this
10
11 social culture simultaneously shapes individuals’ socially constructed “personality make-up”
12
13 (p.59) known as habitus³¹. Therefore, by players valuing testing more in the coaching staff’s
14
15 presence it seems that players’ habituses were built around a desire to play the game itself and
16
17 progress into the first team.

21
22
23
24
25

26 *Coaches’ use of power to promote hard-work and determination*

27
28 The role of physical performance tests in rugby league is multifaceted²⁰. Whilst testing did
29
30 seem to inform training, our interview data suggest that these tests were frequently used by
31
32 coaches to exercise their power over players. This was primarily done by coaches surveilling
33
34 players during testing to assess their character. For coaches, testing was viewed as an
35
36 opportunity to identify athletes who were mentally resilient and “who can hang on the longest”
37
38 (Head Coach). This is summarised by the Head Academy Coach who stated:
39
40
41

42 it gives me an indication of where players are mentally... when we do two bouts
43
44 of testing close together like we did, I can see, I can recognise social loafing and
45
46 stuff like that and recognise people who want to improve and want to put it in and
47
48 realise what the testing is about, and other people who may have that attitude that
49
50 it’s not as important as the rugby side.
51
52
53
54
55

56 To this end, coaches appeared to make judgements on whether a player was of sufficient
57
58 standard to compete for the club based upon this testing, supported by the previous point
59
60

1
2
3 highlighting that team selection would be influenced by testing performance. Players who were
4 seen as showing ‘poor’ character during these tests were subsequently challenged by coaches
5 and viewed as not being at the required playing standard. For example, the Head Academy
6 Coach recalled saying to one of his players:
7
8
9
10
11

12 Do you think you are ever going to become a professional athlete if you don’t do what’s
13 required of you from all aspects of training? And that’s about all aspects of training we
14 require from you.
15
16
17
18
19
20

21 Fundamentally, the coaches placed such emphasis on testing as a tool to measure the players’
22 character with the aim of creating a culture within the club that promoted hard-work and
23 determination. This is encapsulated by Assistant Coach A who felt that testing was “for
24 building some mental toughness resilience for the journey”. Similarly, Assistant Coach B
25 stated:
26
27
28
29
30
31

32 You would want the players to hit as hard as they can with the coach there or not there.
33
34 I live in the real world; I know that some won’t, so what you are trying to do is put the
35 right people there in the club... to create the right culture
36
37
38
39
40
41

42 Power is constantly in flux and is balanced between interdependent humans within figurations
43 ³¹. In this instance, power appeared to be balanced towards coaches due to their ability to shape
44 team selection based upon testing performance. As coaches used testing to assess a player’s
45 character, it seems that they tried to use **this power** to encourage a social culture that promotes
46 hard-work and determination, which they hoped players would be socialised into and
47 internalise. This aligns with previous research, which suggests that surveillance techniques are
48 used by coaches to normalise athlete behaviour and shape athletes into the desired ‘type’ of
49 person ^{10–12}.
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6 *Players' use of power to achieve career progression*

7
8 Power balances between coaches and players provided an extra incentive for players to work
9
10 hard and show character, however, such additional effort was performative. Indeed, players'
11
12 performance improved, on average, for the sprint, jump and intermittent running tests by 1.2,
13
14 4.7 and 7.2%, respectively with the coaches present, compared to when tests were conducted
15
16 by the sport scientist alone. Furthermore, our interview data show that players would put in
17
18 additional effort in the presence of coaches to display a 'strong' character. For example, Player
19
20 C stated:
21
22

23
24
25
26 They [the coaching staff] want to see how mentally tough you are and how much
27
28 you dig in. Like, when you're bolloxed, they don't want you to just give up, you
29
30 know, like they want you to keep going and going and going until you can't go
31
32 anymore.
33
34

35
36
37
38 Meanwhile, Player G felt that "you have to push yourself to try and impress him [the head
39
40 coach]" and make sure "it *looks* like you are putting the effort in to do it". However, these
41
42 data, considered alongside the point that many players only saw value in testing when coaches
43
44 were present, suggest that this additional effort was performative. This highlights how power
45
46 was also balanced towards the players who seemingly chose whether they gave maximum
47
48 effort in testing. Additionally, this suggests that players did not internalise a 'hard-working'
49
50 habitus in respect to testing that the coaching staff desired. Rather, this reinforces the point that
51
52 players' habituses were built around progressing into the professional game and testing was
53
54 used as an opportunity to achieve this as they saw fit. Therefore, coaches attempting to exercise
55
56 their power and use testing to assess the character of players did not promote the hard-working
57
58
59
60

1
2
3 culture in the manner they had hoped. Instead, this caused players to exercise their own power
4 and merely perform differently in the presence of coaches during such tests, which further
5 highlights how power is in flux within the figuration. Taken together we suggest that when
6 using performance tests to appraise players' physical qualities as part of longitudinal
7 monitoring, practitioners should ensure consistency in the personnel observing the procedures.
8
9
10
11
12
13
14
15
16

17 *Players respond differently to observer presence*

18
19 Collective test performance with the coaches in attendance were statistically better ($p = 0.006$
20 to 0.035), albeit changes were small (SMD = 0.27 to 0.31) and within the reported trial to trial
21 error for these tests²². For example, the improvement in sprint performance was better than the
22 ~0.3% change reported in academy rugby league players after a pre-season training period³²,
23 but smaller than the 5.9% faster times observed in senior players after an 8-week resistance
24 training intervention³³. Likewise, the observed increases in CMJ and prone Yo-Yo between
25 trials were lower than changes reported in a similar group of academy rugby league players
26 after pre-season training (~10% and ~20%, respectively;³²). However, when the data are taken
27 on an individual basis, six of the fifteen players reported improvements in prone Yo-Yo
28 performance between 120 and 200 m when the coaches attended. Therefore, 40% of the players
29 made improvements in intermittent running performance that would be deemed beneficial
30 based on required change in running performance reported for this test²². Given the strong
31 associations between prone Yo-Yo distance and rugby league match running performance³,
32 and that a better prone Yo-Yo performance differentiates between playing standards³⁴, players
33 not providing a true maximal effort in the test means coaches would be misinformed when
34 using this data to inform training or team selection. The fewer number of players that showed
35 beneficial improvements in CMJ ($n = 2$) and sprint performance ($n = 1$) when the coach was in
36 attendance perhaps reflects the nature of the tests compared to the prone Yo-Yo test, suggesting
37

1
2
3 that players are more capable of replicating short duration, all-out tests and that these are less
4 susceptible to the influence of observers. Alternatively, these larger fluctuations in Yo-Yo test
5 performance under the presence of observers might be due to the emphasis participants placed
6 upon this test. Players reported that the Yo-Yo test was the hardest of the battery and that it
7 was viewed as “the big one” (Player A). As such, the players focussed upon this test and
8 directed their energy towards it. For example, Player I stated that “the Yo-Yo test is the hardest
9 because that’s like conditioning but the rest of them aren’t too bad”. Furthermore, players
10 implied that the Yo-Yo test specifically provided an opportunity for coaches to see which
11 players had good character, supporting the idea that such testing is viewed as a character test.
12 For instance, Player A was asked what they felt the coaches gained from being present at testing
13 and responded by saying: “Well, [to see] how people deal with it, right. When, say when the
14 Yo-Yo starts getting hard, yeah, how people react to it”. Indeed, coaches seemed to
15 purposefully attend some testing sessions to see how players would react, for example Assistant
16 Coach A stated:

17

If the head coach is present, it’s kind of like “oh shit” you know what I mean? To
give them a bit of .. “oh, the head coach is there we will work a bit harder”. So that
would be the purpose of why he would be there.

Consequently, this provided an opportunity for players to demonstrate their character and be
seen positively by coaches, which in turn appeared to significantly influence the effort players
gave during this specific test. This is highlighted by statements made by players such as “I tried
to do better because someone like him [the head coach] was there” (Player F) and “I think, as
a whole, all of us, like, try harder if you know what I mean? Because they were there watching,
so I think that had an impact on us” (Player D). However, for some participants this observer
influence had an adverse effect. For example, Player I displayed a reduction in Yo-Yo

1
2
3 performance with observers present and felt that there was an “added pressure”. Also, the Head
4 Academy Coach felt that they “noticed more tension really and that could have had a negative
5 effect on some of the testing results”. Therefore, it seems that the coaching staff sometimes
6 manipulate their power by observing testing with the intention of encouraging players to try
7 harder and improve their performance. However, through the interdependence of the players
8 and coaches, and the power balances between them, an unintended outcome occurred ³¹,
9 whereby performance improved for some players but worsened for others. Consequently, the
10 variability of individual performance in the presence of observers during these tests, especially
11 the Yo-Yo, severely undermines their validity. Our findings are the first to report such impact
12 of observer presence on performance testing.

Our study is not without limitations. Using a single club meant the player and coach recruitment was restricted to those employed by the organisation. Thus, the club’s and individual coaching philosophies will have influenced perceptions and attitudes of both players and coaches towards performance testing. Restriction to a finite number of players within the club means we acknowledge the potential overestimation of the population effect for the prone YoYo IR1. Albeit players and coaches were well familiarised with the testing, we were also unable to conduct the study using a randomised crossover design to limit any order effects. Future studies using larger sample sizes from a range of clubs, with a more truly experimental design are warranted.

51 *Conclusions*

52
53 Our findings show that athlete performance during a standardised testing battery for the
54 assessment of physical qualities generally improved when coaches were present. Performance
55 testing was mainly used by coaches to exercise their power-chances over players in the hope
56
57
58
59
60

1
2
3 of generating a social culture that promoted hard-work and dedication, which players would be
4 socialised into and adopt. Performance testing was used to assess the ‘character’ of the players
5 and decide if they were of sufficient standard to be at the club, which consequently informed
6 team selection. However, athletes exercised their own power by providing additional effort in
7 the presence of coaches exclusively. This reinforces the argument that their habitus was centred
8 around being selected for the team and progressing within the sport rather than around
9 persistent hard-work that the coaches tried to promote. The interdependence of coaches and
10 players, and the power balances between them, led to the unintended consequence of some
11 athletes’ performance worsening during this test. Ultimately, our findings challenge the
12 validity of such tests under the presence of coaches and encourage practitioners to strive for
13 consistency in observing staff members when conducting these procedures as part of
14 longitudinal monitoring.

Practical implications

34
35
36
37
38
39
40 Primarily, the findings of our study can help to inform coaches and practitioners of the
41 challenges of implementing performance testing appropriately. Whilst our findings suggest that
42 the presence of coach observers undermines the validity of various performance tests, this is
43 not to say that performance tests have no value in applied contexts. Instead, practitioners should
44 consider the presence of coaches during performance testing and be wary of the impact this
45 might have on the results of such tests. By doing so, the application of performance testing
46 might be improved and better promote effective athlete development. Ideally, there should be
47 consistency with the presence of observers during testing procedures to minimise this
48 influence, however we are aware that this is often beyond the control of the practitioner and
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 might not be feasible. Accordingly, further research that investigates the power relations
4
5 between practitioners and coaching staff, specifically related to the context of physical
6
7 performance testing, might provide insight into the complexities of ensuring such consistency
8
9 of observers. Finally, future research may benefit from investigating whether these findings are
10
11 applicable to senior athletes within the professional game, where the pressures and incentives
12
13 for players might differ to those of younger players.
