Most research on perfectionism in sport, dance, and exercise continues to examine the effects of dimensions of perfectionism separately. In this chapter, we describe this independent effects approach and revisit our previous review of research that has adopted it in sport, dance, and exercise. In doing so, we provide an updated account of the thoughts, emotions, and behaviours related to multidimensional perfectionism. In a further extension of our previous work, we also include a focus on the *total unique effect* of perfectionism. This is a new approach to examining the effects of multidimensional perfectionism and can be used to help determine whether, overall, perfectionism is adaptive, maladaptive, or neutral. Our updated review shows that research in this area continues to grow, most notably in sport. In addition, consistent with our previous review perfectionistic concerns and perfectionistic strivings continue to be associated with contrasting patterns of effects. In illustrating the use of total unique effects, we show for the first time that, overall, perfectionism is likely to be maladaptive in these domains, largely due to the relative influence of perfectionistic concerns.

Perfectionism in sport, dance, and exercise

As described in previous chapters in this book, there are several different multidimensional models of perfectionism that have been adopted in research in sport, dance, and exercise. Here, we follow the hierarchical model described in Chapter 1. Specifically, we consider the dimensions of perfectionism drawn from separate models to be indicative of two higher-order dimensions. Perfectionistic strivings capture “aspects of perfectionism associated with self-oriented striving for perfection and the setting of very high personal performance standards” (Gotwals et al., 2012, pp. 264). Perfectionistic concerns capture “aspects associated with concerns over making mistakes, fear of negative social evaluation, feelings of discrepancy between one’s expectations and performance, and negative reactions to imperfection” (Gotwals et al., 2012, pp. 264). When considering how these two broad

dimensions of perfectionism might manifest in sport, dance, and exercise, it might be apparent that they have the potential to have opposing effects. One might visualise this as a tug of war, with perfectionistic strivings pulling hard in one direction and perfectionistic concerns pulling hard in the other.

The competing forces of perfectionistic strivings and concerns are often evident in the personal accounts of perfectionistic athletes. One recent illustrative example is provided from tennis in the case of Emma Raducanu. At the 2021 US Open, Raducanu, a self-identified perfectionist, became the first qualifier to win a coveted grand slam since the open era began in 1968. Both perfectionistic strivings and perfectionistic concerns appear to have been instrumental in her development and in shaping her experiences. When recounting her formative years, Raducanu (2022) has expressed the importance of her drive for exacting and perfectionistic standards for her success. However, she also cited the strain of an inability to accept even minor mistakes, how it could be "really self-destructive," and recognised the need to try to let go of her unrealistic pursuit of perfection.

Capturing the independent effects of perfectionistic strivings and concerns

One of the most common approaches to examining perfectionistic behaviours in sport, dance, and exercise, is to focus on the effects of perfectionistic strivings and perfectionistic concerns separately. This approach is based firmly on the notion that perfectionism is multidimensional and that the two main dimensions ought to be differentiated. The differentiation between the two dimensions is important because perfectionistic strivings and perfectionistic concerns have long been shown to have a contrasting pattern of relationships with various criterion variables (Stoeber & Otto, 2006). Consequently, research that considers the two dimensions separately helps address this issue and, in turn, provides insight into the opposing effects of dimensions of perfectionism (Stoeber, 2012). This approach contrasts to

other approaches described later in this book that attempt to examine different combinations or interactive effects of perfectionistic strivings and perfectionistic concerns (see Chapters 5 and 6 for discussion of the tripartite model and 2 × 2 model of perfectionism, respectively).

The first approach to examining the effects of perfectionistic strivings and perfectionistic concerns separately is to do so in a manner that ensures each dimension is conceptually 'intact' and statistically unaltered. That is, any relationship between the two dimensions is not statistically controlled or taken into account. Here, we are referring to an approach that examines the linear relationship between perfectionistic strivings or perfectionistic concerns and some other criterion variable. This approach can be observed in research examining perfectionism in sport, dance, and exercise (and research more widely) when using bivariate correlations (e.g., Madigan et al., 2016) or error-free correlations among latent factors in structural equation modelling (e.g., Curran, 2018).

A second approach to examining the effects of perfectionistic strivings and perfectionistic concerns separately focuses on their unique effects. This entails examination of the effects of perfectionistic strivings and perfectionistic concerns after statistically controlling for their relationship. This is achieved via statistical partialling. Statistical partialling involves holding the effects of one variable constant while examining the effects of another (Lynam, Hoyle, & Newman, 2006). Partialling can take place among predictor variables only (creating semi-partial correlations) or among predictor variables and the criterion variable (creating partial correlations). In the case of the former, new residualised predictor variables are created and the criterion variable is unchanged. In the case of the latter, new residualised predictor variables and a new residualised criterion variable are created. Partialling can be observed in research examining perfectionism in sport, dance, and exercise (and research more widely) when using multiple regression (regression coefficients;

e.g., Květon et al., 2021) and structural equation modelling (path coefficients; e.g., Wang et al., 2020).

The new dimensions of perfectionism that are created following partialling have previously been referred to as “pure” perfectionistic strivings and “pure” perfectionistic concerns (Hill, 2014; Hill & Curran, 2016; Stoeber, 2014). These terms were used to portray the notion that perfectionistic strivings and perfectionistic concerns are not “contaminated” by the other (Stoeber & Otto, 2006). We now consider the terms “residual perfectionistic strivings” and “residual perfectionistic concerns” to be a more accurate and less misleading labels. This is because the “pure” label suggests that following partialling the two dimensions are unrelated to each other when, in fact, it is the residualized variable and the unresidualized opposite that are unrelated (e.g., residual perfectionistic strivings and perfectionistic concerns) (Hill et al., 2018). The term “pure” is also used in the 2 × 2 model of perfectionism when labelling subtypes of perfectionism (see Chapter 6) so confusion can be avoided in that regard, too.

Partialling is illustrated in Figure 4.1 which depicts the unpartialled, partialled, and semi-partialled relationship between perfectionistic strivings and perfectionistic concerns with a criterion variable. The conceptual ramifications of the creation of residual perfectionistic strivings and residual perfectionistic concerns are discussed later. For now, the reader can simply note that perfectionistic strivings and perfectionistic concerns are altered following statistical partialling and, therefore, warrant new labels.

[Figure 4.1 here]

Partialling perfectionistic strivings and perfectionistic concerns is warranted for several reasons. Firstly, perfectionistic strivings and perfectionistic concerns typically display a positive and moderate relationship with each other. Consequently, if one is interested in whether a particular relationship is due to the unique features of perfectionistic strivings or the unique features of perfectionistic concerns, partialling is necessary. Secondly, perfectionistic strivings and perfectionistic concerns often display opposing relationships with the same criterion variable (e.g., depressive symptoms; Smith et al., 2018). Therefore, examining their unique effects provides a clearer reflection of these divergent relationships. Thirdly, there is evidence that perfectionistic strivings and perfectionistic concerns supress each other and this is especially pronounced for perfectionistic strivings. That is, before partialling, perfectionistic strivings can often appear ambiguous in terms of its correlates but is more clearly adaptive after partialling. Due to these issues, there is value in partialling perfectionistic strivings and perfectionistic concerns and to studying residual perfectionistic strivings and residual perfectionistic concerns (see Hill, 2014, for consideration of some of the pitfalls).

A review of research examining perfectionistic strivings and concerns

A large amount of research has examined perfectionistic strivings and perfectionistic concerns separately. Outside of sport, dance, and exercise, Stoeber and Otto (2006) conducted the first substantial review of perfectionism research and adopted this approach. In terms of perfectionistic strivings and concerns, the first aim of their review was to examine whether the two could be differentiated based on their associations with positive and negative characteristics. The second aim was to investigate whether perfectionistic strivings might be considered positive due to its association with positive characteristics. Studies were considered for inclusion if perfectionistic strivings and perfectionistic concerns had been measured using established multidimensional instruments. This resulted in the inclusion of

thirty-five studies published between 1993 and 2005. The samples in these studies were drawn from undergraduate students, outpatients, and academically gifted children. Of these studies, fifteen examined the correlates of perfectionistic strivings and concerns (the other studies used group-based approaches). To address the second aim, the fifteen studies were graded in terms of the support provided for the notion that perfectionistic strivings are positive or adaptive (viz. positive evidence, negative evidence, mixed evidence, and inconclusive/null findings).

Across the fifteen studies there was a clear distinction between perfectionistic strivings and perfectionistic concerns. The pattern of findings for perfectionistic concerns was straightforward in that they were positively related to negative characteristics (e.g., neuroticism, depression, and avoidant coping) and either unrelated or inversely related to positive characteristics (e.g., self-esteem, positive affect, and social support). However, for perfectionistic strivings, the pattern of findings was more equivocal. That is, in six of the fifteen studies, perfectionistic strivings were found to be positively related to positive characteristics only (e.g., conscientiousness, positive affect, and satisfaction with life). These studies provided positive evidence. In four studies, perfectionistic strivings were related to negative characteristics only (e.g., self-blame, depression, and anxiety). These studies were taken as negative evidence. A further four studies indicated that perfectionistic strivings were related to both positive and negative characteristics (e.g., conscientiousness and neuroticism). These studies were taken as mixed evidence. There was one inconclusive, null finding, where perfectionistic strivings were found to be unrelated to a positive characteristic (self-esteem).

While this initial categorisation of findings provided useful insight into perfectionistic strivings and perfectionistic concerns, Stoeber and Otto (2006) noted and then addressed a key limitation. Specifically, they identified that findings from the fifteen correlational studies seemed to relate to how strongly perfectionistic strivings and perfectionistic concerns were

correlated, with high correlations ($.45 \leq rs \leq .70$) tending to result in negative evidence or mixed evidence. In accord, the studies were re-examined using partial correlations. The purpose was to identify any change in findings for perfectionistic strivings when the overlap with perfectionistic concerns was controlled for (i.e., when examining residual perfectionistic strivings). Based on partial correlations, ten of the fifteen studies (versus six of fifteen previously) could now be categorised as positive evidence. Of the remaining five studies, no studies were categorised as negative evidence, three provided mixed evidence, and two had inconclusive/null findings. Therefore, controlling for the relationship between perfectionistic strivings and concerns helped to clarify the distinction between the two dimensions, as well as the associations of perfectionistic strivings, in the form of residual perfectionistic strivings.

Building on this work and others (e.g., Stoeber, 2011), Gotwals et al. (2012) conducted the first systematic review of perfectionistic strivings and perfectionistic concerns in sport. The particular focus of the review was on the nature of perfectionistic strivings and its associations with adaptive and maladaptive characteristics, processes, and outcomes. Studies were included if bivariate correlations between indicators of perfectionistic strivings and perfectionistic concerns were reported and at least one characteristic examined could be clearly identified as adaptive (e.g., positive affect, task orientation, and self-esteem) or maladaptive (e.g., negative affect, ego orientation, and symptoms of athlete burnout). This resulted in the inclusion of twenty-six research articles, reporting thirty-one studies, published between 1998 and 2010. Across the thirty-one studies, ninety-two bivariate and partial correlations with adaptive characteristics and one hundred nine bivariate and partial correlations with maladaptive characteristics were examined. These correlations were categorised in terms of support for the degree to which perfectionistic strivings, with perfectionistic concerns unpartialled and partialled, were associated with adaptive versus

maladaptive characteristics (viz. supportive evidence, contrary evidence, mixed evidence, and non-significant findings).

The findings of the review demonstrated a mixed profile for perfectionistic strivings when unpartialled from perfectionistic concerns. In terms of emotions, perfectionistic strivings were positively related to positive emotional experiences, including positive affect, self-confidence, and self-esteem (e.g., Kaye et al., 2008; McArdle & Duda, 2008; Stoeber et al., 2007). They were also positively related to negative emotional experiences, including negative affect, anger, cognitive anxiety, and self-esteem instability (e.g., Dunn et al., 2006; Hall et al., 2009; Kaye et al., 2008). In terms of motivation, perfectionistic strivings were positively related to hope of success, mastery-approach goals, and a task orientation, but also fear of failure, mastery-avoidance goals, performance-avoidance goals, and an ego orientation (e.g., Appleton et al., 2009; Stoeber & Becker, 2008; Stoeber, Stoll et al., 2009). In addition, they were positively related to intrinsic motivation, identified regulation, introjected regulation, and external regulation (McArdle & Duda, 2004). Finally, in terms of performance, perfectionistic strivings were positively related with performance in training and performance in competition (Stoeber, Uphill et al., 2009; Stoll et al., 2008).

The profile of residual perfectionistic strivings mirrored the profile of perfectionistic strivings in relation to performance. However, a more adaptive profile was evident for residual perfectionistic strivings in relation to emotions and motivation. When residual perfectionistic strivings were examined, the relationships with positive emotions became stronger (e.g., Kaye et al., 2008; McArdle & Duda, 2008; Stoeber et al., 2007); the relationships with negative affect, anger, and self-esteem instability became non-significant (e.g., Dunn et al., 2006; Hall et al., 2009; Kaye et al., 2008); and residual perfectionistic strivings displayed an inverse relationship with cognitive and somatic anxiety (e.g., Stoeber et al., 2007). Regarding motivation, the relationships between residual perfectionistic

strivings and adaptive motivation were comparable or stronger (e.g., Appleton et al., 2009; McArdle & Duda, 2004; Stoeber et al., 2008). Specifically, the relationship with fear of failure became inverse (e.g., Stoeber & Becker, 2008); the positive relationships with ego orientation and external regulation were smaller (e.g., Dunn et al., 2002; McArdle & Duda, 2004); and the relationships with mastery-avoidance goals, performance-avoidance goals, and introjected regulation became non-significant (e.g., McArdle & Duda, 2004; Stoeber, Stoll et al., 2009).

The growing body of studies available by the mid-2010s enabled the first meta-analysis of multidimensional perfectionism in sport by Hill et al. (2018). The aim of this meta-analytical review was to update and extend previous reviews by calculating effect sizes across studies for the unpartialled and partialled relationships that perfectionistic strivings and perfectionistic concerns shared with motivation, emotion/well-being, and performance. Hill et al. (2018) included criterion variables providing there were at least three studies to calculate effects and, unlike previous reviews where only clearly adaptive or maladaptive criterion variables were examined, also included criterion variables that were neither clearly adaptive nor maladaptive (e.g., performance approach goals). They were also able to use the meta-analytical approach to assess potential moderators of the effects of perfectionism (gender, age, sport type and the instrument/subscale used to measure perfectionism). The meta-analysis comprised 52 studies and 361 effect sizes.

Consistent with Gotwals et al. (2012), unpartialled perfectionistic strivings displayed a mixed profile of motivation, emotion/well-being and performance. Specifically, Hill et al. (2018) found that perfectionistic strivings shared negligible (task-involving coach climate) -to-medium (intrinsic motivation, mastery approach) positive relationships with adaptive motivation, small positive relationships with mastery avoidance and fear of failure, small-to-medium relationships with identified and introjected regulation, and a medium-to-large

positive relationship with performance approach goals. Further, perfectionistic strivings shared small positive relationships with self-esteem and self-confidence but also trait anxiety, cognitive anxiety and worry, small-to-medium positive relationships with positive affect and enjoyment, and a medium positive relationship with self-criticism. Perfectionistic strivings was unrelated to negative affect, rumination, depressive symptoms and satisfaction. It shared a small-to-medium positive relationship with athletic performance. In line with previous reviews, the profile of residual perfectionistic strivings was more adaptive in terms of motivation and emotion. For example, residual perfectionistic strivings was unrelated to fear of failure and shared a small negative relationship with cognitive anxiety. The relationship with athletic performance remained positive and small-to-medium.

Unpartialled perfectionistic concerns displayed a largely maladaptive profile of motivation and emotion/wellbeing. Specifically, perfectionistic concerns was unrelated to intrinsic motivation, mastery approach goals, shared a small-to-medium positive relationship with ego orientation, medium positive relationships with performance approach goals, performance avoidance goals, mastery avoidance goals and amotivation, a medium-to-large positive relationship with ego-involving coach climate, introjected regulation, external regulation, and fear of failure, and a small negative relationship with task-involving coach climate. Perfectionistic concerns also shared a small-to-medium positive relationship with negative affect, medium positive relationships with trait anxiety, cognitive anxiety, self-criticism, rumination, and depressive symptoms, small-to-medium negative relationships with self-confidence and satisfaction, a medium-to-large negative relationship with self-esteem, and was unrelated to positive affect, enjoyment and athletic performance. As expected, for some variables residual perfectionistic concerns displayed more maladaptive associations (e.g., a large positive relationship with cognitive anxiety, small negative relationship with intrinsic motivation). However, there were a small number of other instances where residual

perfectionistic concerns displayed a relatively less maladaptive profile (e.g., negligible relationship with ego orientation).

Some initial evidence of moderation by gender, age, sport type, and instrument were also found. However, these findings should be interpreted tentatively given they are based on a relatively small number of studies (Hill et al., 2018). For gender, the relationships found for predominantly female samples appeared to be typically more maladaptive than for predominantly male samples (e.g., perfectionistic strivings and negative affect). For age, the differences in the relationships for predominantly adult and adolescent samples were mixed with some relationships more adaptive for adolescents (e.g., perfectionistic strivings and perceived athletic ability) and others more maladaptive for adolescents (e.g., perfectionistic strivings and negative affect). For sport type, some relationships also differed in direction as well as magnitude and significance depending on team versus individual sport (e.g., the relationship between perfectionistic concerns and self-confidence was small, negative and significant for team sports but small, positive and non-significant for individual sports). Finally, for instrument, there was evidence that relationships differed depending on the specific subscales used to measure perfectionistic strivings and perfectionistic concerns. For example, the positive relationship between residual perfectionistic concerns and cognitive anxiety was small and significant when the concern over mistakes subscale was used but large and significant when negative reactions to imperfection was used.

Taken together, we now have an extensive body of knowledge documenting and reviewing the independent effects of perfectionistic strivings and perfectionistic concerns in sport. This work has highlighted perfectionistic concerns to be maladaptive in regards to emotion/wellbeing and motivation. By contrast, perfectionistic strivings are more complex and ambiguous, sharing a mixed pattern of relationships with the same criterion variables but seemingly more advantageous than perfectionistic concerns when it comes to performance.

Also, it is clear from the reviews to date that partialling matters. That is, when the variance between perfectionistic strivings and perfectionistic concerns and the relevant outcome is controlled, the magnitude and in some cases the direction of the relationships can change. Of particular note, while residual perfectionistic concerns are largely similar to perfectionistic concerns, residual perfectionistic strivings often appear much more adaptive than perfectionistic strivings.

An Updated Review of the Independent Effects of Perfectionism

For this current chapter, we have revisited and updated our original review of research that was presented in the first edition of this book. It is valuable to do so, first because since the first edition chapter, interest in perfectionism in sport, dance, and exercise appears to have grown considerably. We are now seeing studies examining perfectionism in these domains in academic journals and at scientific conferences much more frequently. Second, while the first meta-analytical review has also appeared since our last review, it focused only on sport, rather than dance and exercise. It has also been five years since the end of the search date in the Hill et al. (2018) meta-analyses. Therefore, for the benefit of researchers and practitioners, we are seeking to re-establish the state of knowledge and what is now known about the separate effects of perfectionism in these domains. Third, in repeating our review, we have been able to check and correct any previous errors when reporting the features of the studies, correlations and partial corrections.

In conducting the new review, we followed the same methodological approach to our original review. The review is based on an electronic search of PsycINFO, PsycARTICLES, and SPORTDiscus using the terms perfection* (for perfectionism, perfectionist) AND sport OR dance OR exercise) for peer-reviewed journal articles published in English [date of search: 23-06-2022]. The review spanned from January 1990 to July 2022. The search

produced *k* = 804 studies. After removing duplicates, and reviewing titles and abstracts for relevance this was reduced to *k* = 296. As in our previous search we excluded qualitative studies, unidimensional measures of perfectionism, or studies reporting only total scores, studies that used instruments with questionable validity, and those that did not include bivariate correlations. The final total was 156 studies.

[Table 4.1 here]

An obvious initial observation regarding the results of the review is the considerable increase in the number of studies since our first review. The number of studies included in the new review has doubled over a much shorter period (1990 to 2016 versus 2016 to 2022). Most research that has taken place since the first review has done so in a sport domain. Some of this research revisits existing relationships (e.g., burnout) and other research includes previously unexamined variables (e.g., attitudes towards doping). There is also a notable increase in focus on the athlete's social context and performance in newer studies. Of note, too, is that studies in dance and exercise have increased but to a lesser extent. New research in dance and exercise largely includes studies that have examined similar variables found in sport research such as burnout, goals and motives for participation, and psychological needs (e.g., Jowett et al., 2021; Molnar et al., 2021; Nordin-Bates et al., 2020). However, a distinctive focus on exercise dependence and eating pathology is a feature of emerging research in the exercise domain (e.g., Deck et al., 2021).

In regards to the findings of this new research, our updated review supports previous work by again highlighting divergence between perfectionistic strivings

(complex/ambiguous) and perfectionistic concerns (maladaptive). With reference to some of the new criterion variables, perfectionistic strivings, when unpartialled, shared a medium positive relationship with failure/evaluation worry, a small positive relationship with optimism in athletes (Dunn et al., 2020), small-to-medium positive relationships with dimensions of engagement in dancers (Jowett et al., 2021), and large positive relationships with the dark triad personality traits in exercisers (González-Hernández et al., 2021). As expected, residual perfectionistic strivings generally displayed a generally more adaptive profile (e.g., a non-significant relationship with failure/evaluation worry, and a medium positive relationship with optimism). By contrast, perfectionistic concerns, when unpartialled, shared a large positive relationship with failure/evaluation worry and a small negative relationship with optimism (Dunn et al., 2020), medium-to-large positive relationships with the dark triad (González-Hernández et al., 2021), and small negative relationships with engagement (Jowett et al., 2021). Residual perfectionistic concerns displayed a more maladaptive profile with some variables (e.g., small-to-medium negative relationships with engagement), but also a more adaptive profile with others (e.g., small-to-medium relationships with the dark triad).

New research also suggests similar patterns for perfectionistic strivings and perfectionistic concerns in relation to social interactions with coaches and parents. Unpartialled and residual perfectionistic strivings shared small positive correlations with the coach-athlete relationship (Martin et al., 2021) and parental conditional regard (Curran, 2018). By contrast, unpartialled and residual perfectionistic concerns shared non-significant correlations with the coach-athlete relationship, and large positive relationships with parental conditional regard (Curran, 2018). The picture for interactions with peers is less consistent. In the study by Grugan et al. (2019), perfectionistic strivings (unpartialled and residual) shared non-significant relationships with angry reactions towards teammates as well as antisocial

behaviour towards teammates and opponents. By contrast, perfectionistic concerns (unpartialled and residual) shared small positive relationships with these negative peer interactions. Conversely, Mallinson-Howard et al. (2019) found that perfectionistic strivings and perfectionistic concerns, when unpartialled, shared medium positive relationships with antisocial behaviour toward teammates and opponents, and that residual perfectionistic strivings and perfectionistic concerns shared small positive relationships with antisocial behaviour.

More research has begun to emerge examining the relationship between perfectionism and performance. Research findings appear relatively consistent. In regards to perceived performance, perfectionistic strivings was typically positively related to perceived performance and perfectionistic concerns was unrelated (e.g., Haraldsen, et al., 2020), or was negatively related (e.g., Květon et al., 2021), to perceived performance. In regards to actual performance, a similar pattern is evident. Perfectionistic strivings was typically positively related to actual performance whereas perfectionistic concerns was typically negatively related or unrelated to actual performance. This pattern was evident for golf putting (Lizmore et al., 2019), basketball free throws (Madigan et al., 2018), and a range of physical fitness testing (Mallinson-Howard et al., 2021).

In summary, based on the findings of previous reviews and our new review, we see some consensus for the independent effects of perfectionistic concerns and perfectionistic strivings. Perfectionistic concerns are typically problematic as they demonstrate inverse relationships with a range of adaptive characteristics (e.g., positive affect, self-esteem, and social support) and positive relationships with a range of maladaptive characteristics (e.g., negative affect, fear of failure, and avoidant coping) in sport, dance and exercise. When perfectionistic concerns are partialled from perfectionistic strivings, residual perfectionistic concerns do not appear to be discernibly different in terms of their effects. By contrast,

perfectionistic strivings are more ambiguous. Specifically, perfectionistic strivings demonstrate positive relationships with both adaptive (e.g., positive affect, task orientation, and self-confidence) and maladaptive characteristics (e.g., negative affect, ego orientation, and self-blame) in sport, dance and exercise. Some of this ambiguity is explained by the positive correlation between perfectionistic strivings and perfectionistic concerns. That is, when perfectionistic strivings are partialled from perfectionistic concerns, residual perfectionistic strivings can demonstrate positive relationships with adaptive characteristics (e.g., hope for success, mastery-approach goals, and social support) and non-significant or inverse relationships with maladaptive characteristics (e.g., anxiety, fear of failure, and negative affect).

The Case for Total Unique Effects and Relative Weights

A shortcoming of previous reviews in this area, including our own, is that they fail to resolve the tug of war between perfectionistic strivings and perfectionistic concerns. On one hand, we have perfectionistic concerns pulling towards more problematic outcomes and, on the other hand, we have perfectionistic strivings pulling towards less problematic outcomes and some desirable outcomes such as better athletic performance. For many researchers and practitioners this is an unhelpful state of affairs when seeking to advise, educate, and inform others about perfectionism. It is also unnecessary because the partialling approaches described in this chapter can be used to determine the overall effects of perfectionism. That is, they can be used to understand whether athletes, dancers, and exercisers are typically better or worse off because of perfectionism depending on the criterion variable being measured. This is achieved by determining the overall effect of perfectionism and weighing the relative contributions of perfectionistic strivings and perfectionistic concerns to that effect.

Creating total perfectionism scores is not new. Indeed, in the first study of perfectionism in sport, Frost and Henderson (1991) proposed that a total perfectionism score could be calculated as the sum of the subscales included on his multidimensional perfectionism instrument. However, simply adding subscales together provides us with little means to account for the different and unique effects of each dimension. Stoeber et al. (2020) recently attempted to address this shortcoming by calculating a *combined effect* of perfectionistic strivings and concerns. To do so, they adapted the regression equations from the 2 x 2 model of perfectionism (see Chapter 6 in this book) so to compare the effects of a non-perfectionism subtype of perfectionism (low in both perfectionistic strivings and perfectionistic concerns) with a mixed perfectionism subtype (high in both perfectionistic strivings and perfectionistic concerns). The combined effect approach provides a useful way for researchers to assess differences in outcomes between two important subtypes and was the first to recognise the usefulness of deriving an overall effect of perfectionism.

With Stoeber et al.'s (2020) combined effects approach as impetus, Hill et al. (2021) proposed the idea of a *total unique effect* (TUE) that could also be used to determine if perfectionism is, overall, adaptive, maladaptive, or neutral. Unlike, the combined effect approach, the total unique effect does not rely on a "pick-a-point" approach (viz. high versus low scores) or comparison of subtypes. Rather, it is based on summing the unique effects of perfectionistic strivings and perfectionistic concerns to derive a total effect. TUE is calculated by summing the two standardised residual regression coefficients (TUE = βPS + βPC). These are partialled effects that are very similar to the semi-partial correlations introduced earlier. By adding the effects together, TUE is interpreted as the change in the criterion variable following a one standard deviation increase in both perfectionistic strivings and perfectionistic concerns.

As should be evident, TUE is determined by the strength and the direction of the effects of perfectionistic strivings and perfectionistic concerns. This means that when perfectionistic strivings and perfectionistic concerns pull equally in opposing directions in relation to a given outcome, the TUE will signal perfectionism as neutral. When the pull of perfectionistic concerns is stronger (or in cases where perfectionistic strivings and perfectionistic concerns pull in the same direction for an undesirable outcome), the TUE will signal perfectionism as, overall, maladaptive. When the pull of perfectionistic strivings is stronger, the TUE will typically signal that perfectionism is, overall, adaptive (again depending on the criterion variable, though of course). We can test the significance of the TUE by calculating it's standard error (SE) and 95% confidence intervals. A computational example for how to calculate TUE is provided in Hill et al. (2021). Code for R is also available (Hill, 2022a), as is more user-friendly web-based application (Hill, 2022b).

Once TUE is calculated, the contribution of residual perfectionistic strivings and residual perfectionistic concerns to the overall effects is determined by calculating their relative weights. By calculating relative weights, we can assess the percentage of variance in the criterion variable explained by residual perfectionistic strivings or residual perfectionistic concerns. The relative weight can be considered an effect size for residual perfectionistic strivings and residual perfectionistic concerns in context of the TUE. As such, the relative weights also tell us which dimension is more important for a particular criterion variable. So far, the use of TUE has been illustrated using research outside of sport, dance, and exercise (Hill et al., 2021). To show what insight can be gained from applying it to research in these domains, we have illustrated the approach for some of the effects observed in Hill et al (2018) meta-analysis. The results are displayed in Table 4.2.

[Table 4.2 here]

In applying the TUE to the meta-analytical data in sport we can draw conclusions regarding the likely overall effects of perfectionism as an athlete becomes more perfectionistic. Starting with motivation, for task orientation, the non-significant TUE suggests that perfectionism is, overall, neutral. This might be surprising as there is a clear positive effect for perfectionistic strivings but as perfectionistic concerns is pulling in the opposing direction to a similar degree there is no "net gain" for perfectionistic athletes in regards to motivation for this goal orientation. For ego orientation, TUE suggests that, overall, perfectionism is maladaptive. So, as athletes become more perfectionistic, we can expect to deal with the problematic motivation issues that arise from being more ego-oriented (and not task-oriented). In examining the relative weights, we can see that perfectionistic strivings largely accounts for the prediction of task orientation whereas perfectionistic strivings and perfectionistic concerns are equally important in predicting ego orientation.

To consider athlete wellbeing we can use self-confidence and depression as proxies. Like with task orientation, calculation of TUE suggests that there is no net gain of being perfectionistic for self-confidence with increases in perfectionistic strivings and perfectionistic concerns resulting in, overall, a neutral effect. However, based on TUE we can expect athletes to report higher depressive symptoms so in this regard perfectionism is, overall, maladaptive. Indeed, this was the largest total effect we observed in this set of examples. In reviewing the relative weights, we can see a similar contribution to the prediction of self-confidence for the two dimensions of perfectionism but, by some way, perfectionistic concerns accounts for the prediction of depressive symptoms.

The last criterion variable we consider is athletic performance. In this case we see an overall adaptive effect with increases in perfectionism resulting in better athletic performance. There are complexities to this relationship, of course, and we remain unconvinced of the benefits of perfectionism for athlete performance for most people, most of the time. Nonetheless, we have illustrated here that current evidence suggests perfectionism may aid athlete performance, albeit to a small degree. The relative weights in this regard are important, too, as they show, as you would expect, the prediction of performance is almost entirely due to perfectionistic strivings.

Although these TUEs and relative weights are only a small set of examples and are limited to sport, they provide us with important insight into whether, overall, perfectionism is neutral, maladaptive or adaptive. Driven predominantly by perfectionistic strivings, perfectionism appears to offer some small benefit to athletic performance, but at what cost? An overall association with an ego orientation and neutral effects for task orientation and self-confidence alludes to potential motivational difficulties. Furthermore, due predominantly to the pull of perfectionistic concerns, perfectionism is associated with increased risk of maladjustment in the form of depressive symptoms. This is aligned with the TUEs we have seen outside of sport that show maladaptive effects for anxiety, burnout, depression, eating disorders and suicide ideation (Hill et al., 2021). Based on this evidence, we contend that perfectionism is most likely, overall, maladaptive for athletes, dancers, and exercisers.

Concluding comments

In this chapter we described an independent effects approach to examining the two main dimensions of perfectionism and a new approach that focuses on deriving their overall effect and relative weights. Based on previous reviews and our updated review, we believe there is now sufficient evidence to derive consensus regarding the likely effects of

perfectionistic strivings and perfectionistic concerns in sport, dance, and exercise. Because perfectionistic concerns are consistently associated with maladaptive characteristics, we can expect higher levels to undermine motivation and contribute to personal difficulties. Because perfectionistic strivings display a mixed pattern of adaptive and maladaptive characteristics, they are best considered ambiguous. In addition, when examining residual perfectionistic strivings, they appear more adaptive in relation to well-being, motivation, and performance. Beyond these conclusions, if we wish to determine whether, overall, perfectionism is adaptive, maladaptive, or neutral, we need to add the contributions of perfectionistic strivings and perfectionistic concerns to calculate a total effect. Doing so suggests that, overall, perfectionism may aid performance to a small degree but to a much larger degree is likely to be maladaptive for athletes due to the contribution of perfectionistic concerns. Further research is required to establish whether these total effects and conclusions are also evident in dance and exercise, as well as for a broader range of psychological outcomes.

Note.; Intru. = Instrument, CAPS = Child and Adolescent Perfectionism Scale (Flett et al., 2001), HF-MPS = Multidimensional Perfectionism Scale (Hewitt & Flett, 1991), HF-MPS-b = Brief version of Multidimensional Perfectionism Scales (Cox, Enns, & Clara, 2002 or Burgess, Frost, & DiBartolo, 2016), APS-R = Almost Perfect Scale-Revised (Slaney et al., 2001), F-MPS = Multidimensional Perfectionism Scale (Frost et al., 1990); FMPS-b = Brief version of Multidimensional Perfectionism Scale (Cox et al., 2002); S-MPS Sport Multidimensional Perfectionism Scale (Dunn et al., 2006); S-MPS-2 Sport Multidimensional Perfectionism Scale 2 (Gotwals et al., 2010); AE-MPS = Multiple Perfectionism Scale for Sport (Anshel & Eom, 2003); MIPS = Multidimensional Inventory of Perfectionism in Sport (Stoeber, Otto, & Stoll, 2006); PI = Perfectionism Inventory (R. W. Hill et al., 2004);
CPI = Chinese Perfectionism Inventory (Cheng & Hardy, 2016); PSQ = Perfectionism in Sport Questionnaire (Waleriańczyk & Stolarski, 2016); SOP = self-oriented perfectionism, HS = High standards, SP = Striving for perfection, PST = Personal standards, SE = Striving for excellence; PS+ = A composite of multiple subscales indicative of perfectionistic strivings; SPP = Socially prescribed perfectionism, D = Discrepancy, CM = Concern over mistakes, DA = Doubts about action, NRI = Negative reactions to imperfection; PS/O = subscale that includes both personal standards and organisation; PS = single subscale of perfectionistic strivings from PSQ; PC = single subscale of perfectionistic concerns from PSQ; PS+ = a composite of multiple subscales indicative of perfectionistic strivings; PC+ = a composite of multiple subscales indicative of perfectionistic concerns; CP = A combination of subscales from labelled Conscientious Perfectionism derived from subscales of Perfectionism Inventory; SP = A combination of subscales from labelled Self-Evaluative Perfectionism derived from subscales of Perfectionism Inventory; BO = Burnout; ED = Exercise dependence, FOF = Fear of failure; CE = Compulsive exercise; MT = Mental toughness; [a] = Sub-facets also available in article; *r* = bivariate correlation coefficient; *pr* = partial correlation coefficient. † = correlations presented are for perfectionism scores measured at time one and/or pre-intervention. ‡ = Spearman's rank correlations. Bold = $p < .05$

Table 4.2 *Meta-analytical relationships, total unique effects and relative weights*

Criterion variables	*k*	*N*	$r_{(PS\ PC)}$	$r_{(PS\ Y)}$	$r_{(PC\ Y)}$	β_{PS}	β_{PC}	TE [95% CI]	RW_{PS} (%)	RW_{PC} (%)	R^2_{MODEL}
Task orientation	8	2877	.36	.15	-.07	.20	-.14	.06 [-.00, .12]	0.03 (71.91)	0.01 (28.09)	0.04
Ego orientation	8	2877	.36	.22	.22	.16	.16	.32 [.27, .38]	0.04 (50.00)	0.04 (50.00)	0.07
Self-confidence	9	1300	.47	.16	-.24	.35	-.41	-.05 [-.15, .04]	0.06 (39.55)	0.09 (60.45)	0.15
Depressive symptoms	5	963	.35	.17	.42	.03	.41	.44 [.34, .53]	0.01 (8.33)	0.16 (91.67)	0.18
Athletic performance	6	684	.45	.23	.06	.25	-.06	.20 [.07, .33]	0.05 (94.60)	0.00 (5.40)	0.06

Note. k = Number of effect sizes. N = Number of participants; DV = Dependent variable. β = Standardised regression coefficient. TUE = Total unique effect (βPS + βPC; units of standard deviations of DV per standard deviation of PS + PC). RW = Relative weight. PS = Perfectionistic strivings. PC = Perfectionistic concerns. Rounding to two decimal places accounts for any differences between βPS + βPC and TUE. If 95% CI (confidence intervals) do not include zero, the TUE is statistically significant ($p < .05$). Harmonic mean of sample size and average PS-PC correlation used to calculate effects.

Figure 1. *A depiction of unpartialled (left), partialled (middle), and semi-partialled (right) relationship of perfectionistic strivings on a criterion variable controlling for perfectionistic concerns.*
