17TH WORLD CONGRESS ON PUBLIC HEALTH

2023 May 2-6 ROME ITALY

ABSTRACT BOOK

Abstract book by:

ORGANISING COMMITTEE

CMC

The three organising partners of the 17th World Congress on Public Health established a Congress Management Committee (CMC) consisting of representatives of WFPHA, SItI, ASPHER and the PCO. The CMC has the full managerial and financial management responsibility for the Congress.

Chair: Walter Ricciardi

Members:

Luis Eugenio de Souza – WFPHA
Bettina Borisch – WFPHA
Marta Lomazzi – WFPHA
Italo Angelillo – SItI
Antonio Ferro – SItI
Roberta Siliquini – SItI
Carlo Signorelli – ASPHER
John Middleton – ASPHER
Robert Otok – ASPHER

ICC

The International Congress Council (ICC) consisted of the Congress Management Committee and international public health experts representing various regions of the WFPHA, international health organisations, European health non-governmental organisations and Italian universities and institutes. The ICC in particular develops, in consultation with the CMC, the scientific programme including subthemes and plenary programme of the WCPH and identify speakers/panellists/moderators of the plenary sessions.

Chair: Walter Ricciardi

Members:

Mohannad Al Nsour (Jordan)
Elena Alonzo (Italy)
Woldekidan Kifle Amde (South Africa)
Yaneer Bar-Yam (USA)
Maurício Barreto (Brazil)
Stefan Buttigieg (Malta)
Mary Codd (Ireland)
Kasia Czabanowska (The Netherlands)
Maria Saenz Del Rocio (Costa Rica)
Enrico Di Rosa (Italy)
Alberto Fedele (Italy)
Rok Hrzcic (Slovenia)
Gregory Kolt (Australia)
Rüdiger Krech (WHO)
Jose M. Martin-Moreno (Spain)
Alison McCallum (United Kingdom)
Martin McKee (United Kingdom)
Michael Moore (Australia)
Jean Marie Okwo Bele (Congo)
Gaetano Pelissero (Italy)
Gaetano Privitera (Italy)
Srinath K. Reddy (India)
Malabika Sarker (Bangladesh)
Luca Gino Sbrogiò (Italy)
Ines Siepmann (USA)
Giorgio Solimano (Chile)
Emanuele Torri (Italy)
Paolo Villari (Italy)
Francesco Vitale (Italy)

ISC

The International Scientific Committee (ISC) consists of experienced public health experts from around the world nominated by WFPHA, SItI and Aspher. It mainly advises the ICC on scientific matters of the conference and contributes to the scientific evaluation of the conference. We would like to thank the ISC for their support.

Aim & Scope

Population Medicine is an open-access double-blind peer-reviewed scientific journal that encompasses all aspects of population, preventive, and public health research including health care systems and health care delivery. Its broader goal is to address major and diverse health issues, to provide evidence-based information to professionals at all levels of the health care system, and to inform policymakers who are responsible for the formation of health policies that can lead to evidence-based actions.

Editorial Board

Editor-in-Chief

Evridiki Patelarou

MD, RN, MPH, PhD, Professor of Epidemiology, School of Nursing, Hellenic Mediterranean University, Greece

Editorial Board

Israel Agaku,

Lecturer, Oral Health Policy and Epidemiology, Department of Oral Health Policy and Epidemiology, Harvard School of Dental Medicine, MA, United States

Hend Alqaderi

Lecturer in Oral Health Policy and Epidemiology, Harvard School of Dental Medicine, MA, United States

Jay Atanda

Office of Science Policy and Analysis (OSPA), National Institutes of Health, United States

Kostas Athanasakis

Assistant Professor of Health Economics and Health Technology Assessment, Department of Public Health Policy School of Public Health, University of West Attica, Greece

Muath A. Aldosari

Lecturer, Oral Health Policy and Epidemiology, Harvard School of Dental Medicine, Harvard University, Boston, United States

Arzu Beklen

Department of Periodontology, Faculty of Dentistry, Eskisehir Osmangazi University, Turkey

Nurcan Buduneli

Professor, Department of Periodontology, Faculty of Dentistry, Ege University, Turkey

Aslı Çarkoğlu

Associate Professor, Department of Psychology, Kadir Has University, Istanbul, Turkey

Onyema Greg Chido-Amajuoyi

Postdoctoral Fellow, University of Texas MD Anderson Cancer, TX, United States

Daniel Erim

Director, Real World Value & Evidence, Market Access Analytics, Johnson & Johnson, United States

Wayne Gao

Associate Professor, College of Public Health, Taipei Medical University, Taiwan

Charis Girvalaki

Director, European Cancer Patient Coalition, Brussels, Belgium

Michele Hilton-Boon

Research Fellow in Feminist Economics, Glasgow Caledonian University, United Kingdom

Takashi Hanioka

Professor, Department of Community and Preventive Dentistry, Fukuoka Dental College, Japan

Bruce Kirenga

Pulmonology Unit, Department of Medicine, Makerere University, Mulago Hospital, Kampala, Uganda

Dilek Karadoğan

Associate professor, Pulmonary Medicine, Department of Chest Diseases, Recep Tayyip Erdoğan University, Turkey

Alexander Mathioudakis

Clinical Research Fellow and Honorary Lecturer, Division of Infection, Immunity and Respiratory Medicine, The University of Manchester, Manchester, United Kingdom

Enkeleint A. Mechili

Department of Healthcare, Faculty of Public Health, University of Vlora, Albania

Ute Mons

Professor, Group head - Cardiovascular Epidemiology of Ageing, University of Cologne, Germany

Jantel Nelson

Great Life Counseling Center, United States

Revati Phalkey

Head, Climate Change and Health Unit, UK Health Security Agency, United Kingdom

Oluwakemi Odukoya

Department of Community Health and Primary Care, College of Medicine, University of Lagos, Nigeria

Krzysztof Przewoźniak

Department of Cancer Epidemiology and Prevention, Maria Skłodowska-Curie National Research Institute of Oncology, Poland

Mays Shamout

Epidemic Intelligence Service Officer, National Center for Chronic Disease Prevention and Health Promotion, CDC, United States

Kimón Stamatelopoulos

Associate Professor of Clinical Therapeutics and Cardiology, School of Medicine, National and Kapodistrian University of Athens, Greece

Antigona Trofor

Professor of Respiratory Medicine, Department of Pulmonary Medicine, University of Medicine and Pharmacy "Gr. T. Popa" Iasi, Romania

Tina Tsafa

Centre for Food Technology and Research, Department of Mass Communication, Benue State University, Nigeria

Manolis Tzatzarakis

Associate Professor, Laboratory of Toxicology, Medical School, University of Crete, Greece

Uyoyo Omaduvie, Academic primary care physician/faculty, Tufts Medical Center, Boston, United States

Strategic Development Editor

Constantine Vardavas

Medical School, University of Crete, Greece & Harvard School of Dental Medicine, United States

Table of Contents

Musculoskeletal symptoms and disorders, and related knowledge, attitude and practices among female textile workers in Karachi, Pakistan: a cross-sectional study	46
Heart Health of Filipino senior workers	46
Awareness and practice of family planning services among married men in area of Yemen	46
Inequalities in primary and secondary healthcare use among people living with dementia in England	46
Concepts and definitions of healthy ageing: a systematic review and synthesis of theoretical models	46
The Adult Immunization Board (AIB): a platform to provide multidisciplinary support for the implementation and optimization of adult immunization in Europe	47
Impact of multimorbidity on health care utilisation in Australian older adults aged 45 years and over: a large population-based data linkage cohort study	47
Identifying risk factors for becoming obese: a record linkage longitudinal study in metropolitan Sydney using the 45 and Up Study	47
Use of wearable sensor technology to detect risk of fall in Indian older adults	48
Social wellbeing among urban elderly in India: exploring the role of multidimensional health	48
How multimorbidity affects trajectories in functional limitation and quality of life among middle-aged and older adults: longitudinal findings from the 2013-2020 survey of health, ageing, and retirement in Europe	48
Post acute care: cui prodest? A 1-year retrospective observational study	48
National Recovery and Resilience Plan - using the Health Project programming tool in Sardinia: Social Health Districts' mortality and aging index analysis from 2017 to 2021	49
Association of serum uric acid with body mass index in the United Arab Emirates UAE healthy future pilot study	49
Multimorbidity and out-of-pocket expenditure on medicine in Europe: longitudinal analysis of 13 European Health Systems between 2013 and 2015	49
The psoriasis comorbidome	49
Selenium exposure and oxidative stress and genotoxicity risk in a healthy Italian population: a cross sectional study	50
Key considerations for the implementation of active assisted living systems to support older adult care	50
Importance and determinants of advance directives and healthcare proxy use among the oldest-old	50
Transition to retirement impact on depressive symptoms: results from a longitudinal analysis within the Survey of Health, Ageing and Retirement in Europe (SHARE) project	50
Developing new models for integrated community health and social care for dependent older people: the case of Programa Maior Cuidado in Brazil	51
Patient-reported outcomes in robotic total knee arthroplasty: a retrospective cohort study with RObotic Surgical Assistant system	51
Empowerment of healthy ageing through integrated care managers in China	51
Predictors of Chronic Pain: comparison between older adults with and without life-long cognitive disability	51
Development and validation of a dietary diversity score for French older adults	52
Association of pain and depression among middle-aged and older adults of India	52
The integrated pathways of care in the social and healthcare services: the AgICOT experience in Teramo, Italy	52
Gender differences in global Disability-Adjusted Life Years (DALYs): a descriptive Analysis of the global burden of disease study 2021	53
Reliability and validity of the bone health literacy questionnaire for middle-aged and elderly women	53
Serological responses up to 9 months following COVID - 19 mRNA vaccination in residents and healthcare workers of long - term care facilities: a multicenter prospective cohort study in Northern Italy	53
Role of vegetarian and plant-based diet in the prevention of mild cognitive impairment and dementia	53
Do meta-analyses of randomized controlled trials estimate the true population effects of multiple risk factor interventions?	53
Assessing the quality of the built environment in dementia: a framework to evaluate long-term care facilities	54
Longitudinal clustering of health behaviours and their association with health outcomes in older adults in England: a latent class analysis	54
Suffering in Silence: Urinary Incontinence among Bangladeshi Women	54
Health outcomes and physiological adaptations of regular physical activity among young individuals	54
The role of the built environment in dementia: evolution and adaptation of an innovative care model through the SARS-CoV-2 pandemic ...	55
Socioeconomic differences in brain white matter microstructure and associated cognitive performance in middle to older adulthood	55
Age Differences in Incidence Rates and In-hospital Outcomes among adults with Stroke or transient ischemic attack: a 10-year time-series analysis	55
The effect of physical activity on health-related quality of life in older people living in residential care settings: preliminary results from an Italian sample	56
COVID-19 vaccination among older adults in India: a case of underrepresentation	56
Socioeconomic predictors over the life course of healthy ageing index in older Eastern Europeans	56
The role of folate metabolism enzymes snps in non-obstructive azoospermia: A systematic review and meta-analysis	57
Prevalence and factors associated with elder abuse in an eastern state of India	57
A pilot study on evaluating relationship between steps and motion in a smart home environment Background:	57
Barriers and facilitators for the successful implementation of antimicrobial stewardship interventions in long-term care facilities: a scoping review	57
Realist evaluation of the impact, viability and transferability of an alcohol harm reduction support program based on mental health recovery: the vitae study: First results	58
Association between household air pollution and cognitive health among older adults in India: A multiple mediation approach through depression and insomnia	58

Older adults' risk profiles for intense care transition patterns: 15-year results from a swedish population-based study	58
Impact of COVID-19 on football players' injuries	58
Did covid-19 pandemic modify palliative care utilisation in 2020? a retrospective observational study comparing 2020 and 2019 administrative data in tuscany, Italy	58
Community-based program focused on social support limits covid-19 mortality: a retrospective cohort study	59

Musculoskeletal symptoms and disorders, and related knowledge, attitude and practices among female textile workers in Karachi, Pakistan: a cross-sectional study

Ali Hussaini¹

¹Aga Khan University, Karachi, Pakistan

Objectives: The aim of this study was to determine the prevalence of Musculoskeletal symptoms and disorders (MSD) and to assess Knowledge, Attitude and Practices regarding Musculoskeletal symptoms and disorders among female textile workers in Karachi, Pakistan. **Methodology:** To assess the prevalence of MSD, we used the adopted version of Nordic Musculoskeletal Questionnaire (NMQ). For assessing individual and work-related factors, a structured questionnaire was developed and used. Data was captured on EpiData and analyzed using SPSS 19. Percentages and frequencies were calculated for musculoskeletal symptoms and disorders, socio-demographic and work-related factors. Standard deviation (SD) and mean were calculated for age, duration of work and income. For KAP variables, responses were coded as "positive" or "negative". Those scoring "positive" were considered as having good knowledge, attitude, and practices.

Results: 311 respondents participated in this study. 253 (81.4%) of the female textile workers reported musculoskeletal symptoms. The Lower back was the most frequently affected region (71.7%), followed by shoulders (70.7%), neck (43.4%), forearm and elbow (24.4%), hands and wrist (20.6%), upper arms (15.1%) and upper back (5.1%). Self-reported average difficulty of pain was moderate, and most individuals (29.6–53.1%) reported duration of pain to be between 3-5 days. Nearly 69.5% female workers were very dissatisfied with their working space. Frequency of musculoskeletal complaints were popular among 26-35 years of age bracket. Higher monthly income, up to 5 years spent working in the textile industry, marital status and lower educational attainment all correlated positively with complaints. Those with MSD complaints were more likely to have better knowledge and safer practices score. **Conclusions:** Here is a high prevalence of musculoskeletal symptoms and disorders among female textile workers in economically developing countries. Preventive measures and worksite interventions are needed to reduce work-related musculoskeletal disorders in this population. Health insurance, treatment and reimbursement schemes should be launched.

Heart Health of Filipino senior workers

Meryl Quero-Asa¹

¹Balai Obrero Foundation, Philippines

The study uses a mixed approach which includes using an online survey to quantitatively describe the cardiovascular health condition of senior working people, and its relation to access to food, medicine, and health care. The sample is taken from worker communities or neighborhoods near factory belts in the capital of the Philippines. Linear regression is used to analyze the social determinants of health. The study shows the condition of hunger and poor health among the elderly amid job and livelihood insecurity that was exacerbated by the pandemic. **Keywords:** senior workers, elderly health, job insecurity, healthcare

Awareness and practice of family planning services among married men in area of Yemen

Abdulla Bagahizel¹

¹Hadhrumout University, Yemen

Background and objectives: Family planning is the capacity of people and couples to expect and accomplish their ideal number of youngsters and the dispersing and timing of their births. This study aimed to assess the level of awareness and practice of family planning methods among married men in Mukalla public hospitals.

Methodology: A descriptive cross-sectional study was conducted in Al-Mukalla city during the time period of (2021-2022). 366 married men were recruited using interviewer-administered questionnaires with close-ended questions which consisted of three sections including demographic characteristics, awareness and practice sections. The collected data was computerized and summarized numerically and graphically using Statistical Package for the Social Sciences (SPSS) version 25. Nonparametric statistical tests were used to assess the mean differences of sociodemographic variables with the knowledge, attitudes, and practices scores toward family planning.

Results: Among the study participants, the mean age was 35.25 (± 7.959), and most of them (60.1%) had married within 10 years. The Findings of the study revealed that the majority of the participants (51.9%) had a good awareness

of family planning methods with a mean score of 7.27 (± 2.307). Based on their responses, the most common method known and practiced by them as oral contraceptive pills. The most common reasons for not using family planning methods among men were the wish for more children and the fear of side effects. **Conclusions:** The study concludes that most men have a piece of comprehensive knowledge. However, the practice of family planning methods is still inadequate. Our study suggests directing more health education interventions and promotion to enhance the utilization of family planning Methods.

Inequalities in primary and secondary healthcare use among people living with dementia in England

James Watson¹

¹NIHR Applied Research Collaboration North West Coast (ARC NWC), The University of Liverpool, United Kingdom

Background and objectives: In the UK healthcare services for people living with dementia (PLWD) are under pressure, and central government have not adhered to additional funding commitments. The UK population with dementia is expected to surpass 1 million by the year 2024, and the health and social care costs for PLWD set to treble by 2040, making it critical we understand how and to what extent, PLWD differentially use healthcare. This study aimed to explore social and spatial variations in healthcare use among people diagnosed with dementia (2002-2016). **Methods:** Data were taken from Electronic Health Records of Clinical Practice Research Datalink General Practice patients in England ($n=142,302$). Healthcare contacts were standardised for the sample population, with rates of contacts per year calculated for three primary healthcare types (GP observations, and both dementia and non-dementia medications) and three secondary (Accident and Emergency (A&E) attendances, and emergency and elective hospital admissions). Generalised linear regression models, fully-adjusted for confounders enabled identification of differences in healthcare use by socio-economic, demographic and geographic factors. The sample was stratified by dementia onset, with a subsequent series of analyses generated for each healthcare type, Resulting in 12 regression models.

Results: The study highlights several social and spatial inequalities in healthcare use among PLWD. Men, PLWD from White ethnicity groups, in more deprived areas, and from rural areas, have greater use of healthcare services more closely associated with negative health outcomes, including less frequent GP contact and medications, and greater use of secondary healthcare.

Conclusions: Social and systemic measures are needed to reduce healthcare use inequalities among PLWD. These include: improved healthcare continuity, more frequent and better-quality health checks and medicines reviews, more culturally appropriate services, as well as greater and more accessible treatment and improved infrastructure for underserved communities.

Concepts and definitions of healthy ageing: a systematic review and synthesis of theoretical models

Marilyne Menassa¹, Karien Stronks², Farnaz Khatami³, Zayne Díaz³, Octavio Espinola³, Magda Gamba³, Oche Itodo³, Chepkoech Buttia³, Faina Wehrli³, Beatrice Minder⁴, Minerva Velarde⁵, Oscar Franco⁶

¹Graduate School of Health Sciences, Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, ²Department of Public and Occupational Health, Amsterdam University Medical Centers, University of Amsterdam, Netherlands, ³Institute of Social and Preventive Medicine, University of Bern, Switzerland, ⁴Public Health and Primary Care Library, University of Bern, Switzerland, ⁵Department of Radiology and Medical Informatics, University of Geneva, Switzerland, ⁶Department of Public Health, Julius Center for Health Science and Primary Care, UMC Utrecht, University of Utrecht, Netherlands

Background: Healthy ageing (HA) has been defined using multiple approaches. We aim to produce a comprehensive overview and analysis of the theoretical models underpinning this concept and its associated normative terms and definitions.

Methods: We conducted a systematic review of peer-reviewed HA models in Embase.com, Medline(Ovid), Cochrane CENTRAL, CINAHL, PsycINFO, and Web of Science until August 2022. Original theoretical papers, concept analyses, and reviews that proposed new models were included. Operational models/definitions, lifespan development psychology theories and mechanisms of ageing were excluded. We followed an iterative approach to extract the models' characteristics and thematically analyze them based on the approach of Walker and Avant. The protocol was registered in PROSPERO (CRD42021238796).

Results: Out of 10,741 records, we included 59 papers comprising 65 models/definitions, published in English (1960-2022) from 16 countries in Europe, Asia, and America. Human ageing was described using 12 normative terms, mainly (models (%)): successful (34 (52%)), healthy (eight (12%)), well (five (8%)), and active (four (6%)). We identified intrinsic/extrinsic factors interacting throughout the life course, adaptive processes as attributes, and outcomes describing patterns of ageing across objective and subjective dimensions (number of models/definitions): cognitive(62), psychological(53), physical (49), social (49), environmental (19), spiritual (16), economic (13), cultural (eight), political (six), and demographic (four) dimensions. Three types of models emerged: health-state outcomes (three), adaptations across the life course (31), or a combination of both (31). Two additional sub-classifications emphasized person-environment congruence and health promotion.

Conclusions: HA is heterogeneously termed and conceptualized multidimensionally as adaptive processes of dynamic person-environment interactions to ageing, health-state outcomes, or both. Congruence with the living environment and health promotion/empowerment are emphasized. Our model classification provides a basis for harmonizing conceptual terms and dimensions that can guide research and comparisons of empirical Findings. This would inform social and health policies enabling HA for populations in various contexts.

The Adult Immunization Board (AIB): a platform to provide multidisciplinary support for the implementation and optimization of adult immunization in Europe

Jade Pattyn¹, Marco Del Riccio², Angela Bechini², Greet Hendrickx¹, Sara Boccacini², Pierre Damme³, Paolo Bonanni²

¹Centre for the Evaluation of Vaccination, Vaccine & Infectious Disease Institute, University of Antwerp, Belgium, ²Department of Health Sciences, University of Florence, Italy, ³Centre for the Evaluation of Vaccination, Vaccine and Infectious Disease Institute, University of Antwerp, Belgium

Background: The low adult vaccination coverage and the barriers experienced during the implementation of the COVID-19 vaccination strategies in almost all European countries underline the need for a thorough reflection on adult immunization programs in Europe. Therefore, the teams of Prof. Bonanni - University of Florence and Prof. Van Damme - University of Antwerp joined forces to create an adult immunization board (AIB) based on years of experience with the Viral Hepatitis Prevention Board (created in 1992) and the HPV board (created in 2015). The AIB will be an independent, international, and multidisciplinary group of experts in adult immunization. The experts will set the strategy and define the actions of the AIB.

Materials: AIB operates by organizing two yearly meetings: 1) Technical meeting covering technical aspects of adult immunization such as tailored vaccine services and communication for adults, electronic vaccine registries, adult immunization schedules, vaccine equity, coadministration of vaccines etc. 2) Country meeting to discuss country/region-specific aspects of adult immunization together with local experts.

Results: In November 2022, the AIB secretariat organized a Kick-off meeting with experts to establish the basic structure/functions of the Board, discuss the main Objectives, and plan future meetings. Experts from different disciplines/sectors welcomed the AIB initiative. It was indicated that it is timely to have a closer look into adult vaccination and it was recognized that immunization needs a lifelong course and does not end after childhood. The new platform was well received and endorsed as an appropriate and effective way to share information and exchange ideas and experiences across disciplines and borders. In Q2/Q4 2023, the first AIB technical/country meetings are scheduled.

Conclusions: AIB will be a platform that brings together the different key European stakeholders on adult immunization in order to effectively contribute towards the implementation and optimization of adult immunization in Europe.

Impact of multimorbidity on health care utilisation in Australian older adults aged 45 years and over: a large population-based data linkage cohort study

A.Y.M. Kabir¹, Sameera Ansari², Damian Conway³, Joel Rhee⁴, An Tran⁵, Margo Barr⁵

¹Centre for Primary Health Care and Equity, University of New South Wales, Sydney, Australia, ²School of Population Health, University of New South Wales, Kensington, Australia, ³Population and Community Health Directorate, South Eastern Sydney Local Health District, Australia, ⁴School

of Population Health, University of New South Wales, Kensington, Australia, ⁵Centre for Primary Health Care and Equity, University of New South Wales, Kensington, Australia

Background: Multimorbidity (MM), co-occurrence of two or more chronic health conditions in an individual, is often used in the assessment of complex healthcare needs and their impact on health outcomes. Management of MM is complex, but little is known about the impact of MM on health care services. Methods: We conducted a cross-sectional study among people aged 45+ years in New South Wales, Australia, who completed baseline questionnaires in the 45 and Up Study between 2005-2009. Baseline questionnaire data were linked to hospital, primary care Medicare billings, emergency department (ED), and deaths registry data. Our outcome of interest was high use of health care services within the 3-year baseline period (averaged over the years before, during and after recruitment). People who died during that period were excluded. High use was defined as: ≥ 11 General Practice (GP) visits, ≥ 2 ED visits, and ≥ 2 hospital admissions. Prevalence ratios (PRs) were used to measure the impact of MM, and Poisson regression models were used to estimate adjusted and unadjusted PRs with 95% confidence intervals.

Results: Among 251,689 participants (46.5% male, and 46.1% aged <60 years), the overall prevalence of MM was 44.1% and prevalence increased with age: 32.2% in 45-59 years, 50.3% in 60-74 years, and 63.3% in 75+ years. After adjusting for confounding, MM was associated with high service use: adjusted PR (95% CI) was 2.27 (2.06-2.51) for high hospital use, 2.02 (1.98-2.06) for high GP use, and 2.04 (1.90-2.21) for high ED use. The impact of MM on health care utilisation was higher among the younger age group. Conclusions: This study illustrates the burden of multimorbidity on service use within the health system. It also highlights the need to examine and rationalise service provision and utilisation across the health system to assist people with multimorbidity efficiently manage their conditions.

Identifying risk factors for becoming obese: a record linkage longitudinal study in metropolitan Sydney using the 45 and Up Study

Alamgir Kabir¹, Kylie Vuong², Damian Conway³, Margaret Williamson⁴, Mark Harris⁴, Margo Barr⁴

¹Centre for Primary Health Care and Equity, University of New South Wales, Australia, ²School of Medicine and Dentistry, Griffith University, Australia, ³South Eastern Sydney Local Health District, Population and Community Health Directorate, Australia, ⁴Centre for Primary Health Care and Equity, University of New South Wales, Kensington, Australia

Background: Obesity is the fourth leading cause of mortality globally. Australia has one of the world's highest rates of adult obesity, with 31% being obese in 2017/2018, and increasing. If this trend continues, the Australian Bureau of Statistics predicts 18 million Australians will be obese or overweight by 2030. We aimed to identify risk factors for becoming obese among people aged 45 years and older. Methods: A record linkage longitudinal study of people from metropolitan Sydney was undertaken using data from the: 45 and Up Study at baseline (2005-2009) and first follow-up (2012-2015); Medicare Benefits Schedule; Pharmaceutical Benefits Scheme; and deaths registry. We examined risk factors for becoming obese (Body Mass Index [BMI]:30-40) at follow up (5-7 years after baseline), separately for people within the: healthy weight range (BMI:18.5- < 25), and overweight range (BMI: 25- <30) at baseline. We considered demographics, modifiable behaviours, health status, primary care usage, and medication use as covariates. Crude and adjusted relative risks (RR) were measured using Poisson regression model.

Results: At follow up, in the healthy weight range cohort, 1.1% (180 of 16,205) people became obese, and in the overweight range cohort, 12.7% (1939 of 15266) people became obese. In both cohorts, the following were associated with an increased risk of becoming obese: current smokers, physical functioning limitations, allied health services use through team care planning and use of psychiatric medications, while alcohol consumption and adequate physical activity were found to be protective. In the healthy weight cohort, high psychological distress was associated with an increased risk of becoming obese. In the overweight cohort, being female and full-time work were associated with increased risk, while older age was found to be protective. Conclusions: These findings should assist primary care clinicians to identify patients with characteristics that place them at risk of becoming obese for intervention.

Use of wearable sensor technology to detect risk of fall in Indian older adults

Snehal Kulkarni¹

¹School of Public Health, Faculty of Sustainability Studies, MIT-World Peace University, India

Background and Objectives: Approximately 28-35% of people aged 65 and older fall each year. As most of the falls occur during walking; evaluation of gait and balance impairment are considered as the most prevalent and sensitive predictors of fall. The population of older adults is expected to increase 193 million by 2050 in India. However, no such programme fall prevention programme exists to date in India. Therefore, the present study was undertaken to establish normative reference gait parameters for Indian older adults and identify older adults at risk of fall using wearable sensors. **Methodology:** This cross-sectional study was conducted in the Pune city, India among 659 community-dwelling older adults. Participants performed the Timed-up and go test (TUG) test fitted with the wearable sensors, which measured 59 gait parameters. Seven parameters were standardized for Indian older adults and fall risk of each individual was computed. Independent t-test, and one-way ANCOVA were used to establish normative gait parameters and predict risk of fall.

Results: The study reported a fall prevalence of 24.7%, with a mean stride length of 123.00 ± 15.19 cm and stride velocity of 110 ± 17.57 cm/s respectively. Significantly ($p < 0.05$) shorter stride length was observed in participants above 80 years of age (109.01 ± 18.08 cm). Using these gait parameters, the study found that 20% of the study participants were at low risk of fall, 30.5% medium risk, 25.5% had high risk and 24.1% were at very high risk of falling. The sensor reported a sensitivity of 85.71% (CI: 69.74%- 95.19%) and 56.02% (CI: 49.82%- 62.07%) specificity to predict falls. **Conclusions:** Wearable sensors are a dependable tool for identifying older adults at risk of falling in community settings with limited resources and expertise.

Social wellbeing among urban elderly in India: exploring the role of multidimensional health

Raghunath Mandi¹, Dhananjay Bansod²

¹Department of Public Health and Mortality Studies, International Institute for Population Sciences, Mumbai, India, ²Department of Public Health and Mortality Studies, International Institute for Population Sciences (IIPS), Mumbai, India

Background: Globally, the share of the population aged 65 and above is projected to rise from 10 percent in 2022 to 16 percent in 2050. India too will become the home for more than 350 million elderly by 2050. With ageing, people experience various crisis like loss of physical, mental, and social status and modification in their roles and responsibilities within family and society and paving their way towards dependency in life. This dependency on others deteriorates the quality of life and well-being among the geriatric population. The present study examines the influence of multidimensional health on the well-being among urban-dwelling elderly in India aged 60 and above.

Methodology: The sample was obtained from first wave of the Longitudinal Ageing Study in India (LASI). Social well-being was assessed based on the SWLS scale (Diener et al., 1985) among the urban elderly in India. Multivariate linear regression analysis was used to investigate the association between multidimensional health, sociodemographic variables and life satisfaction.

Results: The overall mean well-being score was 24.94 (SD=7.20) which is more than many developed countries like Spain, Mexico and China. Elderly with good physical, functional and mental health have been associated with higher well-being while having any depressive symptoms or any impairment was associated with lower life satisfaction among urban elderly. Apart from that, life satisfaction score differs significantly by socio-demographic characteristics (marital status, living arrangement, wealth and educational status).

Conclusions and Discussion: During old age a sense of companionship and good social networks are essential in enhancing well-being, whereas, perceived physical, mental and functional health are equally important in facilitating self-perception of ageing. Therefore, well-being among urban elderly should be looked not only from the perspective of individual factors (like health and socioeconomic status) but a broad socio-cultural dimensions should be inquired extensively to achieve successful aging.

How multimorbidity affects trajectories in functional limitation and quality of life among middle-aged and older adults:

longitudinal findings from the 2013-2020 survey of health, ageing, and retirement in Europe

Piotr Wilk¹

¹Western University, Canada

Background and Objective: The increased burden of multimorbidity is impacting the lives of people worldwide, restricting the ability of individuals to live autonomously and leading to a poorer quality of life. Improving or maintaining a good quality of life can be an important coping mechanism for individuals living with multimorbidity and functional limitation. This study assessed how multimorbidity affects the trajectories in functional limitation and quality of life as well as the relationship between these two trajectories in a sample of middle-aged and older adults.

Methods: Longitudinal prospective data came from the survey of health, ageing, and retirement in Europe, conducted in Luxembourg between 2013 and 2020, distributed across two age cohorts: 50-64 years old (n=897) and 65 years old and over (n=688). Multimorbidity was defined as the co-existence of two or more chronic conditions. Functional limitation was assessed by the summated score from the (instrumental) activities of daily living scales. Quality of life was assessed by the control, autonomy, self-realization and pleasure scale. We used latent growth curve modelling techniques to conduct the analysis.

Results: Our results suggest that, throughout the life course, middle-aged and older adults living with multimorbidity experienced poorer quality of life, were at a higher risk of functional limitation, and had a higher number of functional limitations than those without multimorbidity. At baseline and across time, functional limitation had a negative impact on quality of life. We also found that the impact of multimorbidity on functional limitation and quality of life varies across the life course.

Conclusions: The previously observed cross-sectional associations between multimorbidity, functional limitation, and quality of life are more persistent and can affect adults over the life course. Any future research on the interrelationship between multimorbidity, functional limitation, and quality of life should assess these effects separately for middle-aged and older adults.

Popul. Med. 2023;5(Supplement):A11

Post acute care: cui prodest? A 1-year retrospective observational study

Pietro Ballesini¹, Sabina Sanseverini², Ivo Venturini³, Sergio Rovesti², Athos Borghi⁴, Alessandro Callegaro⁵, Naïke Sola⁶, Piero Benatti³, Valeria Evandri³

¹Medical Urgency and Post-Acute Care, Department of Internal Medicine, Azienda Ospedaliero-Universitaria di Modena, Modena, Italy, ²Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, ³Department of Internal Medicine, Medical Urgency and Post-Acute Care, Azienda Ospedaliero-Universitaria di Modena, Italy, ⁴Post-Acute Care, Department of Internal Medicine, Medical Urgency and Post-Acute Care, ⁵Azienda Ospedaliero-Universitaria (AOU) di Modena, Italy, ⁶Management, Azienda Ospedaliero-Universitaria di Modena, Italy

Background: At the time of discharge from acute care (AC) hospital, many old patients are unable to return home and need a short or extended stay at skilled medical and nursing facilities in the hospital, post-acute care (PAC), for clinical stabilization and/or reactivation/rehabilitation. This work analyzes the characteristics of patients that needed hospitalization in PAC and the benefit for patients and hospital. **Methods:** We checked consecutively 272 patient's requests of transfer records from January 1 to December 31, 2020. We considered age, sex, assessment of the patients suitability for transfer and date, day of transfer to PAC, date and type of discharge, diagnosis, re-hospitalization, death during hospitalization or within 3-6 months etc.

Results: 12 patients (4.4%) were considered not suitable for PAC; 95 woman and 82 male were transfer to PAC; 45 woman and 38 male considered suitable were not transfer for "lack of beds". 26 patients (14.6%) transfer to PAC needed palliation versus 12 remained in AC. Patients discharged from PAC versus not transfer, due to "lack of beds", were fewer re-hospitalized at one and 3 months (7.3% vs 12%) and (14.6% vs 22.9%). For lack of beds in PAC, patients remained in AC 2116 days and were considered "bed blockers" long this period. In Italy PAC is remunerated "on a day" (about 150 Euros/day/patient) and from the day of the request's/evaluation's PAC the patient has already acquired its DRG, so we can consider that the hospital has renounced approximately to 317,400 thousand euros of reimbursements from the Region.

Conclusions: Who benefits from the PAC? 1) The patient, who have a lower rate of re-hospitalization; 2) The patient, who have an adequate and protected discharge path 3) the AC, that have more bed available 4) the hospital that has adequate healthcare reimbursement for the provided medical service.

DOI: 10.18332/popmed/165169

National Recovery and Resilience Plan - using the Health Project programming tool in Sardinia: Social Health Districts' mortality and aging index analysis from 2017 to 2021

Federica Cadoni¹, Sara Pani², Luigi Minerba³

¹School of Hygiene and Preventive Medicine, Medicine Faculty, University of Cagliari, Italy, ²School of Hygiene and Preventive Medicine, University of Cagliari, Cagliari, Italy, ³Medicine Faculty, School of Hygiene and Preventive Medicine, University of Cagliari, Cagliari, Italy

Background and Objective: A better reorganization of territorial assistance responses depends on identifying the specific social welfare needs of both individuals and collectivity. Focusing on Sardinia Region, in line with recent Italian National Recovery and Resilience Plan' indications, Population Medicine setting and Health Project programming tool, we should take into account its peculiar heterogeneity: population' size and demographic characteristics; variation in mortality; oro-geographical aspects of the Social-Health Districts (SHD).

Methods: Retrospective observational study on the Italian and Sardinian resident population from 2017 to 2021. Population (Istat demographic data detailed for each municipality to depict Sardinian SHD) divided into 21 age groups, each including five years (0-4/100+). Ratios: Aging index and age-adjusted standardized mortality ratios (SMRs) calculated for the period 2017-2019, for 2020 and 2021, divided by SHD (age groups 0-64/65+). Standardized death rate calculated for the 21 age groups (reference: Italian population, same year). The excess mortality compared to the average baseline deaths calculated for the years 2020 and 2021 (group 0-100+; 0-64; 65+).

Results: The regional trend of standardized mortality rate shows an increase in 2020 and a slight decrease in 2021, confirmed by the excess mortality analysis. The SMRs show instead an overall increase in all Districts from 2020 to 2021, except in 7 of them, for the 0-64 range. The aging index is progressively increasing in all Districts, more incisively in some areas.

Conclusions: Sardinia has the highest Italian aging index, with uneven dynamics across the Districts. The demographic aging will heavily test healthcare and social security costs. Health professionals and policymakers should therefore work together using as key concepts healthy aging and aging in-place, and paying attention to the elders' idea of health as "the ability to adapt and self-manage", focusing more on social environments and ability to use resources and manage restrictions.

Association of serum uric acid with body mass index in the United Arab Emirates UAE healthy future pilot study

Mitha Balushi^{1,2}, Amar Ahmad^{2,3}, Syed Javaid⁴, Fabio Piano^{2,5}, Ayesha Dhaheer⁶, Abdishakur Abdulle¹, Fatma Al-Maskari⁷, Raghib Ali¹

¹Public Health Research Center, New York University Abu Dhabi, Abu Dhabi, United Arab Emirates, ²Institute of Public Health, College of Medicine and Health Sciences, United Arab Emirates University, Al Ain, United Arab Emirates, ³New York University Abu Dhabi, Abu Dhabi, United Arab Emirates, ⁴Department of Psychiatry and Behavioral Sciences, College of Medicine and Health Sciences, United Arab Emirates University, United Arab Emirates, ⁵New York University, Abudhabi, United Arab Emirates, ⁶Department of nutrition sciences, College of Medicine and Health Sciences, United Arab Emirates University, Al Ain, United Arab Emirates, ⁷Institute of Public Health, College of Medicine and Health Sciences, United Arab Emirates University, United Arab Emirates

Background and Objective: The UAE Healthy Future Study (UAEHFS) is the first large prospective cohort study and one of the few studies in the region which examines causes and risk factors for chronic diseases among the nationals of the UAE. Body Mass Index (BMI) has been showed to be associated with serum uric acid level in many societies. This study investigates the association of serum uric acid with BMI among the UAEHFS pilot participants.

Methods: We analyzed the UAEHFS pilot data to investigate the association between serum uric acid levels and BMI. The predictors were BMI, age, gender and age*gender using multivariate quantile regression models. The quantiles to be estimated was between 25th and 75th varied by 5th. The effect of BMI was estimated with corresponding 95% confidence interval (95% CI). Statistical analysis were performed using statistical software R.

Results: Data from 487 eligible participants (67.8% male) with a median age of 30 years (Interquartile-Range: 23-38) was used in the sensitivity analysis. Of these, 406 (83.4%) were included in the complete case analysis. The estimated effect

of BMI on the serum uric acid level in the fitted multivariate quantile regression models was positive and statistically significant. The estimated effect of BMI in the median (50th quantile) was 0.047 (95% CI: 0.033-0.070).

Conclusions: Our Results shows that higher BMI was positive and statistically significantly associated with higher serum uric acid levels. Additional research is needed, using the main UAEHFS data (after recruitment is complete), to validate this results. The main finding of this study could add to the future direction of the field of public health research.

Multimorbidity and out-of-pocket expenditure on medicine in Europe: longitudinal analysis of 13 European Health Systems between 2013 and 2015

Raffaele Palladino¹, Tianxin Pan², Stewart Mercer³, Rifat Atun⁴, Barbara McPake⁵, Fabiana Rubba⁶, Maria Triassi⁶, John Lee⁷

¹Department of Primary Care and Public Health, Imperial College of London, United Kingdom, ²Health Economics Unit, Center for Health Policy, Melbourne School of Population and Global Health, University of Melbourne, Australia, ³Centre for Population Health Sciences, The Usher Institute, The University of Edinburgh, United Scotland, ⁴Department of Global Health and Population, Harvard T H Chan School of Public Health and Department of Global Health and Social Medicine, Harvard Medical School, Harvard University, United States, ⁵Nossal Institute for Global Health, Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia, ⁶Department of Public Health, University "Federico II" of Naples, Naples, Italy, ⁷Nossal Institute for Global Health, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia

Background: Many European health systems are implementing or increasing levels of cost-sharing for medicine in response to the growing constraints on public spending on health despite their negative impact on population health due to delay in seeking care. **Objective:** this study aims to examine the relationships between multimorbidity (two or more coexisting chronic diseases, CDS), complex multimorbidity (three or more CDS impacting at least three different body systems), and out-of-pocket expenditure (OOPE) for medicine across European Nations. **Methods:** this study utilized data on participants aged 50 years and above from two recent waves of the survey of health, ageing, and retirement in Europe conducted in 2013 (n=55,806) and 2015 (n=51,237). Pooled cross-sectional and longitudinal study designs were used, as well as a two-part model, to analyze the association between multimorbidity and OOPE for medicine.

Results: the prevalence of multimorbidity was 50.4% in 2013 and 48.2% in 2015. Nearly half of those with multimorbidity had complex multimorbidity. Each additional cd was associated with a 34% greater likelihood of incurring any OOPE for medicine (odds ratio=1.34, 95% ci=1.31 - 1.36). The average incremental OOPE for medicine was 26.4 euros for each additional cd (95% ci=25.1 - 27.7), and 32.1 euros for each additional body system affected (95% ci 30.6 - 33.7). The average incremental OOPE for medicine was higher for those in the lowest socio-economic position group, as compared with those in the highest. **Conclusions:** Between 2013 and 2015 in 13 European health systems increased prevalence of CDS was associated with greater likelihood of having OOPE on medication and an increase in the average amount spent when occurred. Monitoring this indicator is important considering the negative association with treatment adherence and subsequent effects on health. This study provides additional evidence to the erosion of the universal health coverage in European health systems.

The psoriasis comorbidome

Andrea Miatton¹, Alessandra Buja², Claudia Cozzolino³, Giovanni Damiani^{1,4}, Arnon Cohen⁵

¹Università degli Studi di Padova, Italy, ²Università degli Studi di Padova, Padova, Italy, ³Istituto Oncologico Veneto, Università degli Studi di Padova, Italy, ⁴University of Milan, Italy, ⁵Clalit Health Services Israeli, Israel

Background and Objective: Psoriasis is a multifactorial, chronic, systemic inflammatory disease. Current evidence suggests that psoriasis is associated with many chronic inflammation-related morbidities, but epidemiological studies on the specific characteristics of the psoriasis comorbidome are still lacking. The aim of the present article is to compare the multi-morbidity profile between patients with and without psoriasis.

Methods: In a matched case-control study, we extracted data on 57,228 patients and 125 morbidities from the Clalit Health Services Israeli insurance database.

Psoriasis cases were matched with control individuals by sex and age at enrolment. As pre-existing comorbidities we considered all conditions already present in controls at the same age as the matched psoriasis case at the time of their diagnosis. The two-proportion Z-test was used to test for differences in the prevalence of comorbidities between the case and control groups, while logistic regression analyses were run to calculate the odds ratio (OR) for each comorbidity.

Results: A higher proportion of psoriasis patients had at least one comorbidity (70% vs. 55% approx.); and half of them had two or more comorbidities, as opposed to one in three controls without psoriasis. Judging from a prevalence analysis, more than one in four psoriasis patients already had hyperlipidemia when their psoriasis was diagnosed, while one in five had hypertension or arthropathy. Behcet's disease, hereditary neurological disorders, rheumatoid arthritis and hidradenitis suppurativa showed the strongest associations with psoriasis, with estimated ORs ranging between 3.5 and 7.

Conclusions: These findings confirmed the association between psoriasis and autoinflammatory or rheumatic diseases. Investigating the psoriasis comorbidity can help to quantify the real burden of comorbidities in psoriasis patients, and thereby support the development and adoption of personalized treatments to further improve their management.

Selenium exposure and oxidative stress and genotoxicity risk in a healthy Italian population: a cross sectional study

Teresa Urbano¹, Tommaso Filippini^{2,3}, Marcella Malavolti⁴, Bernhard Michalke⁵, Silvia Fustinoni⁶, Marco Vinceti^{7,8}

¹Environmental, Genetic and Nutritional Epidemiology Research Center (CREAGEN), Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Italy, ²Department of Biomedical, Metabolic and Neural Sciences and School of Public Health, CREAGEN - Environmental, Genetic and Nutritional Epidemiology Research Center, University of California, Berkeley, United States, ³University of Modena and Reggio Emilia, Italy, ⁴CREAGEN - Environmental, Genetic and Nutritional Epidemiology Research Center, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, ⁵Research Unit Analytical BioGeoChemistry, Helmholtz Center Munich, German Research Center for Environmental Health, Germany, ⁶University of Milan, ⁷CREAGEN - Environmental, Genetic and Nutritional Epidemiology Research Center, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Italy, ⁸Department of Epidemiology, Boston University School of Public Health, United States

Background and Objective: The relation between selenium and cellular redox status is a greatly debated topic in human health. 8-oxo-7,8-dihydro-2'-deoxyguanosine (8-oxodG) is an oxidized derivative of deoxyguanosine and a sensitive biomarker of oxidative stress and genotoxicity. The present study assessed the extent to which selenium status was associated with urinary 8-oxodG concentrations in a Northern Italian population.

Methods: Of 148 eligible subjects, 137 healthy and non-smoking blood donors living in the Reggio Emilia province during 2017-2019 were enrolled. We measured urinary 8-oxodG concentrations and used restricted cubic spline regression analyses to investigate the association between selenium status (estimated using food frequency questionnaires, urinary concentrations, and serum concentrations of selenium and selenium species) and 8-oxodG/g creatinine.

Results: Median age of our population was 48.2 years. Median urinary selenium and 8-oxodG levels (n=137) were 22.02 µg/L and 3.21 µg/g creatinine, respectively. Median total serum (n=104) concentrations were 116.50 µg/L, while median dietary intake (n=137) was 78.7 µg/day. Little association between dietary, serum, or urinary selenium with 8-oxodG concentrations emerged in the overall population. Urinary selenium positively correlated with 8-oxodG levels in men, while in women an inverted U-shaped association emerged. Total organic selenium and selenoprotein P levels were positively associated with 8-oxodG until 100 µg/L and then the association became slightly inverse in both sexes. In males, glutathione peroxidase-bound selenium and selenomethionine were positively correlated with 8-oxodG, while negative associations emerged for inorganic species. In females, positive but weak associations emerged for organic selenium species.

Conclusions: Results of our study suggest that even though total selenium exposure seems not associated with 8-oxodG, selected selenium species may largely differ in their association with this oxidative stress biomarker, and that effects modification by sex was encountered. Selenomethionine-bound selenium was the organic compound most strongly associated with 8-oxodG.

Key considerations for the implementation of active assisted living systems to support older adult care

Gaya Noon¹, Thoko Phiri¹, Laura Fadrique¹, Jennifer Teague², Plinio Morita¹

¹University of Waterloo, Canada, ²CSA Group, Canada

Background and Objective: Active Assisted Living (AAL) refers to internet-connected systems designed to improve quality of life, aid in independence, and create healthier lifestyles. As the population of older adults grows, there is a pressing need for additional supports in their daily lives and for non-intrusive, continuous, adaptable, and reliable health monitoring tools. AAL has great potential to support these efforts, but additional work is required to address the feasibility of the integration of AAL into care. The objective of this project is to address core issues with AAL system implementation, including user concerns, data governance, and building requirements for smart living environments.

Methods: To understand the concerns and opportunities regarding AAL, as well as to validate our data governance framework, 18 semi-structured group interviews were held with stakeholders representing different parts of an AAL ecosystem. Each group comprised of several participants from the same organization. These were categorized as (1) care organizations, (2) technology developers, (3) technology integrators, and (4) potential care recipients or patient advocacy groups. Furthermore, a review of 156 smart home technologies was conducted to understand what their technical requirements are and what issues may be faced by users trying to implement them.

Results: There is a critical need to acknowledge the trade-off inherent in AAL use between the benefits of the technology, their encroachment on privacy, and their cost in terms of time and finances. This trade-off is influenced by several factors, including the care context and what resources care recipients have available to them.

Conclusions: A greater consistency in oversight is needed, including clearer definition in roles and who can access and is responsible for acting on data from AAL systems. Further work is necessary to address these needs, as well as set standards for AAL technologies and explore the equity of AAL access.

Importance and determinants of advance directives and healthcare proxy use among the oldest-old

Judith Wenner¹, Ferzaneh Fakdani¹, Susanne Zank¹

¹University of Cologne, Germany

Background and Objective: Making advance directives or deciding on a healthcare proxy are common instruments to assure that end-of-life care is in line with one's own wishes. Correctly specified, these instruments help health professionals and relatives to act in the best interest of the patient. We use two large population-based datasets from Germany to explore if the oldest-old (80+) make use of these instruments and what determines this use.

Methods: Analyses are based on two population-based studies among persons aged 80 years and older in Germany. We perform descriptive and subsequently logistic regression analyses to identify who makes use of these instruments. In line with theoretical assumptions on healthcare behavior, we consider age, gender, education, (functional and cognitive) health, institutionalization, social embeddedness, and personal attitude (towards spirituality, assisted suicide and death) as determinants of using advance directives or deciding on a healthcare proxy.

Results: The majority in both studies had either advance directives or decided on a care proxy (76.2% and 87.4%). Often participants used both (62.8%). In the large nation-wide sample, higher age, good functional health, a partnership, and a strong focus on self-determination at the end of life increased the odds of using these instruments while cognitive impairment decreased their use. In the smaller regional sample, only cognitive impairment was significantly associated with (lower) use.

Conclusions: Most persons aged 80 years and older in Germany make use of advanced directives and decide on a healthcare proxy. This shows that the oldest-old want to have a say in their end-of-life care and want their alleged wishes to be considered. Persons with cognitive impairment – and thus potentially in need of these instruments – had considerably lower odds of using them. Targeted information for persons with beginning cognitive decline within the healthcare setting could thus be helpful.

Transition to retirement impact on depressive symptoms: results

from a longitudinal analysis within the Survey of Health, Ageing and Retirement in Europe (SHARE) project

Giacomo Vigezzi¹, Giacomo Vigezzi¹, Giansanto Mosconi¹, Paola Bertuccio¹, Andrea Amerio², Anna Odono¹

¹Department of Public Health, Experimental and Forensic Medicine, Università degli Studi di Pavia, Italy, ²Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), Università degli Studi di Genova, Italy

Background and Objective: In an ageing society, with people living long years after retirement, pension impacts on mental health outcomes should be carefully assessed. Scant evidence is available from longitudinal studies on the short and long-term impact on depressive symptoms and suicidal ideation.

Methods: We conducted a longitudinal study based on the Survey of Health, Ageing and Retirement in Europe (SHARE) data from 28 European countries collected between 2004 and 2020. To estimate the relative risk (RR) and corresponding 95% confidence intervals (CI) for depression (derived from the EURO-D scale as a binary outcome) and suicidality at seven different time intervals since retirement, we fitted generalised estimating equation models for repeated measures.

Results: We selected a cohort of 8,998 individuals employed at baseline and retired at follow-up (median follow-up time: 9 years; maximum: 16 years). Considering the "year of retirement" as the reference category, the risk of depression ten years or more before retirement resulted being about 17% higher (RR: 1.17; 95%CI: 1.03-1.32), with a trend to decrease - tough estimates were not statistically significant - as retirement approached. Compared to the year of retirement, we observed a 9% (RR: 0.91; 95%CI: 0.82-1.00) to 11% (RR: 0.89; 95%CI: 0.81-0.99) reduction in risk in the following three years, and a gradual rise thereafter. Because their risk patterns did not overlap, suicidality and depression stood out as clinical entities that do not necessarily cooccur and require different preventive strategies.

Conclusions: Longitudinal data suggest that transitioning to retirement reduces the risk of depression in the first years after the withdrawal from work, in the so-called honeymoon phase. As retirement seems to have an independent and protective effect on mental health, it may be identified as a target moment for preventive interventions to promote well-being in older ages and boost the observed impact.

Developing new models for integrated community health and social care for dependent older people: the case of Programa Maior Cuidado in Brazil

Karla Giacomini¹

¹Oswaldo Cruz Foundation (Fiocruz), Brazil

This paper offers a case study of the development, implementation, evaluation and national scale-up of a novel intervention for dependent older people living in vulnerable families. It also identifies key lessons for other countries facing similar health service challenges. Since 2011 Programa Maior Cuidado (PMC) has been supporting care-dependent older people living in poor neighbourhoods of Belo Horizonte. Local health posts and social assistance centres work together to identify eligible families and provide integrated support. Trained paid family-support caregivers, recruited from similar communities, provide families 10 to 40 hours of help a week. This offers family caregivers respite from round-the-clock care-work, and PMC carers also promote family care-giving skills. PMC carers monitor older people's condition and report back to monthly case reviews jointly conducted by staff at health and social assistance posts. Over the past five years, there have been an ongoing process and impact evaluation of PMC, including both before and during the COVID-19 pandemic. These have generated broadly positive findings, including evidence that PMC is cost effective, promotes more effective use of health services and benefits both older people and their families. This has led the Ministry of Health to support PMCs national roll-out, and PMCs identification as a model of best practice by WHO, World Bank and other agencies.

Patient-reported outcomes in robotic total knee arthroplasty: a retrospective cohort study with Robotic Surgical Assistant system

Daniele Ceriotti¹, Matteo Ratti¹, Rabia Bibi², Riccardo Rescinito¹, Massimiliano Panella¹

¹Università del Piemonte Orientale, Italy, ²Università del Piemonte Orientale, Pakistan

Background and Objective: Even if RATKA (Robotic assisted total knee arthroplasty) is a widely used surgery, there is still a gap of knowledge about patient reported outcomes. The aim of this study was to compare self-reported

outcomes in patients who underwent RATKA (with ROSA - "Robotic Surgical Assistant system"- technique) and patients who underwent the manual surgery (traditional technique).

Methods: We compared 73 patients operated with ROSA technique with 62 operated with traditional technique. The data were collected with WOMAC (Western Ontario and McMaster University Osteoarthritis index), a self-administrated questionnaire that investigates pain, stiffness, and functionality of the patients. We performed two surveys, the first was before the intervention and the second was 6 months after the surgery. We evaluated the absolute and percentage differences between the two groups. Statistical analysis were performed with two-tailed T-test and chi-squared test.

Results: After the 6 months follow-up, we observed lower PROM scores in both groups. In particular, the total WOMAC score in the ROSA group dropped from 66.0 to 32.5, while in the other group it decreased from 62.4 to 24.6. The post-operative absolute difference between the WOMAC scores of two groups was 7.9 points (95%CI: -12.49 to -3.23) in favor of conventional technique. On the other hand, the analysis of the percent improvement, despite still slightly in favor of the conventional group (54.1% vs 47.8%), failed to reach statistical significance (p=0.23). The post-operative percentage difference was 6.3% (95%CI: -4.0% to 16.7%).

Conclusions: These findings indicate that a clear superiority of RATKA to conventional TKA is not yet demonstrated. Moreover, a knowledge gap about the proper methodology to analyze the patient reported outcome measures may exist. Also, given the recent evolution of the technology, an urgent need to conduct studies with longer term outcome evaluation is compelling.

Empowerment of healthy ageing through integrated care managers in China

Ninie Wang¹

¹Pinetree Care Group, Chaoyang District, China

With over 200 million people over the age of 65 by the end of 2021 and around 50 million being care dependent, China faces the enormous challenge of reforming the system and strengthening primary health care to meet the needs of older adults, aiming for better prevention and reduction of care dependency as part of the nation's healthy ageing strategies. While people-centered integrated care (PCIC) has been set as the key model for improving the health and care systems in coming decades, World Health Organization's ICOPE (integrated care for older people) is being implemented first in Beijing, then in a multi-center pilot across China. Health and social care workers went through modular training sessions before becoming "integrated care managers" to carry out screening, assessment and care plans in primary care settings following the ICOPE care pathways that are adapted to fit locally available resources. Incentives are designed for them to receive additional income and recognition from delivering personalized care plans. Despite their heavy duty of pandemic control-related tasks, primary health care workers reported high levels of satisfaction and interest in continuing as the front-line providers of integrated care, supported by multi-disciplinary teams from hospitals, nursing care and higher education institutions. Coordinated teams leveraged tele-care tools to empower each other when working against the risks of intrinsic capacity decline and functional ability loss among community and home-dwelling older adults. The ICOPE implementation pilot in China might provide some reference for feasibility and impact of integrated care on the health and social well-being of the ageing population in low resource settings. Advocating a policy shift from disease-oriented approach to one that promotes holistic care continuum often demands locally relevant and applicable innovations.

Predictors of Chronic Pain: comparison between older adults with and without life-long cognitive disability

Rafat Hussain¹, Stuart Wark², Trevor Parmenter³, Matthew Janicki⁴

¹School of Medicine and Psychology, Australian National University, Canberra, Australia, ²School of Rural Medicine, University of New England, Armidale, Australia, ³Centre for Disability Studies, University of Sydney, Australia, ⁴University of Illinois, United States

Background and Introduction: Chronic pain is a major public health issue globally, adversely affecting quality of life (QoL) of older adults. It constitutes a 'silent epidemic' in many countries including Australia. Amongst those with life-long cognitive impairments, are people with intellectual disability (PwID), who experience multiple socioeconomic and health disadvantages. This comparative study aims to examine concurrent underlying social and health factors as predictors

of chronic pain in older PwID cohort compared to their normative age peers (i.e. older non-PwID cohort). Methods: Data were derived from cross-sectional surveys on demographic, socioeconomic, health and health-services measures across Australia's two most populous states – New South Wales and Queensland. The sample included older adults aged 60+ years (PwID, N=391; non-PwID=920). The PwID cohort required face-to-face interviews to mitigate comprehension-limitations that could confound results. Non-PwID cohort completed paper/online survey forms. No observable errors were found in response validity by variation in survey modality.

Results: PwID cohort was younger (mean: 65.2y, SD: 4.4y) compared to non-PwID (mean: 71.9y, SD: 7.7y). Chronic pain was reported by both PwID (26.9%) and non-PwID (24.1%) groups. Univariate logistic-regression for both cohorts showed chronic pain to be associated ($p < 0.05$) with arthritis, gum disease, falls, and sleep-disturbance, whereas cancers (past & current) were not significantly associated. Anxiety, depression, and adverse life-events were also statistically significant. Multivariable regression modelling showed that significant variables ($p < 0.05$) for PwID cohort included arthritis and adverse life-events, whereas for the non-PwID cohort arthritis, falls, adverse life-events, and depression were significant. Conclusions: Despite its relatively younger age-profile, PwID cohort had higher levels of chronic pain. There was also similarity of factors associated with chronic pain in both cohorts. The presentation will highlight importance of better understanding and managing predictors of chronic pain for maintaining or enhancing quality of life of older adults.

Development and validation of a dietary diversity score for French older adults

Anne-Fleur Jacquemot¹, Rosalie Prat², Rozenn Gazan², Christophe Dubois³, Nicole Darmon⁴, Catherine Fearth⁵, Eric Verger⁶

¹INSERM, BPH, UMR1219, F-33000, Université de Bordeaux, Bordeaux, France, ²MS-Nutrition, Marseille, France, ³Trophis, France, ⁴MoISA, University Montpellier, CIRAD, CIHEAM-IAMM, INRAE, Institut Agro, IRD, Montpellier, France, ⁵Inserm, France, ⁶MoISA, Univ Montpellier, CIRAD, CIHEAM-IAMM, INRAE, Institut Agro, IRD, Montpellier, France

Adopting healthy dietary habits, including higher dietary diversity, has been associated with healthy aging. Several scores have been developed to assess the dietary diversity, but none specifically among older adults. Therefore, the present work aimed to develop and validate a healthy dietary diversity score (DAS) in a sample of older adults enrolled in a representative national survey. The studied sample was constituted of 696 older adults aged 60y and over, from the latest cross-sectional French Individual and National Food Consumption study (INCA3). The dietary survey included three 24 hours recalls and a Food Propensity Questionnaire. The occurrence of consumption of 20 food groups weighted by positive (for whose consumptions are healthy and should be encouraged) or negative (for whose consumptions are unhealthy and should be limited) points composed the 20 score components whose sum defined the DAS. The validity of the DAS was assessed by describing its association with the food score components, energy intake, solid energy density (SED), probability of adequate nutrient intake assessed by the PANDiet and with educational and physical activity levels. The DAS ranged from -35 to 115. Higher DAS were positively and significantly associated with more points in healthy score components like Fruits or Vegetables ($r = 0.51$, $p < 0.0001$ and $r = 0.54$, $p < 0.0001$ respectively). The DAS was not significantly associated with the total energy intake ($r = 0.02$, $p = 0.6$). The DAS was significantly positively associated with the PANDiet ($r = 0.43$, $p < 0.0001$) while inversely associated with the SED ($r = -0.37$, $p < 0.0001$). Higher DAS were observed among participants with higher educational and physical activity levels as expected. The DAS we developed is validated to assess the healthy dietary diversity score of French older adults. Beyond, it could be a useful tool to assess the impact of public health nutritional trials.

DOI: 10.18332/popmed/165588

Association of pain and depression among middle-aged and older adults of India

Amit Goyal¹, Amit Goyal¹, Sanjay Mohanty¹

¹International Institute for Population Sciences, Mumbai, India

Background and Objective: India is ageing and it is estimated that the population age 45 and above will account over 40% of the population by 2050. Ageing is associated with high burden of chronic diseases. Approximately one third of the population aged 45+ are also suffering from pain and depressive symptoms. Epidemiological studies have shown that pain and depression are closely related.

We didn't find any nationally representative study establishing this relationship of pain and depression. This study aims to examine the association between pain and depression among middle-aged and older adults of India.

Methods: This study uses the individual level data from the Longitudinal Ageing Survey of India (LASI), Wave 1, 2017-18. This study is restricted to 59416 individuals who have responded to all the variables of interest. We used the Center for Epidemiologic Studies Depression (CES-D) Scale short form to measure the depression with threshold of ≥ 4 symptoms. Pain is measured by a polar question i.e. "Are you often troubled with pain?". Descriptive statistics were reported by proportions or mean. Independent chi-square tests were used to compare the categorical variables between those with and without pain and depression. The estimates for the prevalence of depressive symptoms were adjusted for age-sex considering the national age and sex composition as reference. The logistic regression model was used with depression as outcome variable and pain and socio-demographic covariates as predictor variables.

Results: Depression typically affects 25% of the middle aged and older adults without pain, but among patients with pain, 32% experience depression. The predicted probability of depression among those with pain was 0.31 compared to 0.25 among those without pain. Considering the older adults with pain, there is huge variation in the prevalence of depression among states of India ranging from 56.5% in Jammu and Kashmir to 8.8% in Mizoram. This will be done via SLIDO and via personal interventions of the delegates. Also, delegates from public bodies and from academic institutions will be invited to attend and actively contribute to improve cross-country exchange and learnings in population health from a planetary perspective. The integrated pathways of care in the social and healthcare services: the AgICOT experience in Teramo, Italy

Marco Del Riccio¹, Stefano Greco², Valerio Profeta², Chiara Lorini¹, Niccolò Persiani³, Santa Remigis⁴, Guido Angeli⁵, Dimitrios Kaliakoudas⁶, Eleonora Sparvieri⁷, Guglielmo Bonaccorsi¹, Martina Giusti⁸, Patrizio Zanobini¹, Maurizio Giosia⁸

¹Department of Health Sciences, University of Florence, Italy, ²Department of Community and Territorial Services, Local Health Unit of Teramo, Italy,

³Department of Experimental and Clinical Medicine, University of Florence, Italy, ⁴Anesthesia and Intensive Care, Teramo Hospital, Local Health Unit of Teramo, Italy, ⁵Medical Direction, Teramo Hospital, Local Health Unit of Teramo, Italy, ⁶Counselling Center, Local Health Unit of Teramo, Italy,

⁷Internal Medicine, Teramo Hospital, Local Health Unit of Teramo, Italy, ⁸Local Health Unit of Teramo, Italy

Background and Objectives: The process of population ageing leads to greater needs for local welfare services. This projects main Objective is to strengthen the hospital-territory integration by establishing Hospital - Territory Agencies of Continuity and Integration (AgICOT) in the Local Health Unit (ASL) of Teramo. The specific target of the project is frail elderly people aged 65 years or more.

Methods: A multidisciplinary working group (health professionals from the Local Health Unit of Teramo and academics from the University of Florence) has set up an organizational plan and a training course for all the health professionals working in AgICOT. The innovative tools used by AgICOT are the Life Project (LP), a document that collects clinical, social, psychological, and linguistic-communicative assessments of the followed person, and the Healthcare Budget (HB), which is the sum of all healthcare, social and relational resources and services used for this person. Individuals followed by AgICOT are monitored and/or re-evaluated continuously, and LP and HB are updated in each of these situations.

Results: Between April and October 2022, the working group defined the organization of AgICOT and its kick-off, and at the same time prepared and implemented a training course on the topics of primary care and transition care management. The first AgICOT was inaugurated in October 2022 and started working on 20 cases, which represent the first group of patients served by the new Agency.

Conclusions: AgICOT takes care of the frail elderly by defining a care pathway that is comprehensive of both social- and health-related aspects. The re-evaluations and continuous monitoring guarantee that every need is better assessed and can find a proper answer outside the hospital. AgICOT will not only improve the integration between the hospital and the territorial services, but it will also improve an effective and efficient use of the latter.

Gender differences in global Disability-Adjusted Life Years (DALYs): a descriptive Analysis of the global burden of disease study 2021

Vedavati Patwardhan¹, Luisa Flor¹, Emanuela Gakidou²

¹Institute for Health Metrics and Evaluation (IHME) University of Washington, Seattle United States, ²Institute for Health Metrics and Evaluation (IHME)

Background & Objective: Gender inequalities in society result in gender differences in the social determinants of health and health risk factors, and have lifelong health consequences. However, little research systematically examines the magnitude and nature of gender differences in health across the life course.

Methods: We used data from the Global Burden of Disease Study (GBD) 2021 to conduct a descriptive analysis of gender differences in the top-20 causes of male and female Disability-Adjusted Life Years (DALYs) globally and across world regions for four age groups (10-24, 25-49, 50-69, and 70+ years).

Results: Across the lifespan, female DALY rates are higher than males ($p < 0.05$) for mental, neurological, and musculoskeletal disorders globally. For depressive, anxiety, and headache disorders, the female-male gap emerges at an early age and continues over the life course. The gender gap in low back pain widens with age and is highest at 70+ years. Girls and women aged 10-49 years have higher DALYs due to HIV/AIDS compared to men, and the most pronounced gap is in sub-Saharan Africa. On the contrary, for several conditions with a higher male burden ($p < 0.05$), gender gaps emerge after 50 years, for e.g., for COVID-19, ischemic heart disease, and lung cancer. Among younger males (10-24 years), road injuries are the top cause of global DALYs, with the largest male-female gap in Latin America. We also find that women and girls are more affected by conditions with a higher morbidity burden throughout their lifespan. On the other hand, men and boys of all ages bear a disproportionate mortality burden.

Conclusions: Our study highlights the need for policy interventions to promote well-being and reduce gender disparities in health at all stages of life, in line with the United Nations Sustainable Development Goals (SDGs) 3 and 5.

Reliability and validity of the bone health literacy questionnaire for middle-aged and elderly women

Biao Xu¹, Chenyang Jin¹, Yuge Zhang¹, Hong Jiang¹, Biao Xu¹

¹Fudan University China

Objective: To develop a questionnaire for assessing bone health literacy among perimenopausal and postmenopausal women in Shanghai, and to evaluate reliability and validity of the questionnaire and to provide scientific evidence for generalizing the application of the questionnaire in the elderly. **METHODS** The questionnaire was developed based on the integrated theoretical model of health literacy proposed by Regional Office for Europe of World Health Organization in 2012. Using relevant questionnaires in domestic and abroad literatures for reference, through two rounds of expert consultation, 45 items of bone health literacy questionnaire were formed. After evaluating the repeatability and effectiveness of the questionnaire, a questionnaire on bone health literacy for middle-aged and elderly women was formed. 40 items of bone health literacy questionnaire for perimenopausal and elderly women were summarized. Cronbach's α and split-half reliability were calculated to evaluate the reliability of bone health literacy questionnaire, and content, discriminant, convergent and structural validity were performed to measure the validity of the questionnaire. **RESULTS** A total of 447 community women aged 45-65 were investigated. The overall Cronbach's α of bone health literacy questionnaire was 0.763 and the split-half reliability was 0.793. The correlation coefficient of each sub-questionnaire with the total questionnaire was 0.403~0.703. The bone health literacy questionnaire had good content validity, with the success rate of calibration experiment of 57.50% and 86.25% respectively. Confirmatory factor analysis showed that the goodness of fit index (GFI) and other indicators reached the adaptation standard, and the structural validity was good. **Conclusion:** The questionnaire has good reliability and validity, and can be used as a simple tool to measure and evaluate bone health literacy.

Serological responses up to 9 months following COVID - 19 mRNA vaccination in residents and healthcare workers of long - term care facilities: a multicenter prospective cohort study in Northern Italy

Valerio Bordino¹, Costanza Vicentini¹, Alessandro Cornio¹, Noemi Marengo¹, Davide Meddis¹, Jacopo Garlasco¹, Savina Ditommaso¹, Monica Giacomuzzi¹, Carla Zotti¹, Gabriele Memoli¹, Maria Gianino¹

¹Università di Torino Italy

Background and Objective: Long-term care facilities (LTCFs) were severely affected by COVID-19, in particular in Northern Italy. We aimed to assess antibody responses among residents and healthcare workers (HCWs) of 13 LTCFs through serum samples collected at three time points: prior to, two weeks, and 9 months after receiving Pfizer/BNT162b2 SARS-CoV-2 mRNA vaccine (respectively t0, t1, and t2).

Methods: IgG antibodies targeted towards the S1 domain of the spike protein were measured, and results were expressed in binding antibody units (BAU/ml). Friedman's average rank test was performed to compare antibody titres between the three time points. Two logistic regression models were built to identify independent predictors of (1) developing and (2) maintaining a significant antibody response to vaccination, using a previously identified threshold. In total, 534 subjects were enrolled (371 HCWs and 163 residents).

Results: Age had a bi-modal distribution, in line with participant type: the median age among HCWs was 47 years (IQR 38 - 54), and was 86 years (IQR 80 - 90) among residents. The majority of participants were female, both among HCWs and residents (83.01 and 70.55% respectively). Over half of study participants had a SARS-CoV-2 infection confirmed by RT-PCR prior to t0, however the proportion of seropositive individuals at t0 was 37.83%. The antibody titres at t1 were the highest; at t2 the IgG titres significantly decreased, remaining however 10 times higher compared to titres at t0. Previous infection was the only significant predictor of developing and maintaining a response over threshold in both models. Residents showed higher IgG titres than HCWs at each time point. Significant differences were found at all time points stratifying participants according to age.

Role of vegetarian and plant-based diet in the prevention of mild cognitive impairment and dementia

Giulia Barbolini¹, Giulia Barbolini¹, Marco Vinceti¹, Tommaso Filippini¹

¹University of Modena and Reggio Emilia, Italy

Background and Objective: The increasing number of people with Mild Cognitive Impairment (MCI) and dementia represents a relevant public health problem. For this reason, there is interest in the assessment of factors affecting disease risk, in order to implement effective prevention strategies and promote a healthy lifestyle. In particular, diet as a determinant of cognitive impairment and dementia represents an important field of research, and many studies focused on the effects of plant-based, vegetarian or vegan diets on cognitive functions and dementia risk.

The aim of this systematic review is to assess whether a plant-based or a 'strict' vegetarian diet is protective or detrimental towards cognitive functions.

Methods: The protocol of this systematic review and meta-analysis has been submitted to PROSPERO. The literature search has been conducted on 4 different databases: PubMed, Web of Science, Embase and Cochrane library. We used MeSH terms and keywords related to "plant-based diet", "vegetarian diet", "Mild Cognitive Impairment", "dementia" and "memory impairment". We found 2 additional articles through citation chasing techniques.

We defined the following inclusion criteria according to the PICOS statement: adult population, adherence to plant-based, vegetarian or vegan diets, assessment of cognitive functions through dementia risk or cognitive decline at increasing adherence to different dietary patterns, and both observational studies (cohort, cross-sectional or case-control) and randomized clinical controlled trials. We will also perform a dose-response meta-analysis whenever possible.

Results: In the preliminary literature search, we found a total of 1537 articles (including 2 studies added through citations), 255 of which were duplicates. After duplicate removal, the abstract and the full-text of 1282 articles were screened, leading to the exclusion of 1263 of them. Nineteen studies met our inclusion criteria and could be included in the systematic review.

Conclusions: The study is currently ongoing and its results will be presented at the Congress.

Do meta-analyses of randomized controlled trials estimate the true population effects of multiple risk factor interventions?

Mark Speechley¹, Saverio Stranges¹, Manuel Montero Odasso¹, Paige France²

¹Western University, Department of Epidemiology & Biostatistics, Western Centre for Public Health & Family Medicine, 1465 Richmond Street, London Ontario, N6G 2M1, Canada, ²University of Toronto Mississauga, Studies in Life Sciences Program, 3359 Mississauga Rd., Mississauga Ontario, L5L 1C6, Canada

Background: Large reductions in cardiovascular disease (CVD) mortality since 1950 are a significant public health triumph. Explanatory models of declining CVD mortality trends in high-income countries attribute just under 50% each to population trends in medical/surgical interventions and risk factor reductions, leaving <10% unexplained. However, meta-analyses (MA) of multifactorial trials yield modest effect sizes that explain only a tiny fraction of the population declines. Arguably, entire population data are superior to MAs of Randomized Controlled Trial (RCT) samples given the methodological and practical problems of experimentally estimating the effect of simultaneously modifying several factors in real-world settings. Might MAs of multifactorial RCTs also underestimate the true population effects of multiple risk factor modifications in other common outcomes in older adults?

Methods: For cognitive impairment (CI) and unintentional falling (UF) in older adults, literature searches were conducted for i) MAs of multifactorial RCTs and ii) attempts to explain population trends in terms of changes over time in risk factors and clinical interventions.

Results: For UF, while some well-done RCTs show clinically significant comparative reductions in both fall occurrence and the number of risk factors in intervention groups, MAs tend to show modest or even null results. While fewer multifactorial RCTs have been completed for CI, early MAs also show modest effects. No attempts were found to replicate the CVD trend analysis for UF or CI, possibly because neither UF nor CI outcomes, or trends in risk factors or clinical interventions, are available in population data like for CVD. This data incompleteness might be overcome with statistical models that interpolate partial time-series data from numerous sources to estimate the true population effects of multifactorial interventions.

Conclusion: Estimating the true population effects of UF and CI interventions may require more sophisticated methods than MAs of samples studied in complex and problematic multifactorial RCTs.

Assessing the quality of the built environment in dementia: a framework to evaluate long-term care facilities

Silvia Mangili¹, Silvia Mangili¹, Gaia Ferraguzzi², Stefano Capolongo¹

¹Politecnico di Milano, Italy, ²Università degli Studi di Milano Statale

Introduction: Life expectancy worldwide is raising fast, with a correlated increase in Non-Communicable Diseases (NCDs) and years lived with disability. Dementia is one of these, with about 7 million people affected in Europe and the number is set to double by 2050. These patients are complex due to the serious changes in the cognitive sphere, altering perceptions of the space. They are the most frequent users of healthcare facilities, but these structures often are not suitable for them. For this reason, rethinking is now urgent to create safe and suitable environments. **Materials and Methods:** This study aims to develop an evaluation framework of the main aspect of the design of a built environment for people with dementia.

To this end, a systematic literature review has been conducted on scientific databases using meaningful keywords. The review was useful to outline the main characteristics that the environment dedicated to the dementia patient must possess to be inclusive and prosthetic.

Results: The research has allowed defining a set of requirements that the space must have to be prosthetic for the patient. These findings have been identified and were divided into three main macro-areas (physical, cognitive, and social aspects) 7 criteria, and 31 related sub-criteria. The results were also validated through the involvement of stakeholders and experts in the topic, both from the architectural and medical field to establish the relationship between physical factors and patient outcomes.

Conclusion: The results of this research can be used as guidelines to assess and design proper facilities for people with dementia and cognitive disabilities. This is because there is an urgent need to create and renovate the existing buildings to make them as therapeutic and prosthetic as possible. The priority also in research must be to investigate which aspects of architecture can impact patients' health and well-being.

Longitudinal clustering of health behaviours and their association with health outcomes in older adults in England: a latent class analysis

Alisha Suhag¹, John Holmes², Thomas Webb¹

¹Healthy Lifespan Institute, University of Sheffield, United Kingdom, ²School of Health and Related Research, University of Sheffield

Background: Leading risk factors for chronic disease – smoking, alcohol

consumption, poor nutrition and physical inactivity (SNAP behaviours) – cluster together (i.e., appear in specific combinations in distinct subgroups). Longitudinal clustering and its association with health outcomes are less well understood.

Objective: This is the first study to identify longitudinal clusters of SNAP behaviours and to relate them to health outcomes in older adults.

Methods: Using data from Waves 4-8 of the English Longitudinal Study of Ageing (n=3787), we identified longitudinal clusters of SNAP behaviours using latent class analysis. Health outcomes (from Wave 9) included multimorbidity and complex multimorbidity, along with eight body system disorders defined according to the International Classification of Diseases 10th Revision system. To examine how clusters are associated with socio-demographic characteristics and health outcomes, we used multinomial and binomial logistic regressions, respectively.

Results: Six clusters with stable within-cluster behaviour trajectories were identified: Low-risk (20.9%), Low-risk but heavy drinkers (11.1%), Low-risk but inactive (22.2%), Do nothing (17.2%), Inactive, heavy drinkers (18.1%), and High-risk smokers (10.5%). Health-risk dominant clusters had lower levels of education and wealth. Women dominated the Low-risk but inactive cluster, whereas men dominated the heavy drinking clusters. Low-risk and Low-risk but heavy drinkers had a lower prevalence of all adverse health outcomes compared to other clusters. In contrast, the Low-risk but inactive cluster had the most 'negative' outcomes: highest prevalence of multimorbidity, complex multimorbidity, circulatory disorders, and endocrine, nutritional and metabolic disorders. High-risk smokers were most likely to suffer respiratory disorders, while the least physically active clusters were most likely to suffer endocrine, nutritional, and metabolic problems. **Conclusions:** Health behaviour clusters were strongly but differentially associated with health outcomes, suggesting a complex relationship. Identified clusters can be compared with similar analyses in other countries and used to tailor interventions to specific sub-populations and socio-demographic profiles.

Suffering in Silence: Urinary Incontinence among Bangladeshi Women

Quamrun Nahar¹, Anadil Alam¹, Farah Rahman¹, Shusmita Khan², Mizanur Rahman³

¹icddr,b, Head of Research, 68 Shahid Tajuddin Ahmed Sharani, Mohakhali, Dhaka 1212, Bangladesh, ²Data for Impact, University of North Carolina, Research Associate, "Chapel Hill, Chapel Hill, NC, USA, Based at 68 Shahid Tajuddin Ahmed Sharani, Mohakhali, Dhaka 1212, Bangladesh", Bangladesh, ³Data for Impact, University of North Carolina

Background and Objective: Urinary incontinence (UI), the involuntary loss of urine, is a common, distressing condition of women, affecting all ages and across different cultures. Globally, an estimated 200 million women suffer from UI, although the prevalence of UI varies across settings. Research on UI has primarily been conducted in developed countries and there is a paucity of data on UI in developing countries. The objective of this paper is to provide an estimated prevalence of UI, its sub-types and associated factors among ever-married women aged 15-49 years in Bangladesh.

Methods: This paper used data from 2016 Bangladesh Maternal Mortality and Health Care Survey, conducted in a nationally representative sample of 300,000 households. Ever-married women aged 15-49 years, residing in these households, who had ever given birth were asked a set of pre-tested questions to identify symptoms of stress and/or urge incontinence. The weighted prevalence of UI, its sub-types, and factors associated with different types of UI were identified using logistic regression. All analyses were conducted in Stata version 15.

Results: The prevalence of any UI was 15.8% (95%CI 15.7, 16.0). The most common subtype was stress incontinence, with a prevalence of 13.7% (95%CI 13.5, 13.8), followed by urge incontinence, with a prevalence of 7.6% (95%CI 7.5, 7.8) and mixed incontinence, with a prevalence of 5.5% (95%CI 5.4, 5.6). Age, religion, parity, educational attainment, economic status and residence in certain parts of Bangladesh are the risk factors for women's reporting of different types of UI. **Conclusion:** The study findings are in line with findings from other South Asian country studies. The findings of this study, with its large sample size, population-based sampling and rigorous data collection process, will be useful for making effective plans to reduce the silent sufferings of Bangladeshi women from UI.

Health outcomes and physiological adaptations of regular physical activity among young individuals

Marta Wilhelm¹, Rita Soós¹, Ádám Gyebrovski², Kitti Garai¹, Zoltán Ádám¹, Monika Gordos³, Krisztián Kvell¹

¹University of Pécs, Institute of Sport Sciences and Physical Education, University of Pécs, Faculty of Sciences, Pécs, "Ifjúság u. 6., 7624 Pécs, Hungary", ²Doctoral School of Biology and Sportbiology, ³University of Pécs Regular Physical activity (PA) is important counteracting decline of physiological and molecular parameters in elderly, while among younger age groups it is also crucial maintaining proper age matched physical fitness. According to WHO physical inactivity is one of the most important causes of deaths and long-lasting sicknesses.

The aim of our study was to measure biological effects of regular PA among young healthy adults. Previously inactive individuals, 20-25 years old females (N= 18) enrolled in a six-month exercise program conducted by a personal trainer. During the study 60 min complex exercises were conducted, 3x/week, average time 180 min/week. Intensity of strength training and aerobic exercise was calculated with HRmax, regularly adjusted to the actual fitness of participants.

Field and laboratory tests (body composition, cardiovascular parameters, 6MWT, activity measurements) were applied determining health-related physical fitness. Immune (cortisol, CRP, lymphocytes, hTREC) and metabolic parameters (glucose, insulin, HDL, LDL) were assessed from blood samples.

Body composition, cardiovascular, metabolic and immune parameters showed improvement. After 3 months of training mostly blood parameters changed and correlated significantly, while after 6 months many hormonal and metabolic changes were found in the whole population. Correlation of CRP-CK (P=0.036) was found, CRP-Insulin (P=0.033), WBC-Glucose (P=0.046), Monocytes correlated with RDW (P=0.046), Monocytes-Glucose (P=0.028), Monocytes-MPV (P=0.015). Glucose correlated with MPV (P=0.037), with Biceps (P=0.042), Triceps (0.013). BF% and Muscle mass% (P=0.001) has a strong correlation at each measured time point, just like Cortisol-Insulin levels after sixth months of training (P=0.000). Muscle mass% and BF% (P=0.000) are strongly correlated, insulin level correlated parameters of body composition, muscle mass% (P=0.002), Bodyfat% (P=0.010), and Subscapula (P=0.029). Cortisol-Biceps (P=0.005) correlation was also found. Data show that moderate regular PA is essential to counteract senescence of metabolism and early regression of fitness in young, healthy individuals, becoming the basis of healthy ageing.

The role of the built environment in dementia: evolution and adaptation of an innovative care model through the SARS-CoV-2 pandemic

Gaia Ferraguzzi¹, Mariella Zanetti², Paolo Mazzola³, Maria Sandrini², Fulvio Sanvito², Rosetta Gagliardo⁴, Antonio Colaiani⁵, Catia Borriello⁴, Danilo Cereda⁴

¹Università degli Studi di Milano Statale, Dipartimento di Scienze Biomediche per la Salute, Università degli Studi di Milano Statale, Milano, Italy, ²Cooperativa La Meridiana, Italy, ³Università degli Studi Milano Bicocca, School of Medicine and Surgery, Università degli Studi di Milano-Bicocca, Monza (MB), Italy - Acute Geriatrics Unit, San Gerardo Hospital ASST Monza, Monza (MB), Italy, ⁴Regione Lombardia, DG Welfare, Regione Lombardia, Milano, Italy, ⁵ATS Brianza

Introduction: The first Alzheimers village in Italy rises in Monza named "Il Paese Ritrovato", an innovative long-term care facility dedicated to individuals with mild-to-moderate Alzheimers disease or other Dementias. The total area is 3,360 m² and it hosts up to 64 guests divided into 8 apartments (single rooms and private bathrooms). The village includes buildings with highly recognizable features thanks to the careful selection of colors and finishes with classic, almost stereotypical, but familiar and reassuring lines that limit adequately furnished spaces. Every space is designed to stimulate cognitive functions and provide a good quality of life for residents.

Methods: The retrospective cohort study involved 60 subjects. Variables collected from June 2018 to December 2020 included demographic data, cognitive and functional statuses, comorbidities, engagement in activities through the Engagement Social Index, and psychoactive medication use.

Follow-up was performed every 6 months from admission until the Tcovid (starting covid Time) period. Outcomes included any significant changes due to isolation compared with the pre-pandemic period.

Results: The study population had a mean age of 82.5 years (76.7% female), with a predominant diagnosis of AD (65%).

Assessment at Tcovid showed rather different data than those recorded in the first 18 months with accelerated worsening of MMSE and CDR scales, increased prescription of antipsychotics (+5%), antidepressants (+11.7%, p=0.045) and benzodiazepines (+1.7%), and increased number of falls delineating the worsening of functional status accelerated by the pandemic.

Limitations of the study include observational design and small sample size.

Conclusion: The pandemic resulted in an abrupt reorganization of the care model with an orientation predominantly toward the health needs by disrupting the use of shared spaces and any opportunity for cognitive stimulation. This showed how psychosocial activity and appropriate study of the built environment play an important role in the well-being of people with cognitive impairment.

Socioeconomic differences in brain white matter microstructure and associated cognitive performance in middle to older adulthood

Stephanie Schrepff¹, Olga Trofimova², Morgane Künzi³, Cristina Ramponi⁴, Antoine Lutti², Ferath Kherif⁴, Adeliya Latypova⁴, Peter Vollenweider⁴, Pedro Marques-Vidal⁴, Martin Preisig⁴, Matthias Kliegel³, Silvia Stringhini⁵, Bogdan Draganski¹

¹Geneva University Hospitals Switzerland, ²Lausanne University Hospital and University of Lausanne, ³University of Lausanne and University of Geneva Switzerland, ⁴Lausanne University Hospital and University of Lausanne Switzerland, ⁵Geneva University Hospitals, University of Geneva, and University of Lausanne Switzerland

Background and Objective: Previous research examining socioeconomic differences in brain white matter focused on fractional anisotropy or mean diffusivity, which are open to several biological interpretations. Further, pathways linking socioeconomic conditions, white matter, and cognitive performance have rarely been investigated. We aimed to provide a more detailed neurobiological understanding of socioeconomic differences in brain anatomy and cognitive performance.

Methods: We combined quantitative magnetic resonance imaging biomarkers indicative of tissue myelination and iron content with diffusion-weighted brain measures, cognitive performance (processing speed, cognitive flexibility, and fluid intelligence), and socioeconomic data (household income and occupational position) in a sample of community-dwelling individuals (n=751, aged 50 to 91 years). We adjusted the applied regression and structural equation models for the linear and non-linear effects of age, sex, education, cardiovascular risk factors, and depressive, anxiety, and substance use disorders.

Results: Individuals from lower income households showed signs of advanced brain white matter ageing with greater mean diffusivity (MD), lower neurite density (intra-cellular volume fraction; ICVF), lower myelination (magnetization transfer saturation; MT), and lower iron content (transverse relaxation rate; R2*). The association between household income and MD was mediated by ICVF (B=0.084 (0.029, 0.141), p=0.003) and MT (B=0.019 (0.006, 0.034) p=0.009); MD partially mediated the association between household income and cognitive performance (B=0.017 (0.001, 0.033), p=0.040). Household income moderated the association between white matter microstructure and cognitive performance, such that greater MD, lower MT, or lower ICVF was only associated with poorer cognitive performance among individuals from lower income households. Individuals from higher income households showed preserved cognitive performance in the face of greater MD, lower MT, or lower ICVF.

Conclusion: An individual's household income relates to their white matter brain anatomy and associated cognitive performance in middle to older adulthood, and buffers the adverse effects of white matter decline.

Age Differences in Incidence Rates and In-hospital Outcomes among adults with Stroke or transient ischemic attack: a 10-year time-series analysis

Jiaer Lin¹, Benjamin Yip², Chi Hung³, Eng Yeoh⁴

¹Jockey Club School of Public Health and Primary Care, Chinese University of Hong Kong, Hong Kong SAR, China Rm 503, JC School of Public Health Building, Prince of Wales, Chinese University of Hong Kong Hong Kong,

²Jockey Club School of Public Health and Primary Care, Chinese University of Hong Kong, Hong Kong SAR, China, ³Jockey Club School of Public Health and Primary Care, Chinese University of Hong Kong, Hong Kong SAR, China, ⁴Centre for Health Systems and Policy Research, Jockey Club School of Public Health and Primary Care, Chinese University of Hong Kong, Hong Kong SAR, China Centre for Health Systems and Policy Research, Jockey Club School of Public Health and Primary Care, Chinese University of Hong Kong, Hong Kong SAR, China Hong Kong

Background: An emerging trend of increasing strokes has been noted among the younger population. However, studies on the age differences in incidence and in-hospital outcomes are lacking, particularly for the Asian population.

Objective: To compare incidence and in-hospital outcomes and to evaluate their 10-year trends according to age and stroke subtype.

Method: A total of 137,927 patients with a primary diagnosis of stroke or transient ischemic attack (TIA) in Hong Kong between 2011-2020 were included. Outcomes were incidence, in-hospital deaths, length of stay (LOS), and 30-day unplanned readmission rates by age and subtype. Time-series analysis using cumulative annual percentage changes (CAPC) and statistical process control (SPC) was conducted to examine time trends.

Results: Decreasing incidence was observed in all subtypes among old adults (aged ≥ 65), who yielded the most dramatic incidence reduction in ischemic stroke (IS) and intracerebral hemorrhage (ICH) (per 100,000 person-years 2011-2020, CAPC; IS: 931 to 424, -54%; ICH: 180 to 101, -44%), compared to young (aged ≤ 44) and midlife adults (aged 45-64). TIA incidence increased in young by 19% but declined by 40% in old adults, whereas subarachnoid hemorrhage (SAH) incidence remained steady for young and midlife. In-hospital deaths (10%) and 30-day unplanned readmission rates (9.8%) were highest for old adults with any subtype, while acute LOS was longest in the young (mean [SD] days; IS: 6.1 [13.3]; ICH: 14.6 [47.4]; SAH: 21.9 [60.2]) except TIA. SPC analysis demonstrated a significant rise in in-hospital deaths for all IS. There were longer LOS and more 30-day stroke-cause unplanned readmissions for all subtypes in young adults over ten years, but outcomes did not change in old adults apart from IS and TIA.

Conclusion: Age-specific trends in incidence and in-hospital outcomes varied in stroke subtypes. The temporal increase in LOS and readmissions in young strokes highlight the need for age-targeted care improvements.

⁴De Gioia Department of Biomedical and Neuromotor Sciences, University of Bologna Department of Biomedical and Neuromotor Sciences, University of Bologna Italy, ⁵KOS Care s.r.l., Anni Azzurri, Bologna KOS Care s.r.l., Anni Azzurri, Bologna Italy, ⁶Villa Giulia s.r.l., Pianoro, Bologna Villa Giulia s.r.l., Pianoro, Bologna Italy, ⁷Unit of Hygiene and Quality of Residential Services, Bologna Local Health Authority, "Bellaria" Hospital, via Altura 3, 40139, Bologna, Italy.

Background and Objective: One of the most delicate events in an older persons life is the entrance to a residential care facility (RCF). For institutionalized individuals, maintaining autonomy and a good physical, mental and social health is crucial, and this can be achieved through a multidisciplinary approach. A growing literature shows that, in RCFs setting, exercise and multicomponent physical activity (PA) programs can have beneficial effects on these outcomes, in particular on mental health and cognitive functions. The aim of this study is to describe the diffusion of exercise programs in a sample of Italian RCFs and its impact on the health-related quality of life (HrQoL).

Methods: Eight RCFs belonging to Marche and Emilia Romagna Regions (Italy) were recruited in 2022. HrQoL was assessed using the Short-Form 12 questionnaire (SF-12).

Results: Preliminary results from 89 older adults (age: 84.33 \pm 8.36, 78.7% women) showed that 51% of participants performed at least 1 session of individual PA per week and about 70% of participants performed group PA. Considering the HrQoL score at baseline, a significant higher Mental Component Score (MCS) of SF-12 was observed in patients carrying out more PA group activity (>2 times per week) than in those who practiced less (≤ 2 per week) (MCS=48.91 \pm 9.90 vs 43.68 \pm 10.08, $p=0.03$). Considering the individual PA, we observed higher scores of MCS in patients carrying out more sessions per week rather than a single session (48.95 \pm 10.92 versus 45.66 \pm 9.21, $p=NS$). On the contrary, the Physical Component Score of SF12 remained unchanged based on PA frequency and modality.

Conclusion: Our data confirm that continuous group exercise is associated with higher mental wellness among elderly. These results also underline the

importance of PA-based-interventions in this specific setting in order to improve the HrQoL of this vulnerable population.

DOI: 10.18332/popmed/164075

COVID-19 vaccination among older adults in India: a case of underrepresentation

Aravinda Guntupalli¹, Aravinda Guntupalli¹, Peter Lloyd-Sherlock²

¹University of Aberdeen United Kingdom, ²University of East Anglia

Background: Older adults are known to experience higher mortality and hospitalisation when infected with COVID-19 due to their increased vulnerability. COVID-19 severely impacted Indian older adults during the first two waves of the pandemic. While India's vaccine coverage is impressive in absolute numbers, the coverage proportion, particularly among older adults, was questioned during the deadly COVID Delta wave. Hence, the analysis seeks to study the policies concerning prioritisation, and vaccine coverage among older adults in India.

Methods: Mapping of the COVID-19 policies with the COVID vaccine and mortality data published by the Government of India between December 2019 and December 2022 was carried out to explore the reasons behind the underrepresentation.

Results: Nearly 2000 million doses of COVID-19 vaccines were provided to Indian citizens as of mid-December 2022. 92% of older adults aged 60 and above received the first dose of the COVID-19 vaccine. While 88% of older adults received the second dose, only 33% received the booster dose, known as the precaution dose. While the coverage until mid-December 2022 is impressive for the first and second doses, it was not remarkable in 2021. When the COVID pandemic mortality was at its peak until July 2021, only 50% and 19% of older adults received the first and second doses. This was because older people did not receive sufficient prioritisation during the pandemic.

Conclusion: COVID-19 vaccination coverage among older adults looks promising based on recent data. However, due to a lack of prioritisation, the coverage was poorer among this vulnerable group during the peak stages of the pandemic. Future pandemic vaccination programmes must consider prioritisation of older adults to reduce overall as well as older adult specific mortality and hospitalisation in India.

Socioeconomic predictors over the life course of healthy ageing index in older Eastern Europeans

Martin Bobak¹, Maleeka Zaidi², Hynek Pikhart¹

¹Recetox, Masaryk University Czech Republic, ²University College London

Background and Objectives: Eastern Europe is facing population ageing in addition to health and socioeconomic inequalities that have emerged during post-communist transition. While it is important to consider a life course approach to the socioeconomic predictors of healthy ageing, there have been very few studies exploring this association between socioeconomic position (SEP) across the life course and healthy ageing in the Eastern European context. The aim of this study was to investigate the associations between socioeconomic predictors at different stages of the life course and a composite index of healthy ageing in Eastern European ageing cohorts.

Methods: We used data from the prospective cohort study, HAPIEE, comprising of 24,071 individuals from random population samples from urban centres in the Czech Republic, Poland and Lithuania, aged 45-75 years at baseline in 2002-2005 in the Czech Republic and Poland and 2006-2008 in Lithuania. Self-reported SEP indicators used for analysis are childhood amenities (Childhood), education (Early Adulthood), current household amenities, residents per room per room, and deprivation scale (Late Adulthood). Logistic regression was used to investigate the association between SEP across the life course and a recently developed composite Healthy Ageing Index (HAI).

Results: Education showed the most pronounced association with HAI, followed by childhood amenities, current deprivation, current amenities and crowding, with some variations between countries. The odds ratios of low HAI in those with the highest vs. lowest quintile of lifecourse accumulation of low SEP was 4.3 (95% confidence interval 3.8-4.9). Odds ratios were higher in females, in participants with older age, without partner, with lower alcohol consumption, and those reporting poor self-rated health.

Conclusion: These results have highlighted the significance of SEP at different stages of life in determining healthy ageing. Policy makers must tackle their ageing populations through addressing inequalities across the life course, in particular educational attainment.

The role of folate metabolism enzymes snps in non-obstructive azoospermia: A systematic review and meta-analysis

Flavia Beccia¹, Emanuele La Gatta¹, Drieda Zaçe¹, Ilda Hoxhaj¹, Arianna Panfil², Luigi Petrella¹, Maria Di Pietro¹, Maurizio Genuardi³

¹Università Cattolica del Sacro Cuore Section of Hygiene, Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy, ²Università Cattolica del Sacro Cuore Section of Genomic Medicine, Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy, ³Università Cattolica del Sacro Cuore Section of Genomic Medicine, Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy

Infertility represents a reproductive public and health issue. Males account for 50% of infertility cases, often considered idiopathic. Single-nucleotide polymorphisms (SNPs) have been investigated in relation to non-obstructive azoospermia (NOA), especially the folate enzymes molecular pathway. This systematic review and meta-analysis aims to evaluate the relationship between SNPs and NOA susceptibility.

PubMed, Scopus, and Web of Science were searched for studies published in English up to October 2022. Case-control studies focusing on SNPs in folate metabolism enzymes were assessed for eligibility. The Q-Genie tool was used to assess the quality of the included studies' quality. SNPs examined in more than two studies for the same genotype underwent random-effect meta-analyses, yielding pooled odds ratios (ORs) and 95% confidence intervals (CIs). I² statistic was utilized to evaluate heterogeneity.

Out of 697 search outputs, 13 articles were included, all of good quality, conducted in Caucasian (61.5%) and Asian (38.5%) ethnicity. Eight SNPs were identified and meta-analysis was conducted on four of them. The pooled ORs of SNPs and NOA were: for rs1801133 1.33 (95% CI: 1.02-1.74, I² 64.7%) for CT genotype, and 2.03 (95% CI: 1.25-3.28, I² 75.1%) for TT genotype; for rs1801131 0.99 (95% CI: 0.78-1.25, I² 23.5%) for AC genotype, and 1.01 (95% CI: 0.65-1.57, I² 0%) for CC genotype; for rs1801394 was 1.15 (95% CI: 0.79-1.68, I² 0%) for AG genotype, and 1.12 (95% CI: 0.61-2.05, I² 0%) for AA genotype; for rs1805087 1.47 (95% CI: 1.05-2.05, I² 0%) for AG genotype, and 4.28 (95% CI: 2.17-8.44, I² 0%) for GG genotype. We report a significant association between rs1801133 and rs1805087 SNPs and NOA. However, to determine the use of these SNPs for genetic testing in clinical and public health practice, more research is required. Identifying populations at higher risk of infertility could guide personalised preventive and diagnostic programs.

Prevalence and factors associated with elder abuse in an eastern state of India

Swayam Parida¹, Pradnya Chandanshive², Sonu Subba³, Shree Mishra³

¹AIIMS Bhubaneswar Dept of Community Medicine & Family Medicine Sijua India, ²Topiwala National Medical College & B.Y.L Nair Charitable Hospital, ³AIIMS Bhubaneswar Associate Professor Sijua India

Introduction: The problem of elder abuse exists in the present society and is considered an important social issue. It usually goes underreported because of the inability of the elderly to seek help and the lack of awareness regarding legal procedures. The consequences of elder abuse are enormous ranging from mental health issues to physical injury and death. Most of the available evidence has found that family members and caregivers are the ones primarily involved in the abuse of the elderly.

Objective: To find the prevalence, pattern, and associated factors of elder abuse in an urban area

Material and Method: Cross-sectional community-based study conducted between August 2019 to August 2020 in an urban field practice area of the All India Institute of Medical Sciences, Bhubaneswar. A total of 360 participants aged 60 years and above were interviewed using various semi-structured interview schedules and validated study tools such as Geriatric Depression Scale (GDS). The data obtained were analyzed using Statistical Package for the Social Sciences (SPSS) software Version 22.0.

Results: Approximately one in five (19.4%) elderly reported some form of abuse. The types of elder abuse reported were physical abuse in 12 (3.3%), verbal abuse in 25 (6.9%), emotional abuse in 40 (11.1%), and financial abuse in 15 (4.2%) elderly participants. The sons and daughters-in-law of the elderly participants were the main perpetrators of the abuse reported. Depression and past history of abuse were found significantly associated with any type of abuse.

Conclusion: The prevalence of elder abuse found in this study was considerably high, with 70 (19.4%) out of the 360 elderly participants reporting some form of abuse. Emotional abuse was the most reported, and physical abuse was the least

reported type of abuse. The most common perpetrators were those on whom the elderly depended, like their sons and daughters-in-law.

A pilot study on evaluating relationship between steps and motion in a smart home environment

Plinio Morita¹, Kang Wang¹, Shi Cao¹, Plinio Morita¹

¹University of Waterloo Canada

Background: People worldwide are living longer but have difficulty in getting sufficient healthcare treatment from hospitals. Smart home technology has been proposed as the answer to monitoring, treating and managing chronic health conditions at home. Compared with wearable technology, using smart home devices can effectively reduce individuals' burden in their daily routines and avoid any unfunctional monitoring if older people forget to wear them. The purpose of this study is to evaluate the correlation between steps data from wearable devices and motion data from smart home devices, validating the hypothesis that smart motion sensors can be used to quantify and track individuals' steps count.

Method: The study is conducted based on our smart home data ecosystem. Fourteen participants (9 male, 5 female) who are aged between 18 and 34 years old, were recruited in the study. During the experiment, participants were asked to perform basic daily living activities under researchers' instructions. Fitbit can measure participants' steps during the session, while Swidget devices can record motion data through passive infrared sensors at the same time. One whole session for a participant can last [1] three hours while the data time interval is 1 minute. As the data is not normally distributed, the Spearman correlation test was chosen as the test tool for evaluating the association.

Results: The Spearman correlation coefficient is $r = 0.42$ (range 0.35-0.67; $n=14$; PLinks:-----[1] <http://events.decortecorp.ca/!image.png>)(<https://pic.leetcode.cn/1671116442-KRbXnX-image.png>)

Barriers and facilitators for the successful implementation of antimicrobial stewardship interventions in long-term care facilities: a scoping review

Eleonora Cugudda¹, Costanza Vicentini¹, Giulia Libero¹, Carla Zotti¹, Fabrizio Bert¹

¹University of Turin Department of Sciences of Public Health and Pediatrics Italy

Background and objective: The spread of antimicrobial resistance in long-term care facilities (LTCFs) represents an important challenge. The objectives were to identify barriers arisen with implementation of antimicrobial stewardship (AMS) programs in LTCFs and to describe novel strategies to overcome them, aiming to provide guidance for effective implementation of AMS programs in LTCFs.

Methods: A scoping review was conducted through Ovid-MEDLINE, CINAHL, Embase, Cochrane Central on studies published up to 22 July 2021, considering eligible both quantitative and qualitative studies on adults residents of LTCFs experiencing an AMS program. Outcomes assessed were barriers and facilitators for implementation of interventions, then synthesized using a macro-meso-micro framework.

Results: Of 2921 papers, 71 studies met inclusion criteria. The main identified macro-level themes were policy, research, and public engagement. The most frequently cited macro-level barrier was lack of policies, protocols, guidelines and recommendations concerning AMS in LTCFs. The main identified meso-level themes were resources, program characteristics, surveillance; lack of funding and resources for AMS programs was the most cited barrier. The main identified micro-level themes were resources, surveillance, organization of work, clinician factors, patient characteristics, and patient-clinician relationship. Again, the most common theme was lack of resources. The most frequently cited macro-level strategy was developing policies, protocols, guidelines, and recommendations for AMS in LTCFs. Meso-level strategies were including regular auditing and providing feedback to prescribers in AMS programs, tailoring strategies to the local context, addressing site-specific potential implementation barriers, and fostering interprofessional engagement with participatory strategies. Strategies at micro-level were cited by the greatest number of studies; the most commonly cited theme was the organization of work.

Conclusions: By categorizing barriers and strategies according to the macro-meso-micro framework, this study could be useful to guide improvements in policy, programs and action, improving healthcare quality and patient safety in LTCFs.

Realist evaluation of the impact, viability and transferability of an alcohol harm reduction support program based on mental health recovery: the vitae study: First results

Judith Martin-Fernandez¹, Sarah Perrin², Nolwenn Stevens², Sarah Moriceau³, Fuschia Serre⁴, Marc Auriacombe¹, Sanpsy France¹, Linda Cambon²

¹Université de Bordeaux Université de Bordeaux France, ²Université de Bordeaux, France, ³Sanpsy, ⁴Sanpsy France

Methods and Analysis

The Vitae study adheres to the theory-driven evaluation framework where the realist evaluation method and contribution analysis are used to explore the effects, mechanisms, and influence of context on the outcomes and to develop and adjust an intervention theory. This study is a 12-month, multi-case, longitudinal descriptive pilot study using mixed methods. It is multi-centered, and carried out in 10 addiction centers. The target number of participants was 100 beneficiaries and 23 professionals.

Results: Among the 29 beneficiaries included in 7 addiction treatment or prevention centers in France, 66% were male (n=19) and the average age was 43 years (SD=10,3). A large majority (96%) had alcohol use disorders according to the DSM-5 criteria. At 12 months follow-up, 10 persons (34%) were retained in the IACA! Program. The unique qualitative materials will be used to describe and analyze the viability of such an intervention.

Conclusion: Viability and transferability of complex health interventions is a major public health topic and remains a highly valuable research field. This study, focusing on an innovative intervention for people with alcohol use disorder implemented in different contexts will provide valuable information for the implementation science but also for the HR field.

Popul. Med. 2023;5(Supplement):A47

Association between household air pollution and cognitive health among older adults in India: A multiple mediation approach through depression and insomnia

Subhojit Shaw¹, Sampurna Kundu²

¹International Institute for Population Sciences Govandi Station Road, Mumbai 400088 India, ²Jawaharlal Nehru University JNU Campus, New Mehrauli Road, New Delhi, India

Objectives: The relationship between household air pollution exposure and cognitive outcomes of depression cause sleep disorders, suggests that these could play a multiple mediating role in the association between air pollution and cognitive impairment, and the study aims to speculate on this mediation effect.

Method: The study utilizes data from Longitudinal Aging Study in India (LASI), 2017–2018. We have used a multiple mediating model to understand the relationship between indoor air pollution, cognition mediated through depression and insomnia, while controlling all possible confounders.

Result: Household air pollution was negatively associated with cognitive health ($\beta = -0.38$) in all models, with depression ($\beta = 0.18$) and insomnia ($\beta = 0.038$) acting as mediators. The results show that unsafe cooking practices, indoor smoke from incense sticks, mosquito coils, and secondhand smoking are associated with lower sleep quality and depression among older adults.

Conclusion: The findings suggest that household air pollution is associated with cognitive decline, but this relationship is mediated by a person experiencing depression and/or insomnia. The study lays a foundation for future investigations into this nexus to inform and formulate policies to reduce exposure to air pollutants and improve screening and access to mental health services as a public health priority.

DOI: 10.18332/popmed/164655

Older adults' risk profiles for intense care transition patterns: 15-year results from a swedish population-based study

Susanna Gentili¹, Amaia Larrañaga¹, Debora Rizzuto¹, Davide Vetrano¹

¹Karolinska Institutet Aging Research Center, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet and Stockholm University, Stockholm, Sweden.

Background: Older adults are at higher risk of experiencing frequent healthcare transitions. We aimed to quantify and characterize the care transition patterns of older adults associated to individuals' sociodemographic, clinical and functional characteristics.

Method: Data are from the Swedish National Study on Aging and Care in Kungsholmen and the Swedish Patient Register through which we assessed care

transitions between home, home care, nursing home and hospital in 3,363 older adults ≥ 60 years old. Markov multistate models were used to represent the study participants likelihood of moving across various care settings.

Results: Over 15 years, the study participants spent on average after each transition two years at home, one year at home with home care, one year in a nursing home, eight days in hospital and 17 days in post-acute care. On average, study participants experienced ten hospitalizations over the study period. Being unpartnered was associated to a significant higher hazard of transitioning from home to hospital (HR 1.12) and to be discharged from hospital to home with home care (HR 1.18) or to a nursing home (***). Similarly, multimorbidity (2+ diseases) was associated with a higher hazard to transitioning from home to hospital (HR 1.56) and to be discharged at home with home care (HR 2.40). Cognitive impairment significantly increased the hazard to be institutionalized independently from the starting setting (HR range 2.14-3.48). Slow walking speed finally increased the hazard to be hospitalized (HR range 1.14-1.28) and to be discharged at home with home care services (HR 1.20).

Conclusion: Different sociodemographic, clinical and functional characteristics trigger specific care transition patterns of older adults. Preventive strategies addressing individuals with such characteristics should be tested in the attempt to reduce healthcare fragmentation.

Popul. Med. 2023;5(Supplement):A49

DOI: 10.18332/popmed/164684

Impact of COVID-19 on football players' injuries

Vittorio Falcone¹, Giovanni Guarducci², Gabriele Messina¹, Nicola Nante¹

¹University of Siena Post Graduate School of Public Health, University of Siena, Italy, ²University of Siena

Background and Objective: Even in football and in sports, as in every aspect of social life, the balance between preserving health and the economy is the central theme. The public health impact of COVID-19 has resulted in the closure of stadiums for an extended period. The study aims to evaluate the effect of post COVID-19 on Serie A football players.

Methods: Considering two Serie A seasons, namely from 2019-20 to 2020-21, all the players who had played at least one match in both seasons were selected. Players were further divided according to the number of injuries over the two seasons. The information about injuries was obtained from the German website Transfermarkt. We verified whether there was a significant difference in injuries, through Mann-Whitney U Test, by comparing players who had COVID-19, in any of the 19-20 or 20-21 seasons, with those who did not get sick.

Results: In the 264 players analysed were not counted as injuries non-purely orthopaedic surgery, intestinal problems, infections and COVID-19. During season 19-20, only 9 players had COVID-19, while in season 20-21, 93 out of 264. Each player who has had COVID-19 lost an average of 18.6 days. For both periods, the players who had COVID-19 had significantly fewer injuries than those who had not ($p < 0.05$).

Conclusion: The analysis focused on post Covid-19 effects on Serie A players, particularly their injury numbers. Physical injuries decreased in players who had encountered the virus. This is probably because every player who had COVID-19 has been away from the football field. This might suggest that professional athletes should have no health problems if they have defeated COVID-19. However, despite the decrease in pandemic restrictions, there are still many doubts about post COVID-19, we cannot lower our guard.

Did covid-19 pandemic modify palliative care utilisation in 2020? a retrospective observational study comparing 2020 and 2019 administrative data in tuscany, Italy

Mario Bruschi¹, Francesca Collini¹, Francesca Ierardi², Silvia Forni², Alfredo Zuppiroli², Guglielmo Bonaccorsi¹, Fabrizio Gemmi¹

¹Department of Health Science, University of Florence, 50134 Florence, Italy, ²Quality and Equity Unit, Regional Health Agency of Tuscany, 50141 Florence, Italy.

Background and objective: The COVID-19 pandemic has highlighted the need for palliative care (PC) to relieve suffering at the End-of-life (EOL). The study aims to assess the early impact of COVID-19 over EOL quality of care received by patients, comparing 2019-2020 data.

Background & objective: The COVID-19 pandemic has highlighted the need for palliative care (PC) to relieve suffering at the End-of-life (EOL).

The study aims to assess the early impact of COVID-19 over EOL quality of care received by patients, comparing 2019-2020 data.

Methods: Retrospective observational study based on administrative data. The

study population includes all Tuscany region (Italy) residents (≥ 18 years) died from 01/01/2019 to 31/12/2020 with a clinical history of cancer and/or with chronic diseases (heart-failure/chronic-pulmonary-disease/dementia/ictus/amyotrophic-lateral-sclerosis/muscular-dystrophy/myotonic-dystrophy/kidney-failure). Patients were divided upon year of death. EOL care quality outcome measures were evaluated. Analysis was performed using STATA-15 (significance $P < 0.001$). Results: 31.758 patients died in 2019, 33.967 in 2020.

Both years patients-selection represented over 70% of Tuscany decedents; 52% of patients being females and more than 70% being over 75 years old.

In last 30 days of life, 2020 group (vs 2019) showed significantly:

lower hospital burden: Emergency Department (ED) admission (52.1% vs 56.2%), ED admission (non-hospitalized) (37.9% vs 41.4%), hospitalization (56.0% vs 62.8%), hospital as the place of death (30.5% vs 34.0%), chemotherapy (3.9% vs 5.5%) but higher use of new chemotherapy (3.0% vs 1.9);

higher ICU burden (not significant): ICU admission (69.8% vs 48.4%), use of life-sustaining treatments (22.0% vs 18.4%);

lower utilization of PC services: hospice services (5.7% vs 7.7%; 3.6% vs 5.0% if considering last 7d), opioid therapy (24.7% vs 25.9%), active home PC services (21.0% vs 22.6%), no PC support (70.3% vs 68.8%).

Conclusion: The pandemic, due to fear of the disease, contributed to reducing hospital burden for patient with EOL needs but failed to strength PC response, thus lowering EOL quality of care and contributing to inequalities.

Further studies are needed to evaluate the mid-long term impact of COVID-19 pandemic on quality of EOL care, especially after the introduction of vaccines since 2021.

Community-based program focused on social support limits covid-19 mortality: a retrospective cohort study

Giuseppe Liotta¹, Leonardo Palombi¹, Olga Madaro², Clara Donnoli¹, Giulia Picardo¹, Maria Marazzi³, Fabio Riccardi¹, Leonardo Gialloreti¹

¹Biomedicine and Prevention Department, University of Rome Tor Vergata Italy, ²"Long Live the elderly!" program, Community of Sant'Egidio, Rome, Italy, ³LUMSA, University of Rome Italy

Background: COVID -19 pandemic mortality hit especially people over 80 years. This paper aims to assess the impact of Community-based pro-Active Monitoring Program (CAMP) on octogenarians' survival, during the COVID-19 pandemic.

Methods: The CAMP "Long Live the Elderly!" supports to the over 80s population living in selected Urban Area (UAs) of Rome. The paper compares mortality in these UAs with the mortality of adjacent neighbourhoods, which were not served by the CAMP program, between October 2020 and March 2021. Mortality was stratified by COVID-19 incidence, percentage of people living alone, and income per capita by means of a Generalized Linear Model weighted for the UAs' > 80s population. The Rome Municipality Statistics Office provided data on mortality.

Results: Between October 2020 and March 2021 the Statistics Office reported 234 (56.5/1000) deaths in the zones served by CAMP and 477 (52.9/1000) deaths for the UZs not served by CAMP. The increase in mortality compared to the same period of the previous year was 37 (22.4%) and 74 (25.2%) respectively for UAs served and not served by CAMP. The absence of CAMP, weighted for the population and adjusted for the COVID-19 incidence, and the percentage of Older Adults >80 living alone, was associated to a 37% increase of deaths ($p < 0.001$).

Conclusions: Mortality among octagenarians increased during Rome's worst phase of COVID-19 pandemic. The implementation of CAMP is associated with a containment of mortality. Social support might be one of the reasons for this result. However, given the limited sample size, further research is warranted.

DOI: 10.18332/popmed/164321

Trends in the geriatric workforce in the romanian healthcare system

Monica Brînzac¹, Maria-Lorena Vescan², Monica Brînzac^{1,3}, Marius Ungureanu¹

¹Department of Public Health, Faculty of Political, Administrative and Communication Sciences, Babeş-Bolyai University; ²Center for Health Workforce Research and Policy, Faculty of Political, Administrative and Communication Sciences, Babeş-Bolyai University "1 Cluj-Napoca, Romania ²Cluj-Napoca, Romania, ³Department of Public Health, Faculty of Political, Administrative and Communication Sciences, Babeş-Bolyai University Cluj-Napoca, Romania Romania, ³Center for Health Workforce Research and Policy, Faculty of Political, Administrative and Communication Sciences, Babeş-Bolyai University

Background & objective

The importance of the geriatric health workforce is pivotal in relation to the aging populations, their constantly expanding needs, and the increasing frailty. Specifically, people over 65 years old are accountable for 18.9% of the romanian population, which is close to the eu level of 20.6%. Additionally, the romanian healthcare system encounters challenges regarding the healthcare workforce, such as human resources migration, the lack of a comprehensive health workforce policy, and assuring adequate numbers and distribution. This paper aims to assess the trends in the geriatric workforce between 2016-2022 in romanian, with a particular focus on the differences between regions.

Methods: The study has a quantitative, longitudinal design implying secondary data analysis conducted on doctors specialized in geriatrics. We used the annual report on the activity of healthcare facilities and the national statistical yearbook issued by the national institute of statistics for 2016-2022 population-related data.

Results: At the national level, the number of geriatricians increased by approximately 43%, from 210 in 2016 to 300 in 2022. The results indicate an aging workforce, as the highest share was represented by doctors aged 53, respectively 54 years old. In terms of distribution, the south region holds the highest number of geriatricians, with a 44.8% difference from 2016 (n=125) to 2022 (n=181). alternatively, the west region had the lowest numbers, with a 16.67% increase (n=6 geriatricians in 2016 compared to n=7 geriatricians in 2022). In this region, the ratio of inhabitants aged over 65 years old reported to geriatricians has decreased from 52,98 in 2016 to 51,14 in 2022.

Conclusions: The romanian healthcare system has tremendous differences concerning geriatricians' distribution between counties. Despite the slight increase over the years, the number of geriatricians reported to the aging population should represent an interest for the policymakers.

A comparative analysis on the approaches of patients about stem cell treatments in turkey

Ciler Dursun¹

¹Faculty of Communication, Ankara University, Cebeci, Turkey

Regenerative and restorative innovations in medicine is one of the contested area for the patients and their relatives in terms of both by offering new treatments and also by carrying some ambiguities through their implementation process. Among these innovations, stem cell treatments are on the front line that patients approach towards it with the curiosity, hope and expectations. In order to measure approaches of patients with diverse demographical features in Turkey, we're conducting nationwide Project entitled as "The Socio Cultural, Economic, Ethical and Law Effects of Regenerative and Restorative Medical Technologies in Turkey" since 2021 with the support of The Scientific Research and Technological Research Council of Turkey. This projects is aiming at a comparative analysis on the differences and similarities of the approaches between the patients with high socio-economical status and the patients with relatively low socio-economical status. In order to obtain diverse approaches, a vast survey is implemented to the patients in Ankara, İstanbul, İzmir and Erzurum which are the four main metropol cities that represents socio- cultural diversity in Turkey. Survey is answered by the 750 patients both in the University hospitals and private hospitals. Ankara University, Ege University and Istanbul University hospitals are representing public hospitals by offering costless health care services in the sample, while two private hospitals are representing paid health care services in Turkey. Preliminary remarks of the survey are displaying that although there are some differences between patients about their general attitudes towards health issues in their life, the approaches of the patients are more similar in terms of supporting innovative medical Technologies and treatments according to their socio-economic status. This Project is also giving some clues on the expectations of the patients with diverse socio-economical and cultural status from the governments about bearing the costs of stem cell treatments in Turkey.

Self-rated health status in south africa: the roles of neighborhood disadvantages, social trust and religion

Raege Omar¹, Thankam Sunil², Xiaohe Xu¹

¹University of Texas at San Antonio United States, ²University of Tennessee, Knoxville United States

Background and objective: Self-ratings about personal health are broad self-evaluations of health status which reflect general dimensions of health including chronic conditions. The construct of Self-rated health is related to multiple

domains of health outcomes such as mortality rates, comorbidities, psychological distress and the numerous psychosocial effects that result from socio-economic inequalities in health. The primary focus of our study is to apply a theoretical framework drawing on the stress process paradigm to examine the central research question: Do religiosity dimensions and social trust mediate and/or moderate against the deleterious effects of one ecological chronic stressor: neighborhood disadvantages?

Methods: This study applies nested models using stereotype logistic regression to analyze a random probability sample ($n=3531$) from the World Values Survey (WVS) in South Africa. Self-rated health was measured in a single survey question: All in all, how would you describe your state of health these days? In response, study participants were asked to indicate where they would put themselves on an ordinal scale (i.e., Very Good; Good; Fair; Poor).

Results: (1) Neighborhood disadvantages predicted lower self-ratings of health ($p < 0.00$), controlling for respondents' demographic characteristics, income, employment, religious affiliation and exposure to violence in the past year; (2) the effects of social trust were only limited to mediate against ecological stress; however (3) higher religious engagement predicted more favorable ratings on health status, thus diminishing the negative effects of the stressor.

Conclusion: This study contributes to the literature by investigating the interface between self-rated health and ecological chronic stress in sub-Saharan Africa. Our empirical results lend credence to the positive effects of social involvement to mitigate the deleterious effects of neighborhood disadvantages.

LISA - Health Literacy cohort study

Sara Dias¹, Maria Batalha¹, Rui Passadouro², Estêvão dos Santos³, Bartolomeu Alves², Tiago Gabriel², Ana Valentim⁴, Cátia Gomes⁴

¹Center for Innovative Care and Health Technology, Polytechnic of Leiria
Center for Innovative Care and Health Technology, Polytechnic of Leiria
Rua General Norton de Matos, Apartado 4133 Portugal, ²Unidade de Saúde Pública do ACES Pinhal Litoral Unidade de Saúde Pública do ACES Pinhal Litoral e Politécnico de Leiria, PT Portugal, ³Unidade de Saúde Pública do ACES Pinhal Litoral, ⁴Câmara Municipal de Leiria

Background and objective: Health literacy (HL) is the degree to which individuals can find, understand, and use information and services to inform health-related decisions and actions for themselves and others, whether at home, at the workplace, in the community, marketplace, healthcare sector, or the political arena. LISA is a cohort study developed in Portugal, which aims to measure HL in the adult population of Leiria, over the next 10 years. As secondary objectives it is intended to characterize anxiety and depression and metabolic risk.

Methods: LISA is a population-based prospective cohort study. It will collect data on HL through European Health Literacy Survey (HLS19-Q12). The study population will be composed by adults (≥ 18 years old) who are non-institutionalized and living in private households in Leiria. The random sample is stratified by gender and age groups. A face-to-face interview will be conducted with the Computer Assisted Personal Interview at baseline. Follow-up will be carried out every 2 years via telephone call. The association between independent variables and health literacy is examined by means of variance analysis with measurement repetition.

Results: The measuring instruments will allow a diagnosis of the situation in the municipality of Leiria. It will be possible to develop specific strategies and initiatives to promote HL, that will allow each citizen to make an informed decision, and that contribute to better health outcomes, more efficient use of health services, and decrease in health spending.

Conclusion: The HLS-EU revealed that 47.6% of respondents in Europe had limited HL. Given these issues, it is necessary to train and inform about the disease and what everyone should do to fight it and, above all, prevent it. This is the HL process that should empower citizens with knowledge to make conscious and informed decisions about the promotion of individual and collective health.

Ethical issues in long-term care in low-, middle- and high- income countries during the covid-19 pandemic

Preet Gandhi¹, Theresa Nitti², Angel Petropoulos², Andreea Popescu², Nipa Chauhan², Darren Bugaresti², Paula Chidwick², Jill Oliver²

¹University of British Columbia Canada, ²William Osler Health System, Canada

Background: Long-term care (LTC) centres experienced an unprecedented emergency involving exponential mortality during the COVID-19 pandemic, placing residents, staff, families and organizations in a precarious position. Complex

issues surrounding how to best support elderly populations at great risk in the pandemic have highlighted the importance of gathering information on ethical issues to inform effective policy and decision-making. While several national and international reports have documented the multifactorial impact of COVID-19 on LTC residents' living conditions, to our knowledge, no literature currently offers stakeholder-identified ethical issues from across low, middle, and high income countries (LMIC; HIC) and different sociocultural contexts during the pandemic.

Objective: In collaboration with the World Health Organization Public Health Emergency Preparedness and Response Ethics Network, this project sought to identify ethical issues faced in LTC by residents, families, staff and organizations. The aim of this survey was to better understand the ethical issues being faced in LTC and inform public health policymaking in future health crises.

Methods: Using snowball recruitment and a participatory approach, a survey was distributed in 8 languages including: English, Spanish, French, Hindi, Portuguese, Arabic, Mandarin, and Russian.

Results: 305 respondents from 45 countries highlighted the dozens of ethical issues in LTC care during the COVID-19 pandemic. A content analysis found overlap in the themes of responses between stakeholders. Visitation, isolation, harm, staff well-being, and the overall enforcement of policies during the pandemic represented the most often discussed issues. We found overlap in the identification of many ethical issues faced by stakeholders across LMIC and HIC countries.

Conclusion: Attention to the nature and impact of this ethical issues is required for an effective pandemic response, towards addressing moral distress for all stakeholders. Future investigation is necessary to further understand how these ethical issues can be addressed and subsequently guide future pandemic policymaking.

¹University of Cambridge United Kingdom, ²Kings College London, ³Kings College London United Kingdom

Background: Infections in older people are a major cause of mortality and morbidity and may be important modifiers of outcomes for people with dementia. We explored mortality in individuals with dementia admitted to hospital for infections alongside deprivation.

Methods: A retrospective cohort analysis was created using secondary care data from one of Europe's largest mental health and dementia care providers in South London (UK). People with recorded dementia between January 2008 and March 2017 were linked to national hospitalisation and mortality data and classified as either admitted for infections, admitted for other causes or no admissions around first recorded dementia diagnosis and followed to death or a census date on 31st March 2019. Multivariate Cox proportional hazards regression with date of first dementia diagnosis as index date were applied.

Results: In total 14,375 people diagnosed with dementia were included, of whom 3,480 (24%) were admitted for infections, 3604 (25%) admitted for other causes and 7,291 (51%) not admitted to hospital. Individuals with dementia admitted for infections had lower MMSE scores, higher rates of co-morbidity and ranked significantly higher on deprivation indices compared to those with no admissions. Adjusted multivariate Cox regression models indicated that people with dementia admitted to hospital for infections had significantly higher mortality rates compared to no admissions (Hazard ratio (HR): 2.3; 95% confidence interval (CI): 2.1 - 2.5) and to admissions for other causes (HR: 1.5; 95% CI: 1.4 - 1.6).

Conclusions: In people with dementia, admissions for infections are critical events associated with substantial increased mortality risk. Addressing care patterns both before and after admission with a focus on infection could improve outcomes and is a key health research area, with optimisation of care a direct priority.

Understanding levels of morbidity, disease pattern, and hospitalization among widowed women in west bengal, India

Sandip Das¹, T.R. Dilip²

¹International institute for population sciences, ²International institute for population sciences Govandi Station Road, Deonar, Opposite Sanjona Chamber, Mumbai, Maharashtra 400088 India

Background and objective: The health condition among Widowed Women is a serious concern in West Bengal, India. The purpose of the study is to investigate

the levels of self-reported morbidity, disease pattern, and hospitalization among widowed women in West Bengal, India based on the National sample survey data. Methods: Using data from the 75th round of the National Sample Survey Organization (NSSO), we tried to analyze the levels of morbidity, disease pattern, and hospitalization of widowed women across the state of West Bengal in India. Bivariate analysis and Logistic regression analysis were carried out to assess the differentials in reported morbidity, disease pattern, and hospitalization among the widowed women.

Results: Our result shows that there is 64.7% of widowed women lived in Rural and 35.3% lived in Urban areas. Widowed women from urban areas are more like to be reported (OR:1.53, $p<0.05$) than rural areas. The burden of illness and hospitalization among widowed women was higher in rural areas than in urban areas in West Bengal. The pattern of different morbidity suggests that West Bengal is passing through the advanced phase of epidemiological transition in which non-communicable diseases increase and communicable diseases are being swiftly replaced.

Conclusion: Our study strongly suggests that widowed women especially older widowed Women have more Proportion heading of self-reported morbidity and Hospitalization in West Bengal. Policy interventions should focus on the health of widowed women in the near future.

COVID-19 pandemic impact on ncds prevalence among the elderly in Italy

Virginia Casigliani¹, Benedetta Contoli², Valentina Possenti³

¹University of Pisa Department of Translational Research and New Technologies in Medicine and Surgery via Paolo Savi 10, Pisa Italy, ²Istituto Superiore di Sanità Valentina Minardi Istituto Superiore di Sanità Italy,

³Istituto Superiore di Sanità Italy Maria Masocco Istituto Superiore di Sanità Background and Objectives: The COVID-19 pandemic had a severe direct and indirect impact on older adults. In Italy, from 2020 to January 2022, the excess of all-cause mortality was 178.000 deaths, compared to the period 2015-2019, mainly among people aged over 80(74,6% of the excess). This study aims to assess the Non-Communicable Diseases(NCDs) prevalence among the elderly in Italy after two years of the pandemic.

Methods: We used data on the elderly population(65+) collected from 2016 to 2021 by the Italian ongoing surveillance system PASSI d'Argento to analyze socio-demographic characteristics and NCDs prevalence. We compared pre-pandemic(2016-2019) and pandemic period(2020-2021).

Results: In the pandemic period, 6 of 10 people aged over 65 referred to have been diagnosed with one or more NCDs in their lifetime: 28% cardiopathy, 20% diabetes, and 13% cancer.

A condition of polichronicity(2 or more NCDs) was reported in 1 of 4 cases. People older than 85 years old, residents in the South, having economic difficulties or a lower level of education were at higher risk of having two or more NCDs. Differences by sex were not found significant.

The temporal analysis of the NCDs prevalence did not show significant changes between 2016 and 2019, except for an upward trend in polychronicity. In 2020-2021 there was a reversal of this trend, with differences at the limit of statistical significance: people with poly-chronicity decreased from 62%(60.2-61.6) in 2019 to 59%(58.1-60.7) in 2021. Oppositely, in the age-group 18-64, the NCDs trend remained unvaried.

Conclusion: The NCDs prevalence showed a decrease compared to the pre-pandemic period. It may be explained by the excess of mortality caused by the pandemic. Having an agile system that can monitor changes in the elderly it is essential to identify their needs and implement targeted actions to improve the offer of the national healthcare system.

Violence against women in a Brazilian state capital city: a population-based study

Franciële Leite¹, Márcia Pedrosa²

¹Universidade Federal do Espírito Santo, Brazil, ²Universidade Federal do Oeste da Bahia, Brazil

Introduction: Violence against women is a public health problem for which exposure to this phenomenon has negative consequences on the victim's health, regardless of the type. Objective: To estimate the prevalence of intimate partner violence against women throughout life, and its association with life experiences. Methods: This is a cross-sectional, analytical, population-based study carried out in the city of Vitória, capital city of Espírito Santo, Brazil. The

municipality has 79 districts and six health regions. The sample consisted of 1,086 women aged 18 years or older, who had or had an intimate partner in the last 24 months prior to the interview, which took place between January and May 2022. An intimate partner was defined in this study as the partner or ex- current partner and/or boyfriend as long as they maintain sexual relations, regardless of whether it is a formal union or not. Data collection was performed by a properly trained team, all female. The research team also had supervisors. The analyzes were done in the Stata version 15.1 program. The study was approved by the Ethics and Research Committee. Results: The lifetime prevalence of intimate partner violence against women was 47.8% (95%CI 44.8-50.8). Psychological violence was the most frequent (45.2%; 95%CI 42.3-48.2), followed by physical violence (25.6%; 95%CI 23.1-28.3). Sexual violence had the lowest frequency (17.2%; 95%CI 15.1-19.6). Women with a history of mothers who suffered intimate partner violence and who were sexually victimized in childhood had a higher prevalence of psychological, physical and sexual violence committed by an intimate partner ($p<0.05$). Conclusion: Intimate partner violence is a prevalent event in a woman's life, and is associated with the experience of intergenerational and personal victimization.

Older adults' intention to use an electronic decision aid for housing decisions: an online pan-Canadian survey

Maya Fakhfakh¹

¹Laval University, Canada

Background: Older adults experiencing disabilities such as frailty and loss of autonomy face the decision of whether to stay at home or move to a healthcare facility such as skilled nursing care facilities. Thus, they may need support for this difficult decision.

Objective: We assessed Canadian older adults' intention to use an electronic decision aid (eDA) for making housing decisions and identified the factors that influenced their intention.

Methods: We conducted a cross-sectional study using an online survey targeting older adults across the 10 Canadian provinces and 3 territories. We adapted 17 Unified Theory of Acceptance and Use of Technology (UTAUT) items to measure respondents' intention to use the eDA for housing decisions, as well as items measuring intention constructs. We also assessed e-Health literacy using subjective and Objective scales. We used descriptive statistics and multivariate linear regression analyses to identify factors influencing the intention to use the eDA.

Results: Of the 1,176 who met the eligibility criteria, 1,000 respondents completed the survey. The mean age was 72.5 ± 5.59 years. Most respondents were male, white, English-speakers and living in Ontario or Quebec in urban areas. Mean scores for subjective e-Health literacy were 27.8 ± 5.88 out of 40 and for Objective e-Health literacy, 3.00 ± 0.973 out of 5. In our sample, the intention score was 4.74 ± 1.7 out of 7. In the final model, factors associated with intention included mother tongue, e-Health literacy, performance expectancy, social influence and facilitating conditions.

Conclusions: Findings from this pan-Canadian online survey suggest that Canadian older adults' intention to use an eDA to make housing decisions are similar to Findings in other studies using UTAUT. Factors identified as influencing intention will guide future strategies for implementing the eDA.

Prevention policies to protect the adult population: The project "Vivere nei Parchi" in Apulia, South of Italy

Alessia Quaranta¹, Maria Balducci², Nehludoff Albano³, Onofrio Mongelli³, Osvalda Giglio⁴, Maria Montagna⁴

¹Interdisciplinary Department of Medicine, University of Bari Aldo Moro, Italy, ²Department of Biomedical Sciences and Human Oncology, University of Bari Aldo Moro, Italy, ³Department of Health Promotion and Animal Welfare, Apulia Region, Italy, ⁴Interdisciplinary Department of Medicine, University of Bari Aldo Moro, Italy

Background and Objectives: Active Ageing is a priority theme in Public Health. In accordance with the objectives of the Regional Prevention Plan (PRP) 2021/2025 on Health Promotion, Apulia Region has approved the project "Vivere nei Parchi - Puglia.M.I.C.A." (Integrated Motor Activity Culture Environment), with the strategic Objective of counteracting sedentary lifestyle and promoting paths for autonomy and psychophysical and social well-being of the Apulian population over 55.

Methods: Regional organizations, regional Parks/Reserves management bodies,

local associations specialized in the promotion and protection of naturalistic, historical-artistic heritage as well as universities are the social actors enlisted in Apulia to implement the document of the project and plan any corrective strategies. The project provides for the next two-year period 2023-2024, the activation of functional paths combining physical activity within the regional Protected Areas with the training of citizens on issues of environmental, food and archaeological/cultural education. All social and health data deriving from the program will be analyzed and monitored in order to verify their adherence with the Objectives set.

Results: The expected Results are mainly aimed at the conscious adoption of healthy and active lifestyles by the elderly adult, but they also involve the improvement of the perception of the state of health; empowerment; the enhancement of the resources of the territory; the elimination of health inequalities and socio-cultural integration.

Conclusions: Promoting policies oriented to active aging, able to sustain virtuous changes in behavior by the population over time is one of the most difficult challenges to pursue in Public Health, but we do believe that the use of the integrated approach of intervention and the combination of physical activity-training are some of the essential elements to hope to get the expected results.

Husbands' cognitive function was associated with the spouse's depression and contact with their children

Jin-young Min¹, Kyoung-bok Min², Sang-Won Ha³

¹Veterans Medical Research Institute, Veterans Health Service Medical

Center, Seoul, Republic of Korea, ²Department of Preventive Medicine,

College of Medicine, Seoul National University, Seoul, Republic of Korea,

³Department of Neurology, Veterans Health Service Medical Center, Seoul, Republic of Korea

Background and Objective: As people age, cognitive function is an important indicator of health and mortality risk. An important factor affecting cognitive function is family members, especially spouse and children. This study investigated the cross-partner association between depressive symptoms and cognitive function. We further examined the cognitive performance of couples was affected by the frequency of contact with their adult children. **Methods:** The survey was conducted at the Veterans Medical Research Institute in the Veterans Health Service Medical Center. A total of 235 individuals volunteered for this study and provided their informed consent at enrollment. After the selection process, 96 couples participated in the present study. Participants completed a neuropsychological test battery including attention, language and related functions, visuospatial functions, memory, and frontal/executive functions. Symptoms of depression were assessed using the short version of the Geriatric Depression Scale. The number of contacts with children was categorized into ≥ 1 per month and < 1 per month.

Results: We found a significant association between depression and cognitive function between husbands and wives. Although the association was asymmetric: wives' depressive symptoms were significantly associated with lower executive function tasks by their husbands, whereas the converse association was not significant. Similarly, within a couple, more contact with adult children (more than once a month) was associated with a significantly higher cognitive scores (particularly in visuospatial/executive functions) by husbands. These observed associations were independent of the individuals' age, education, income, smoking status, alcohol consumption, engagement in moderate physical activity, and disease histories. **Conclusions:** Among older married couples, the cognitive functions of husbands tend to be influenced more by their wives' mental health and degree of contact with their adult children. This infers that wives and offspring can act as buffer against the cognitive impairment of older married men.

Association between confinement and post-COVID-19 pandemic anxiety

Melissa Fernandez¹, Vanessa Jimenez², Brian Enrique Contreras Mella², Karen Hernandez³, Lourdes Juan³, Angel Geronimo³, Christian Estudillo³, Josue Villegas-Domínguez³

¹Mexico, ²School of Medicine, Universidad del Valle de Mexico, Mexico,

³Universidad del Valle de Mexico, Mexico

background: The changes in peoples lifestyle during the COVID-19 pandemic due to the confinement assigned in different countries caused different mental health problems, so it is important to identify the consequences once this stage is over. **Objective:** To determine the association between confinement and the presence

of post-COVID-19 pandemic anxiety.

Methods: A cross-sectional, prospective study was carried out between January and April 2022, three months after return to usual activities free of confinement, including men and women aged between 18 and 50 years, residents of the city of Veracruz, excluding participants with already diagnosed psychological disorder, such as depression or anxiety. A survey was applied through Google Forms, including the Beck anxiety scale (Cronbachs alpha 0.90). SPSS v22 software was used for data analysis, Chi square test with Odds Ratio (OR) and 95% confidence interval (95%CI), assigning statistical significance with $p < 0.05$ when comparing between people with and without anxiety.

Conclusions: The presence of anxiety during the current post-pandemic stage of COVID-19, where the indication of mandatory confinement has been withdrawn, is not associated with the different behaviors carried out during the mandatory confinement stage.

Key: Anxiety is a disease that increased during the confinement stage, which, apparently, can be recovered shortly after the withdrawal of this measure. It's essential to be able to generate knowledge and be able to provide comprehensive care to the population in the event of a new epidemic.

Popul. Med. 2023;5(Supplement):A65

DOI: 10.18332/popmed/165218

Prevalence and associated factors of food insecurity among adults in Manaus

Carolina Ferreira¹, Marcus Silva², Tais Galvão³

¹School of Pharmaceutical Sciences, State University of Campinas, Brazil,

²Postgraduate Program of Pharmaceutical Sciences, University of Sorocaba,

São Paulo, Brazil, ³School of Pharmaceutical Sciences, State University of Campinas, Campinas, Brazil

Background and Objective: Food insecurity implies lack of access to food necessary for a healthy life, marked by socioeconomic vulnerabilities. We aimed to assess the prevalence and factors associated to food insecurity in Manaus, a city in the Brazilian Amazon. **Methods:** This was a population-based cross-sectional study conducted in 2019 with adults (≥ 18 years-old) selected by a probabilistic sampling in three stages. The presence of food insecurity was measured using the Brazilian Household Food Insecurity Measurement Scale adapted and validated in Brazil to measure food insecurity as mild, moderate, or severe. Descriptive statistics was conducted and the prevalence ratios (PR) with 95% confidence interval (CI) were calculated using multinomial logistic regression, adjusted by significant variables at the level of $p < 0.10$. Associations to food insecurity were considered if $p < 0.05$. Stata 14.2 and complex design were used in all analyses.

Results: Of the 2,321 participants included in this study, 38.0% (95%CI 36.0-40.1%) had mild; 14.3% (95%CI 12.8-15.8%), moderate; and 15.7% (95%CI 14.1-17.2%), severe food insecurity. Mild, moderate and severe food insecurity was more prevalent in women (mild:PR 1.35, 95%CI 1.08-1.68; moderate:PR 1.61, 95%CI 1.19-2.17; severe:PR 1.48, 95%CI 1.09-2.02), poorest individuals (mild:PR 1.56, 95%CI 1.09-2.23; moderate:PR 6.46, 95%CI 3.38-12.33; severe:PR 6.30, 95%CI 3.27-12.13), people with depressive symptoms (mild:PR 1.41, 95%CI 1.04-1.91; moderate:PR 2.59, 95% CI 1.80-3.72; severe:PR 2.50, 95%CI 1.76-3.54) and that suffered life threatening events in the previous year (mild:PR 1.75, 95%CI 1.39-2.21; moderate:PR 3.94, 95% CI 2.63-5.89; severe:PR 4.46, 95%CI 2.94-6.77). Severe food insecurity was also more frequent in people aged from 45-59 years (PR 2.49, 95%CI 1.50-4.15), and unemployed or housewife (PR 2.91, 95%CI 1.76-4.80). **Conclusions:** Food insecurity affected more women, the poorest, people with depression, and those who suffered threatening events. Social vulnerabilities and threatening events seem to add up and worsen the right to access to food.

Popul. Med. 2023;5(Supplement):A66

DOI: 10.18332/popmed/165235

Knowledge and perceptions of Alzheimer's disease among geriatric nurses, geriatric nurses' practitioners and nursing students working in varied health care settings

Anat Romem¹, Ronit Pinchas-Mizrachi², Beth Zalcman²

¹Jerusalem College of Technology (JCT), Jerusalem, Israel, ²Jerusalem College of Technology, Jerusalem, Israel

Background: The Global action plan on the public health response to dementia 2017-2025, a adopted by World Health Organization, aims to improve the lives of patients with dementia, their families and caregivers, provide comprehensive care, and implement targeted areas of action (WHO, 2017). Caring for patients with Alzheimer's disease (AD), a subset of dementia, requires specific knowledge, skills, and attitude (Kimzey et al, 2016; World Health Organization, 2020). Assessment of nursing knowledge of, and attitudes related to, caring for AD in different healthcare settings with different levels of education can help create

educational programs and change attitudes towards AD patients.

Methods: This quantitative, cross-sectional study explores self-reported knowledge related to AD and personal attitude regarding caring for AD patients. The study utilizes the following validated measures: Alzheimer's Disease Knowledge Scale (ADKS) and the Dementia Attitude Scale (DAS). The study compares between different levels of nursing education and between three healthcare settings: general hospitals, long-term care facilities, and community-based care.

Results: Overall mean ADKS score was 78.71%. The highest scores were measured in the community setting, with knowledge graded as 80.45%. The total DAS score among all study participants was 109.56/140 (78%) (SD=15.52). Nursing students' attitude toward AD patients was the lowest among all participant groups, 103.25/140 (73%) (SD=14.88). By level of education, nursing students report feeling the least comfortable with AD patients, while nurse practitioners are the most engaged and comfortable with AD patients.

Conclusions: Nursing students need increased exposure to AD patients in geriatric clinical practice as part of their nursing educational program. More knowledge and positive attitudes will facilitate better care for older adults with AD across all healthcare settings, which promotes the global action plan 2017-2025 among the nursing sector.

Women and tobacco: smokers clinical characteristics at a Tunisian tobacco cessation consultation during a 10-year-period

Aroua Kamel¹, Houyem Said², Rania Bannour¹, Sana Bhiri¹, Fatimaezzahra Khouya¹, Arwa Neffati¹, Emna Hariz¹, Souhir Ayadi¹, Soufiene Aidani¹, Mohamed Rejeb¹, Salwa Khefacha¹, Asma Cheikh¹

¹Department of Prevention and Safety of Care, Sahloul University Hospital, Sousse, Tunisia, ²Department of Prevention and Safety of Care, Sahloul University hospital, Sousse, Tunisia

Introduction: Smoking is one of the most serious threats to global public health and the most widespread in Tunisia. The incidence of female smokers is increasing through the years, as well as the incidence of hospitalizations for cardiovascular complications and cancers testifying to the high risk in this gender. **Objectives:** To describe the sociodemographic and medical characteristics of female smokers. **Methods:** A longitudinal descriptive epidemiological study was carried out among female smoking patients followed up at the smoking cessation consultation at the Sahloul University Hospital in Sousse, during the period from 2011 to 2021. The collection of socio-demographic and medical data was based on a pre-established synoptic form and validated questionnaires in Arabic and French completed during an interview with the participants.

Results: A total of 92 patients were identified. The median age was 37 years (29.25 - 50). Overall, 18.5% of patients had comorbidities, the most common being hypertension (9.9%) and diabetes (5.6%). The median age of the first cigarette use was 18.5 years (16 - 20) and 20 years (17 - 22) for daily smoking. Cross addiction was identified among 6.4% participants. Using the Fagerström score, 38.5% of women were highly dependent. Moreover 41.7% presented a high score of depression score and 25% of anxiety. Smoking cessation prevalence was 9.1% and 20% at 6 and 12 months, respectively. **Conclusions:** Smoking is steadily increasing in women. Therefore, the implementation of smoking cessation interventions targeted to women remains a necessary measure.

Factors of high physical dependence on nicotine among Tunisian smokers consulting a smoking-cessation unit in a University Hospital in Tunisia

Emna Mziou¹, Hela Ghali², Rania Bannour², Sana Bhiri², Salwa Khefacha², Mohamed Rejeb³, Asma Cheikh³, Houyem Laatiri³

¹Prevention and Healthcare Security Department, Sahloul University Hospital, Sfax, Tunisia, ²Prevention and Healthcare Security Department, Sahloul University Hospital, Sousse, Tunisia, ³Prevention and healthcare security Department, Sahloul University Hospital, Sousse, Tunisia

Smoking is an addictive behavior; nicotine is the main substance responsible for physical and moral dependence. The aim of this study was to determine characteristics of Nicotine-physical-dependence among Tunisian smokers. We conducted a descriptive study, over 5 years (2015-2020), including all patients consulting voluntarily the smoking cessation unit in Sahloul University Hospital-Tunisia. The physical dependence on nicotine was measured via the Fagerström test for Nicotine Dependence (Six questions form, summing from Zero to 10). Smokers with a score of 7 to 10 were considered highly dependent on nicotine; score from five to 6 were considered moderately dependent and from 0 to 4 were

not considered dependent. From 2015 to 2020, 450 smokers consulted our unit. When interviewing the patients, their moral dependence (addiction) to tobacco explained by themselves to gestural automatism (81.8%), stressful situations (76.7%) and the need for moral support (70.2%). As for the physical tobacco dependence, the Fagerström scale revealed that 46.2% (n=196) were highly dependent, 34% were moderately dependent and 20% were not very dependent. These highly addicted smokers were most often men (91.3%) had a higher average age than the lower dependency categories and were more often unemployed. The mean nicotine dependence score was 6.16±2.29. It was not associated with gender. It was, however, significantly associated with low level of education (p=0.001) and advanced age with a weak positive correlation (r=0.182, p<10⁻³). This level of nicotine dependence was, also, significantly associated with a high average number of cigarettes consumed daily (p<10⁻³), a high level of CO exhaled at each visit (p<10⁻³) and a high Hospital Anxiety and Depression scale (p<10⁻³). Smoking cessation requires comprehensive management. Our cost-free unit attracts mostly highly dependent smokers, but also patients with varying level of dependence. Successful quitting depends on factors related to the individual, his environment and the care-quality.

DOI: 10.18332/popmed/165434

Significant role of the nurse in management of pain at oncology patients

Polya Gergova¹, Stela Georgieva², Eleonora Dimitrova²

¹Department of Nursing Surgical Care, Faculty of Health Care, Medical University, Pleven, Bulgaria, ²Department of Social Medicine and Health Management, Medical University, Pleven, Bulgaria

Introduction: Pain is a significant problem in patients with oncology disease. It is a nursing sensitive indicator, so nurses play a key role in successful pain management. Nurses must learn how to effectively communicate with patients to adequately assess and manage pain. The aim of the study is to investigate patients' and nurses' opinion on the complex role of oncology nurse in assessment of oncology pain to patients with oncology disease.

Materials and Methods: The idea about pain assessment examined from a view point of two groups: patients and nurses in oncology departments. Data were collected by direct individual self-administered questionnaire among 67 patients and 49 nurses in the field of oncology pain. Data processing is with Microsoft Office Excel 2016 и SPSS v.25.

Results: Proportion of patients with pain is high (69,1%), when moving (34,3%), at rest (10,4%), at night (10,4%), one of 10 patients has constant pain. In this relation, 76,1% respond affirmatively, the nurse responds immediately to their complaints. Therefore, in more than half of patients, expectations are related to physical pain relief (53,7%). Another part deny pain (35,9%). Patients may deny pain due to their perception of pain as a weakness (64,2%), fears that the disease is progressing (47,8%), sleep problems (67,1%) or even the believe that pain is inevitable part of illness or aging (71,7%). On the other hand, significant part of nurses (67,3%) give information on body position for pain relief. More than a half of nurses (61,2%) monitoring the condition of patients with pain, communication about pain medications confirm 42,9% of nurses. Majority, 77,6% of nurses, assess the necessity of actualization of their communication skills for an adequate pain assessment.

Conclusions: Improvement of nurse's knowledge with pain assessment is needed be aware of the barriers that can interfere it.

Attitude of health professional students as advocates for organ and tissue donation: a community engagement effectiveness study

Jayakumary Muttappallymyalil¹

¹College of Medicine, Gulf Medical University, United Arab Emirates

Background and Objectives: As organ transplantation serves as a rescue method for patients with terminal diseases, there is a huge demand for organ donation world-wide. This study assessed the attitude of health professional students as an advocate of organ and tissue donation. **Material and Methods:** An interventional study design was adopted among the health professional students at a Medical University in Ajman. A validated, self-administered questionnaire was used to assess the attitude of about organ donation before and after a community engagement activity. Ethical approval was obtained prior to this study. Wilcoxon Signed rank test was used to test whether there is any difference between the attitude scores between and after the community engagement activity.

Results: A statistically significant increase in the attitude of the participant towards organ donation (p<0.001) was found. The percentage increase in the attitudinal

score after the community engagement activity was 13.5% in the younger age group and 6.6% among females. The students enrolled under college of Medicine showed a significant increase in the attitudinal scores when compared to the students of other programs. The difference in the median attitudinal scores was statistically significant in students enrolled in programs under College of Medicine and other programs ($p < 0.05$). Conclusions: The study revealed that there was a significant rise in the positive attitude towards organ donation among health professional students after the community engagement activity. Organizing educational activities would improve and create the significance of organ and tissue donation.

Exposure to alcohol and risk of dementia: a systematic review and dose-response meta-analysis

Andrea Rossetti¹, Elena Mazzoleni^{2,3}, Tommaso Filippini^{2,3,4}, Marco Vinceti^{2,3,5}

¹Environmental, Genetic and Nutritional Epidemiology Research Center (CREAGEN), Department of Biomedical, Metabolic and Neural Sciences, Medical School - University of Modena and Reggio Emilia, Modena, Italy,

²Environmental, Genetic and Nutritional Epidemiology Research Center (CREAGEN), Italy, ³Department of Biomedical, Metabolic and Neural Sciences, Medical School, University of Modena and Reggio Emilia, Modena, Italy, ⁴Department of Epidemiology, Boston University, United States, ⁵School of Public Health, University of California, United States

Background: The relation between alcohol intake and cognitive function risk has been established, especially for high levels of exposure. Conversely, the effects at low-moderate levels is still debated and the aim of this study is to characterize the dose-response relation between different degree of alcohol intake and cognitive decline and dementia. **Methods:** We carried out a comprehensive literature search in PubMed and Embase online databases for cohort and case-control studies investigating the association between alcohol intake on cognitive function. For study identification and selection, we will use the Rayyan online open-source program. Whenever possible, we will conduct a dose-response meta-analysis using the new one stage cubic spline mixed-effects model in order to evaluate the nonlinear relation of such association. According to inclusion criteria, we selected studies on human population with no major comorbidities (e.g. CVD, diabetes, immunological deficits and cancer) and without a diagnosis of dementia and MCI at baseline. Further exclusion criteria were binge drinking and alcoholism, in addition to articles in which no exposure dose was reported.

Results: Out of total 3676 articles, we excluded 951 duplicates and after title and abstract screening, we further excluded 2496 records to be subjected to a more accurate analysis. After full-text evaluation, of the 266 resulting articles, we identified 20 eligible studies, with alcohol intake ranging from 0 to 50.4 g alcohol/day and 0 to 4.8 drinks/day. **Conclusions:** The study is currently ongoing; data extraction and prediction of the database for the dose-response meta-analysis will be presented at the Congress.

Health literacy for women released from prison in Brazil: construction and validation of educational material

Patrícia Bonato^{1,2}, Isabel Craveiro¹, Carla Ventura², Réka Cane¹

¹Institute of Hygiene and Tropical Medicine, NOVA Lisbon University (NOVA-IHMT), Lisbon, Portugal, ²Ribeirão Preto College of Nursing, University of São Paulo, Brazil

Background and Objective: Recent research describes the increased risk of death in the first weeks after the release of prisoners, which is higher in those with limited health literacy skills. In the case of women in conflict with the law, studies have identified that limited health literacy skills intensify experiences of marginalization, isolation and shame. In the State of São Paulo (Brazil), the monitoring of people released from prison is carried out by the Egress and Family Attention Centers (EFAC), but there is no direct health intervention in this public facility. We aimed to develop and validate educational material with health guidelines for women released from the prison system who are assisted at the EFAC in a city of São Paulo.

Methods: We designed a multimethodological study with a qualitative approach, whose data will be collected through: an integrative literature review, semi-structured interviews with women released from prison, health professionals and supervisors that assist them (respectively, in the prison unit and in the EFAC), and body mapping. The data will be analyzed using thematic analysis by Braun and Clarke, and the evaluation of the educational material will be carried out using descriptive statistics with the expert judges, as well as with the women released

from prison.

Results: A total of 21 women released from prison, 8 health professionals and 2 EFAC supervisors were interviewed, who described the health needs of these women, the main demand being related to drug use, sedentary lifestyle and risky sexual behavior. The body mapping of 6 women revealed the prison marks left on their bodies and minds.

Conclusions: We expect to elaborate educational material based on the perspectives of the target group, using a participatory approach, which will contribute to increase health status of women released from prison, using language and symbolic meaningful for them.

Trends in prevalence of multimorbidity in Mainland China: a systematic review and meta-analysis

Yang Zhao¹, Yang Zhao¹

¹The George Institute for Global Health, Beijing, China

Background and Objective: Multimorbidity, the presence of two or more mental or physical chronic non-communicable diseases (NCDs), is a major challenge for the health system in China, which faces unprecedented aging of its population. To examine the prevalence and trends in multimorbidity among Chinese adults since 1998.

Methods: Studies regarding the prevalence of multimorbidity in Chinese people published since 1998 were searched in databases of CNKI, Wanfang, and PubMed, and so on. Meta-analysis was performed to calculate the pooled prevalence of multimorbidity based on random effects. Subgroup or Meta-regression analysis was conducted based on survey time, sex, areas, residence place, education level, marital status, and study quality.

Results: A total of 123 papers were included in the analysis, with 7 714 313 participants. The pooled prevalence of multimorbidity in Chinese people was 36.3% (95%CI:32.8% ~ 39.9%). The pooled prevalence was higher in urban than in rural Chinese, and higher in women (36.2%, 95% CI:33.8% ~ 38.5%) than men (33.2%, 95%CI:30.9% ~ 35.5%), but the differences were not significant ($P \geq 0.05$). Between 1998-2019, the increase in multimorbidity did not follow the linear trend. Before 2004, the average prevalence showed 14.5%, with an annual increase rate of around 1.3%. Since 2014, the prevalence of multimorbidity was significantly higher than before ($P \leq 0.001$). Age group difference was found ($P \leq 0.001$), where the prevalence of multimorbidity for Chinese aged 60-79 years old was 38.1% (95%CI: 34.6% ~ 41.5%), followed by those aged 80 years and older, 40-59 years old, and younger than 40 years old.

Conclusions: The prevalence of multimorbidity in Chinese has been rapidly increasing since 2014, and is higher in those aged 60 to 80 years than in other age groups. Therefore, efforts and preventive strategies should be adopted for early screening of multimorbidity in high-risk groups.

Use of health services and physical activity: evidences from a population-based study with the elderly

Edige Santos¹, Bruno Ferreira², Elaine Oliveira¹, Chester Cesar¹, Camila Monteiro², Moisés Goldbaum²

¹Faculdade de Saúde Pública da Universidade de São Paulo Brazil,

²Faculdade de Medicina da Universidade de São Paulo, Brazil

Background and Objective: Healthcare for the elderly represents a challenge for Health Services (HS) at global, national and regional levels. It is known that Physical Activity (PA) during leisure decreases the frequency of HS utilization, leading to a decrease in expenses and being able to help control utilization in public emergency situations. However, the influence that each PA domain can provide is still uncertain. Thus, the purpose of this study was to analyze how the different domains of PA and PA-Total are related to the HS utilization.

Methods: Cross-sectional data from 1019 participants of the Health Survey of the City of São Paulo-Brazil (ISA-Capital), aged 60 years or older (59.7% female; mean age 69.7 ± 7.7 years), were used. Respondents were classified in each domain of PA and PA-Total (IPAQ-long) and HS utilization (preventively, emergency and hospitalization). For the relationship between the PA domains and time of use of the HS, Spearman's correlation was used. Then, controlling for sociodemographic characteristics, lifestyle habits, quality of life and chronic diseases, using weightings for probalistic and complex samples, Poisson regression analysis.

Results: There was a positive correlation between HS-preventive with PA-Total ($r=0.098$; $p<0.01$) and HS-emergency with PA-Transportation ($r=0.158$; $p<0.01$). Thus, the more you practice PA (Total and Transportation) the frequency of HS utilization is decreased. When controlling the analysis, active in PA-total and PA-

leisure have 48% (PR=1.48; 95%CI 1.03-2.13) and 35% (PR=1.35; 95%CI 1.06-1.72) of probability of reporting that they consulted preventive in 3 months or more than their inactive peers. Actives in PA-Total have a 50% (PR=0.50; 95%CI 0.29-0.86) probability of not reporting hospitalization in the last 12 months when compared to inactive.

Conclusions: The importance of PA in Healthcare and the support for the implementation of public health policies aimed at increasing the level of PA in the population are highlighted.

Burden of diseases and costs attributable to dietary risk factors and excess weight in Brazil

Ísis Eloah Machado¹, Aline Siqueira Fogal Vegi¹, Adriana Lúcia Meireles¹, Mariana Carvalho de Menezes¹, Mariana Santos Felisbino-Mendes², Carla Eduarda Faustino Rocha¹, Joice Silva Vieira Leal¹, Larissa Fernanda Fonseca Guedes¹, Luane Pinheiro Rocha², Magda do Carmo Parájara¹

¹Universidade Federal de Ouro Preto, Brazil, ²Universidade Federal de Minas Gerais, Brazil

Background and Objective: Obesity and unhealthy eating are modifiable risk factors for chronic non-communicable diseases (NCDs), a serious public health issue in Brazil. Our objective was to estimate the burden of NCDs and the financial costs for the Brazilian Unified Health System (BUHS) attributable to a diet high in processed meats, sugary drinks, sodium, trans fats, and overweight in 2019.

Methods: The methodology included the estimation of population attributable fractions (PAF), obtained by the Global Burden of Disease 2019, whose parameters are intake of each dietary risk factor (RF), mean body mass index (BMI), size of the RF effect for each NCD, and level of exposure associated with lower mortality risk. The PAFs were multiplied by the DALYs (deaths and years of life lost, adjusted for disability) and hospitalization and procedure costs for treating NCDs, which were obtained from the BUHSs Outpatient and Hospital Information Systems.

Results: Sodium intake was responsible for 30814 deaths (mortality rate per 100,000 - MR: 14.2) and 699119 DALYs (DALY rate per 100000 - DR: 322.7) in Brazil. The consumption of trans fats caused 12,616 deaths (MR:5.8) and 29,905 DALYs (DR:138.0). Processed meat caused 5,494 deaths (MR:2.5) and 192263 DALYs (DR:88.7). The consumption of sugary drinks caused 7657 deaths (MR:3.5) and 233436 DALYs (DR:107.7). A high BMI was attributed to 177940 deaths (MR:82.3) and 5817939 DALYs (DR:2685.2). Regarding costs, US\$57,163,245 was attributable to sodium intake, US\$32711912 to trans fats, US\$29017436 to processed meats, US\$14,116,240 to sugary drinks, and US\$300,056,629 to a high BMI.

Conclusion: Brazilians illnesses and the associated financial burden on the BUHS are strongly affected by the consumption of processed foods and being overweight. The estimates made emphasize how urgent it is to put policies, programs, and other initiatives based on evidence of health promotion and compliance into place and to strengthen them.

Level of physical activity in Belgrade

Svetlana Mladenovic Jankovic¹, Gordana Tamburkovski¹, Aleksandra Andric¹, Marija Markovic¹, Anđelka Grujicic¹, Nevenka Kovacevic¹, Nemanja Stefanovic¹, Milena Jakovljevic¹, Katica Tripkovic¹, Gordana Belamaric¹, Dusanka Matijevic¹

¹Institute of Public Health of Belgrade, Serbia

Background: Regular physical activity is one of major protective factors influencing individual health and contributes to prevention of leading non communicable diseases, quality of life, and wellbeing. Data has shown that 23% of adults worldwide do not meet the global recommendations on physical activity for health. Differences in level of physical activity are often related to age, gender and socioeconomic status. This study was aimed to assess level of physical activity among adult population in Belgrade.

Method: National health survey based on European Health Interview Survey methodology was implemented as cross-sectional study, in 2019, through two-stage stratified sample of 13.589 adult respondents and response rate of 97%. Data were collected by structured questionnaire administered by interviewer. Statistical analysis of data was performed for Belgrade region separately. Prevalence of physical activity in Belgrade was compared with national data in 2019 and data for Belgrade from national health survey in 2013.

Results: About 20% of adult population in Belgrade practice sport or recreational activity at least 150 minutes per week, compared to 11% in Serbia and 12,5% in 2013. Sedentary activities at the workplace are common for 55% people in Belgrade compared to 41% in Serbia and 61,2% in 2013. Excessive sedentary

style is common for 35% people in Belgrade and 23% in Serbia, most often among youngest and oldest adults, more educated and higher socio economic status. Average daily duration of sitting for adults in Belgrade is 5,8 hours and 4,7 in Serbia. Almost 90% of people in Belgrade recognize that regular physical activity is significant factor for their own health.

Conclusion: Although awareness about significance of regular physical activity is high among adult population in Belgrade, prevalence of everyday practice is lower than national data. Additional research is needed in order to identify factors affecting habits related to physical activity.

The relationship between hyperlipidemia and lifestyle factors among adults residing in Ajman UAE: a case-control study

shatha Alsharhatti¹, Maryam Alzaabi²

¹Gulf Medical University, Community Medicine Department, College of Medicine, Gulf Medical University, Ajman, UAE, United Arab Emirates,

²Directorate Medical Service, UAE, United Arab Emirates

Background: Hyperlipidemia is a significant public health issue, however, there is insufficient information on factors that can determine hyperlipidemia among residents of UAE.

Objectives: This study aimed to determine the association between hyperlipidemia and socio-demography and lifestyle factors and to assess determinants of hyperlipidemia among the study population.

Materials and Methods: A case-control study was conducted during the period between January-May 2020, at a Teaching Hospital, Ajman. The study included 91 adults (41 cases and 50 controls) aged 20 years or above, both genders and all nationalities. Consecutive individuals attending the Laboratory Department were approached, those who had signed the informed consent were included. A researcher-administered questionnaire was used., blood samples were collected, and the lipid profile workup was done according to the laboratory standard procedures. IRB approval was obtained. The SPSS software (version 26) was used for analysis. Chi-square test, independent t-test and logistic regression analysis were used

Results: The highest proportion of cases aged ≥ 35 years (87.8%); males (75.6%); Overweight (39.0%); Arab (61.0%); whose average income between 10000 - <20000 (51.2%); married (92.7%); Bachelor or higher level of education (92.7%) and employed (75.6%). The proportions of practicing unhealthy lifestyles were higher among cases than controls for smoking, cigarettes, waterpipe, special diet, and inadequate sleep. Significant associations were found between hyperlipidemia, age ($p=0.009$), marital status ($p=0.007$), and history of hypertension ($P=0.045$) and thyroid diseases ($P=0.038$).

Significantly lower mean values of low-density lipo-protein ($p\leq 0.001$), triglycerides ($p\leq 0.03$) and total cholesterol ($p\leq 0.001$) among cases compared to controls. Age was a significant predictor of hyperlipidemia. The predictors of hyperlipidemia were; age ≥ 35 years, having family history of hyperlipidemia and excessive dietary intake of sugar.

Conclusion: The significant predictors for hyperlipidemia are: Age ≥ 35 years, having family history of hyperlipidemia and excessive dietary intake of sugar.

Association between tooth loss and sociodemographic variables of older people attending community centers of a capital of the southeast region of Brazil

Maria Miotto¹, Adriana Aguiar¹, Caroline Thomes¹, Ana Alvarenga¹, Angelita Mansur¹

¹Universidade Federal do Espírito Santo, Programa de Pós Graduação em Saúde Coletiva Avenida: Marechal Campos. Número: 1468. Cidade: Vitória. Estado: Espírito Santo. País: Brasil. CEP: 29047-105. Brazil

Introduction: Demographic transition is a global phenomenon that reflects the growth of people reaching older age, due to increased life expectancy and a sharp fertility drop. Regarding longevity, it will depend on the opportunities that the health sector can provide to the individual during his/her life.

Objective: To identify an association between tooth loss and sociodemographic variables of older people attending Community Centers.

Methods: Analytical study with cross-sectional design, conducted in Vitória, Espírito Santo, Brazil, with data collection from February to April 2019, developed by three duly trained researchers. The participants were interviewed through structured scripts, previously used in other studies in Brazil, addressing sociodemographic aspects and oral health related factors, the final sample consisted of 402 participants. Descriptive analysis of the data was performed and organized in frequency tables with number and percentage for each of the items

of the research instrument. The Chi-square test was used to evaluate possible associations. A 5% significance level was adopted.

Results: The study showed a high prevalence of tooth loss in the older population. A 54% of the participants lost 11 or more teeth, the vast majority (95.8%) of them had lost at least one dental element. The molar was the most extracted tooth (94.8%), and caries disease was the main cause of tooth loss (69.9%). The factors associated with tooth loss were: gender ($p=0.024$), age group ($p=0.000$), schooling ($p=0.000$), and socioeconomic status ($p=0.000$).

Conclusions: We identified that women, older than 70 years, with up to 10 years of schooling, belonging to classes C/D – E were more affected by tooth loss, evidencing sociodemographic characteristics as determinants of the health-disease process and portray health inequities in the country, since the disadvantaged are the most affected.

DOI: 10.18332/popmed/163882

The Territorial Operative Center: an innovative management for Assisted Hospital Discharges in the health district of Vignola, Modena, Italy

Riccardo Barbieri¹, Federica Casoni², Valeria Menabue², Elena Righi¹

¹University of Modena and Reggio Emilia, Italy, ²AUSL Modena, Italy

Background: As part of the National Recovery and Resilience Plan (NRRP 2021), Mission 6 should provide for the creation of proximity networks, structures of intermediate care and telemedicine in order to improve territorial healthcare: these interventions, regulated by Ministerial Decree 77/2022, will lead to the strengthening and the implementation of Community Houses and Hospitals and to the development of Territorial Operative Centers (COT).

Objective: COT is an organizational model that performs a function of coordination of taking care of the patient and connection between services and professionals involved in different settings. The role of the COT is to facilitate transition from the hospital to the territory and to reduce the risk of readmission and improper use of Emergency Department.

Methods: In the health district of Vignola, COT highlights the importance of building an outlined process for taking care of frail patients on assisted hospital discharges (AHD). The management of this process should consider the peculiarities of territory, which is large and heterogeneous, characterized by both flat areas with high population density and mountainous regions with low population density. COT will be placed inside Vignola's new Community House. An analysis of indicators related to the hospitalization of frail patients will be performed after the introduction of the COT, in order to evaluate its impact compared to the current model and to verify an improvement on AHD.

Results: COT's functions on AHD would include:

- * receive and decode reports from hospital;
- * evaluate health needs through multidimensional assessment, identifying the most appropriate program for each patient;
- * verify the start of the personalised program and monitor its progress over time.

Conclusions: The originality of this project is to evaluate the role of the COT in the improvement of frail patient's journey. If the effectiveness were confirmed, this project should be standardized at the provincial level.

Workplace gender harassment, illegitimate tasks, and poor mental health: hypothesized associations in a swedish cohort

Aziz Mensah¹, Susanna Toivanen², Martin Diewald³, Mahmood Ul Hassan⁴, Anna Nyberg⁵

¹Mälardalen University Sweden, ²Mälardalen University, ³Bielefeld University Germany, ⁴Stockholm University Sweden, ⁵Uppsala University

Background: Workers exposed to gender harassment and illegitimate tasks may experience adverse mental health outcomes such as depression and burnout. However, the longitudinal effects and the complex interrelationships between these variables remain largely unexplored. We therefore investigated the cross-lagged relationships between gender harassment, illegitimate tasks, and mental health outcomes among working adults in Sweden over a period of two years, as well as the gender differences in the cross-lagged effects. Additionally, the study examined whether illegitimate tasks mediated the relationship between gender harassment and negative mental health outcomes over time.

Method: Data were drawn from the Swedish Longitudinal Occupational Survey of Health (SLOSH), covering 2796 working men and 4110 working women in a two-wave analysis from 2018 and 2020. We employed a structural equation model to examine the cross-lagged effects and the mediating effect between gender harassment, illegitimate tasks, and mental health outcomes over time.

Furthermore, we applied a multigroup analysis to determine gender differences in the cross-lagged effects.

Results: The results showed statistically significant cross-lagged (i.e., forward, reverse, and reciprocal) relationships between gender harassment, illegitimate tasks, and mental ill-health (i.e., burnout and depression). There were statistically significant gender differences in these cross-lagged relationships (burnout: $247=106.21$, $p < 0.01$; depression: $247=80.5$, $p < 0.01$). Initial but not later illegitimate tasks mediated the relationship between gender harassment and mental ill-health outcomes over time.

Conclusion: The gender differences in the interrelationships between gender harassment, illegitimate tasks, and mental ill-health outcomes among workers in Sweden indicate that policies, regulations, and interventions that address these exposures in organisations must be tailored to benefit both men and women.

Work history as a life course socioeconomic position and its association with depression in mid to later adult life: a systematic review of the evidence

Eun Kim¹

¹University College London United Kingdom

Background and Objective: Given the challenging economic climate during the past decades, the ageing workers around the world are more likely to have held multiple lifetime occupations and employments. Thus, the longitudinal observation of an individual's composite work and employment trajectories over lifetime can be considered a potential SEP that can explain the mid- to later life inequalities in depression. Yet, the systematic evidence is limited. Here, I present the systematic evidence for the life course work history as an SEP and its association with depressive symptoms of older adults.

Methods: Results were identified from five electronic databases, which were searched to identify studies from the wider discipline as well as epidemiology. Studies that examine the effect of varying labour force participation pattern over lifetime on later adult life depressive symptoms were identified. The four search concepts were: Concept 1 (Older adults, Age 45+, Midlife to later life), Concept 2 (Depression, depressive symptoms), Concept 3 (Employment history, labour force participation, employment status, adverse career characteristics), Concept 4 (Longitudinal analysis, life course analysis).

Results: The search found 12,166 studies meeting the eligibility criteria, of which 7,008 studies were screened based on their titles, and of which 427 studies screened on their abstracts. 270 full-text articles were assessed for eligibility after screening, and 47 studies were quality assessed based on the risk of bias tool that was derived from the various checklists and criteria used in other systematic review.

Conclusion: Results suggest that lifetime employment continuum has an impact on the depressive symptoms of older adults, and policy strategies that target populations with specific course of employment history is needed, especially in the treatment of depression.

DOI: 10.18332/popmed/164081

Epidemiology of abdominal obesity among adults in rural and peri-urban Bangladesh

Mohammad Rahman Sarker¹, Md Rahman², Michiko Moriyama², Mohammad Chisti³, Shakila Banu¹, Taiyaba Ananta⁴, ASG Faruque²

¹Technical Training Unit, icddr,b, Dhaka, Bangladesh Bangladesh, ²Graduate School of Biomedical and Health Sciences, Hiroshima University, Japan

Japan, ³Nutrition and Clinical Services Division, icddr,b, Dhaka, Bangladesh Bangladesh, ⁴Govt. College of Applied Human Science, Dhaka, Bangladesh

Background and Objective: Bangladesh is experiencing fast epidemiologic and demographic shifts, as well as changes in lifestyle, food, and physical activity. A small number of researches on abdominal obesity have been carried out in Bangladesh, most of which involved hospital-based and urban populations. We conducted this study to investigate the prevalence of abdominal obesity and its associated factors among rural and peri-urban Bangladeshi populations.

Methodology: This cross-sectional study was conducted in the Mirzapur subdistrict of Bangladesh during January to June 2020. Adult participants were randomly selected from the Demographic Surveillance System (DSS). Interview using a semi-structured questionnaire, physical examination, and anthropometric measurement were done followed by blood and urine testing. According to the World Health Organization, a waist circumference of 94 cm in men and 80 cm in women was considered abdominal obesity.

Results: The DSS enrolled 928 patients; 872 (94.0%) of them completed the study

procedure and were included in this analysis. The overall age in years was 48.2 with a standard deviation of 16.4. Prevalence of abdominal obesity was 39%. In multivariable analysis, significant positive associated factors for prevalent abdominal obesity included those aged ≥ 46 years [adjusted odds ratio (aOR) 2.72; 95% confidence interval (CI) 1.21-6.13], hypertension (aOR 1.18; 95% CI 1.28-2.76), hypertriglyceridemia (aOR 2.22; 95% CI 1.49-3.31), female (aOR 7.99; 95% CI 3.58-17.87); however, negative associated factors included undernutrition (aOR 0.03; 95% CI 0.01-0.09), present smokeless tobacco user (aOR 0.59; 95% CI 0.38-0.92) and having no formal schooling (aOR 0.58; 95% CI 0.38-0.89). Conclusion: Our findings reveal that patients living in rural and peri-urban areas have a higher prevalence of abdominal obesity, in which age ≥ 46 years, hypertension, hypertriglyceridemia, and being female have a significant role. Policymakers should step up intervention to reduce abdominal obesity in light of the significant association.

Patient experience after a hip fracture in relation to an empowerment-oriented intervention

Lars Tobiesen Pedersen¹, Bjarke Viberg², Inge Hansen Bruun³, Heidi Klakk Egebæk⁴, Pernille Tanggaard Andersen⁵

¹Department of Physical Therapy and Occupational Therapy, Lillebaelt Hospital, University Hospital of Southern Denmark, Odense, Denmark
²Department of Regional Health Research, University of Southern Denmark, Odense, Denmark Sygehusvej 24, 6000 Kolding, Denmark, ³Department of Orthopaedic Surgery and Traumatology, University Hospital of Southern Denmark, Odense, Denmark, ⁴Department of Physical Therapy and Occupational Therapy, Lillebaelt Hospital, University Hospital of Southern Denmark, Odense, Denmark, ⁵Center for Clinical Research and Prevention Denmark, ⁶Health sociology and promotion, Department of Public Health, University of Southern Denmark

Background: The consequences of a hip fracture have been well documented and approximately 50% of hip fracture patients have a substantial reduced function one year after their fracture. An increased focus on how to help adults +65 years to remain active and regain control over their everyday life is important. Rehabilitation of Life[®] is an empowerment-orientated hip fracture intervention focusing on continuous rehabilitation and care, progressive strength training and optimised communication and cooperation between sectors in Denmark. The objective of this study is to understand and explore adults +65 years experiences related to 'Rehabilitation of Life' - an empowerment-orientated hip fracture intervention.

Method: A qualitative design was applied. Data was generated from semi-structured interviews using a pilot tested interview guide. A purposeful sampling from patients included in the intervention 'Rehabilitation of Life' were selected. In total 18 hip fracture patients were interviewed until data saturation. A qualitative content analysis was guided by Graneheim and Lundmans concept.

Results: The analysis resulted in five themes, which the participants emphasized as important to their rehabilitation: Getting information and care when hospitalizes, Early visit from health staff after return to own home, The social aspect of training together with others, Rehabilitation provide by skilled and empathic staff and The reassurance of follow ups after returning to their own home. The content of the 5 themes indicates that adults +65 generally has experienced their rehabilitation after a hip fracture as motivating, reassuring, and has helped them return to their normal everyday lives.

Conclusion: The findings contribute with important knowledge about hip fracture patients experiences related to participating in an empowerment-oriented rehabilitation and how it could help the patients to remain active and being able to regain control over their everyday life after a hip fracture.

Association between glycemic levels and a frailty syndrome in the elderly of the longitudinal study of adult health (elsa-brasil)

Elizabeth Barbosa¹, Rosane Griep², Elizabeth Barbosa¹, Rosane Griep², Cláudia Szlejf², Maria da Fonseca¹, Sandhi Barreto³, Rosa Telles³, Bruce Duncan³

¹National School of Public Health, Oswaldo Cruz Foundation Brazil,

²Laboratory of Health and Environmental Education, Oswaldo Cruz

Foundation, Brazil, ³Federal University of Minas Gerais Brazil

Some studies have reported the relationship between Frailty Syndrome and Diabetes Mellitus (DM), however, there is a lack of studies exploring the relationship between frailty and HbA1c. Thus, the objective of this article was to analyze the association between the of glycemic levels in around 10 years of follow-up and

the prevalence of the frailty syndrome. Data are from the Longitudinal Study of Adult Health (ELSA-Brasil), a multicenter cohort of Brazilian civil servants. Frailty phenotype was defined with five criteria: fatigue, low physical activity, unintentional weight loss, slow walking speed and low handgrip strength. The presence of one or two of these criteria indicated a pre-frailty condition, and the presence of three or more indicated a frailty condition. The glycemic levels clusters had its defined through cluster analysis considering the HbA1c measurements in the three waves of the study: baseline: 2008-2010; wave 2 (2012-2014) e wave 3 (2017-2019). Data from 4,649 participants aged > 60 years were included. From the cluster analysis, 4 clusters of glycemic levels were identified (HbA1c 5.4% and 6.6% and 8.9%). Associations were estimated using multinomial regression models (crude and adjusted for sociodemographic variables and for hypertension). Compared to the elderly classified in the "HbA1c.

"CODICE ARGENTO": dedicated care pathway for the frail elderly in the emergency department of cristo re hospital

Martina Sapienza¹, Anna Bonini², Giovanni Brandimarte³, Lucia Matarazzo⁴, Alessandro D'Avino³, Pomes Michele⁴, Francesca Pozzi⁴, Piera Benedetti⁵, Gabriella Nasi⁵

¹Ospedale cristo re Italy, ²Controllo di Gestione Ospedale Cristo Re Roma - Gruppo Giomi Italy, ³UOC Medicina Ospedale Cristo Re Roma - Gruppo Giomi Italy, ⁴Pronto Soccorso Ospedale Cristo Re Roma - Gruppo Giomi Italy, ⁵Direzione Sanitaria Ospedale Cristo Re Roma - Gruppo Giomi, Italy

Background and Objective: The Emergency Department (ED) of Cristo Re Hospital in Rome, to provide the best care for the elderly patient (>75), from January 2021, a multidisciplinary team has been implemented and the Codice Argento has been introduced in the ED for a dedicated pathway for these patients. With this code, such users can be identified very early through a score of a few questions to define a set of defined and validated parameters. In 2022, we implemented the outcomes already identified to increase the quality and safety of care of this target group of patients.

Methods: We evaluated data of ED accesses for >75 years old (first 9 months of 2021 vs first 9 months of 2022).

Results: In 2021, accesses were 2077, for a total of 21% admissions. In the same period of 2022, accesses were 2200, for a total of 17% hospitalizations. Analysis of the data showed:

* increase:

* of accesses in patients ≥ 75 years old;

* of % total accesses vs % accesses ≥ 75 yr old (13.39% in 2021 vs 13.70% in 2022);

* of home discharges (74% in 2021 vs 76% in 2022);

* reduction:

* of the % of hospitalizations (21% in 2021 vs 17% in 2022);

* of the length of stay in the PS for orange, blue and green codes;

* of admission days (faster and more correct clinical framing in the ED);

* of the behavioral disorders that often accompany hospitalization.

Conclusion: The shared, facilitated and multidisciplinary approach to the frail elderly patient, has improved the outcomes considered by facilitating hospital pathways. We aim to continue monitoring of outcomes, to continue assistance to the frail elderly with the support of telemedicine and teleconsultation by collaborating with the the GPs (e.g. schedule meeting) and to increase the prescription of specialist follow-up.

Translation, cross-cultural adaptation and content validity of the model disability survey for the Brazilian population

Núbia Lima¹, Núbia Lima¹, Denise de Araújo², Erika Silva, Amanda Medeiros¹, Shamy de Castro³, Indyara Morais⁴, Carla Sabariego⁵, Rodrigues Santos¹, Romário Fonseca¹, Dellis Almeida¹, Monalisa França¹, Ubiratan Junior¹, Karolinne Monteiro¹

¹UFRN - Federal University of Rio Grande do Norte UFRN - Federal University of Rio Grande do Norte Faculty of Health Sciences of Trairi, Federal University of Rio Grande do Norte, Vila Trairi St, 435, Centro, Santa Cruz, 59200-000, Rio Grande do Norte, Brazil. Brazil, ²UFRN - Federal University of Rio Grande do Norte, ³Federal University of Ceará, ⁴University of Brasília (UnB) University of Brasília (UnB) UnB - Brasília, DF, 70910-900, Brazil. Brazil, ⁵University of Lucerne - Luzern University of Lucerne Frohburgstrasse 3, 6002 Luzern, Switzerland Brazil

Background: Although morbidity and mortality are important, health indicators related to functioning should also be incorporated into Brazilian data collection

systems. In this sense, the world health organization designed the model disability survey (mds) based on the biopsychosocial model of the international classification of functioning, disability, and health (icf).

Objective: To translate, cross-culturally adapt and analyze content validity of the Brazilian version of the mds.

Methods: This cross-sectional was conducted in five steps: Initial translation, synthesis of translations, back-translation, review by an expert committee, and pre-test. For the pre-test, we included people of both sexes aged over 18 years, with or without disabilities and formal education, and with cognitive ability to answer the survey.

Results: Mds was considered with 474 items, and 1,896 analyzes were performed according to four equivalences. Of these, 17.25% were partially adequate and inadequate by specialists. A total of 160 items were discussed with other members of the committee. In the pre-test, 22 interviews were conducted in rio grande do norte (73.3%), four in ceará (13.3), and four in paraíba (13.3%), with average duration of 123 minutes. The target audience was 30 participants, single, young adults, self-declared black or brown, with at least technical education. Most were active workers and lived and lived with three family members. Out of one hundred twenty-seven health conditions cited, the most frequent were anxiety and back pain/herniated disc. Answers were analyzed and 63 items needed adjustments; however, only two were sent to the expert committee because they presented a content validity index of < 0.80.

Conclusions: The mds instrument was translated into Brazilian portuguese, cross-culturally adapted for the Brazilian population, and presented adequate content validity. The Brazilian version was entitled mds-Brazil.

Language and functioning by icf and slp group intervention: giving voice to people with parkinson disease, a Brazilian experience

Regina Chun¹, Amanda Zerbeto¹, Thais Piccoli¹

¹University of Campinas (Unicamp) Brazil

Background and objective: Parkinson Disease (PD) is a chronic progressive neurodegenerative disease characterized by motor impairments and communication difficulties. The International Classification of Functioning, Disability and Health (ICF/WHO) allows studying the functioning of people with PD. The aim is to investigate language, functioning in PD and the effects of group speech-language pathology (SLP) intervention on the perception of the people with PD, taking the ICF as a conceptual basis.

Method: Cross-sectional research, approved by the Ethics Committee, with 10 participants with PD, in SLP group at a specialized care center in Brazil. An interview script and a self-administered questionnaire were developed to collect self-perception in the 33 ICF categories, answered by the participants in three group meetings, approximately 35 minutes each, with the researchers, videotaped. Experience in the ICF classified the answers in the same categories. To establish a reference parameter, SLP with experience in the ICF (judges) classified the answers in the same categories.

Results: The participants indicated impairments in Body Functions (voice, articulation, fluency and rhythm of speech, involuntary movements), difficulties in Activities and Participation (speech, conversation, fine use of the hand, walking, dressing, performing household chores, and recreation and leisure) and barriers in Environmental Factors. In 60% of the cases, the agreement between participants and judges was slight, in 30% it was fair, and in one case (10%) was it strong.

Conclusion: The results regarding the functioning of people with PD in their perception assume an original character, giving voice to the people themselves, in addition to bringing important subsidies for person-centered care, expanding the biomedical vision centered on the disease, for a biopsychosocial approach proposed by the ICF/WHO.

Hospitalizations for malnutrition in Brazilian older adults

Mayara Araújo¹, Thaiza Nobre¹, Vilani Nunes¹, Adriana Oliveira², Felismina Mendes³, Gilson Torres¹

¹Federal University of Rio Grande do Norte Brazil, ²Catholic University of San Antonio of Murcia Spain, ³University of Évora Portugal

Background and objective: Some conditions are considered sensitive to primary health care (PHC) as nutritional deficiencies, and it is an indicator of access and the quality of care offered in the PHC. This study aimed to describe malnutrition hospitalizations in Brazilian older adults and to verify the temporal evolution of hospitalizations in the five regions.

Methods: This is a descriptive and ecological study of time series, based on

secondary data obtained from the System of Health Indicators and Monitoring of Older Adults Policies (SISAP-Older adults). We used data referring to 2000 to 2019 regarding hospitalizations due to nutritional deficiencies considered avoidable that include the categories E40-E46 and E50-E64 of ICD-10, in men and women aged 60 to 74 years in five Brazilian regions. Data were analyzed descriptively using the software Microsoft Excel®.

Results: There were 232,592 malnutrition hospitalizations in Brazilian older adults between 2000 and 2019, and we observed a decrease of 44.6% in the number of hospitalizations. The Southeast and Northeast regions had the highest number of hospitalizations, corresponding to 46.5% and 30.2%, respectively. The North region showed an increase of 16.6% in the number of hospitalizations, while the Center-West region showed a reduction of 52.7%. Regarding gender, 59.5% of hospitalizations were male. The Southeast region concentrated the highest number of hospitalizations for both sexes, 43.3% of women and 48.7% of men. A greater reduction was observed in women's hospitalization in the Northeast region (-58.5%) and men in the Midwest region (-52.2%).

Conclusion: A tendency to decrease malnutrition hospitalizations was observed in Brazilian older adults. Although, health actions are needed to strengthen food and nutritional surveillance in primary health care to reduce the risk of hospitalization in the older population.

DOI: 10.18332/popmed/164319

Changes in physical activity and perception of weight gain during covid-19: elsa-brasil cohort

Maria Bisi Molina¹, Jordana Siqueira¹, Carla de Oliveira Aprelini², Haysla Martins¹, Taisa Sabrina¹, Maria Bisi Molina²

¹Federal University of Espirito Santo Brazil, ²Federal University of Espirito Santo

Background and objective: The COVID-19 pandemic led to social isolation as a non-pharmacological intervention measure. Despite being an effective strategy for reducing transmission of the disease, research has indicated the occurrence of changes in lifestyle and negative repercussions on the health of populations. The objective was to associate changes in physical activity and the perception of weight gain during the COVID-19 pandemic in ELSA-Brasil.

Methods: Longitudinal study using the second follow-up of the cohort (2017-18) and Onda-COVID (2020-21) that included civil servants residing in 5 Brazilian capitals. Socioeconomic and lifestyle data were collected. Leisure-time physical activity (LPA) was measured using the International Physical Activity Questionnaire, converted into multiples of metabolic equivalents (METs/week) and classified into tertiles of change. The association between changes in LPA and perceived weight gain was verified by obtaining crude and adjusted odds ratio estimates and 95% confidence intervals using binary logistic regression.

Results: The final sample consisted of 3,940 individuals, 58.8% women. Participants who reported weight gain had lower mean age, diet quality and LPA, and higher mean body mass index. When analyzing the LPA change delta between assessments, there was a reduction in the mean METs/week in both genders ($p < 0.001$). Being in the low tertile of LPA change increased the odds of perceived weight gain by 1.5 (95% CI 1.04-1.45) and 1.6 95% (CI 1.04-1.45) times among women and men, respectively.

Conclusion: Women and men in the lowest tertile of LPA change were more likely to perceive weight gain during COVID-19.

Preliminary data of the model disability survey in Brazil: functioning module

Denise de Araújo¹, Núbia Lima¹, Gyovani Lima², Liane Macedo¹, Aline Fernandes¹, Shamyr de Castro³

¹UFRN - Federal University of Rio Grande do Norte Faculty of Health Sciences of Trairi, Federal University of Rio Grande do Norte, Vila Trairi St, 435, Centro, Santa Cruz, 59200-000, Rio Grande do Norte, Brazil. Brazil, ²UFRN - Federal University of Rio Grande do Norte, ³Federal University of Ceará

Background: The model disability survey (mds) is a tool based on the biopsychosocial model and aims to measure functionality and human disability. the mds-brasil module (4000) has topics related to peoples ability and performance to carry out daily activities considering physical, psychological and socio-environmental conditions.

Objective: To describe data from the pre-test phase of module 4000 (functionality) of the model disability survey brasil (mds-brasil) instrument.

Methods: This study included 30 individuals residing in northeastern Brazil, with

or without disabilities, who were cognitively able to respond to the questionnaire, and participants who refused or gave up the interview were excluded from the study. The participant was contacted for invitation and appointment of the date and place of the interview, where the questionnaire, the manual and the mds-brasil presentation cards were used, translated and cross-culturally adapted to the Brazilian population. The responses from module 4000 of the mds-brasil were analyzed.

Results: Of the 30 participants, 73.3% lived in rio grande do norte, 13.3% in ceará and 13.3% in paraíba. Females predominated with 83.3%, single 56.7%, 30% had higher education, 53.3% were considered brown and 26.7% worked for an employer. Some difficulties were reported by them, among which 33.3% of the participants said they had a problem walking short distances, 20% to carry out activities using their hands, 16.7% to do personal hygiene and get dressed, 53.3% for seeing from afar, 73.3% for feeling pain in everyday life, 53.3% for sleeping, 50% revealed difficulties in understanding and 53.3% in remembering to do important things.

Conclusion: The results of the pre-test allowed a first contact with the community and, through module 4000 of the mds-brasil, it was possible to identify the main limitations of activities and social participation that influence human functionality.

Swap relations and sense of justice for distribution in agricultural families

Astrid Seltrecht¹, Vivienne Thomas², Astrid Seltrecht¹, Vivienne Thomas¹

¹University of Magdeburg FHW, Institut 1 Otto-von-Guericke-Universität Magdeburg Zschokkestraße 32 39104 Magdeburg Germany, ²University of Magdeburg, Magdeburg, Germany

Background and objective: The special structure in old-age security differs agricultural families from other family constellations, for example challenges exist for the upcoming generation, which automatically is responsible for the financial securing of the elder generation when taking over the enterprise. In this analysis the question was pursued, which specifics underlie for families of agricultural economy concerning age and aging processes in the context of intra-familial dependencies.

Methods: The data corpus consists of 25 guided interviews with a high narrative share, which were evaluated with the Grounded Theory (Strauss/Corbin 1996). Within nine families representatives from a minimum of two generations were surveyed.

Results: The main category generation-specific attribution of meanings of the objective contract presents itself within two phenomena, which appear in the perspectives of both generations involved, however one of each is highlighted in one of each generations:

Conclusion: Against the background of the empiric outcome it can be stated that the attribution of meanings of technically objectively regulated issues turn out differently according to a specific generation. The living together is perceived as a swap relation which is experienced more or less satisfying depending on the design. The elder share may utilize services from the younger generation, may demand or ask for services, because in return the elder share have transferred the estate to the younger generation, making it possible to keep up family traditions or leave behind an enterprise in dept and need of redevelopment. For both generations it is progressively a matter of fair distribution in the context of this intra-generational swap relation. However the sense of justice comes out differently in specific generations. Intra-generational dependencies pose a claim.

Adult Health Experience with Autism Spectrum Disorder: Self Perception of Functioning in Brazil

Regina Shon Chun¹, Fernanda Silva¹, Regina Shon Chun²

¹Campinas State University - UNICAMP R. Tessália Vieira de Camargo, 126 - Cidade Universitária, Campinas - SP, 13083-887 Brazil, ²Campinas State University - UNICAMP

Justificativa e objetivo

O Transtorno do Espectro do Autismo (TEA) é uma condição do neurodesenvolvimento caracterizada por dificuldades persistentes na comunicação e interação social e padrões de comportamento e interesses restritos e repetitivos. Os sintomas podem causar resultados funcionais adversos na vida doméstica, nas relações sociais, bem como dificuldades nas atividades escolares e de trabalho; dependendo de fatores como nível de desenvolvimento, características pessoais, suporte familiar e tratamentos. Funcionalidade e participação social de adultos com TEA são fundamentais para sua qualidade de vida. No entanto, estes ainda

são temas relativamente negligenciados na literatura. O objetivo deste estudo é investigar o funcionamento de adultos com TEA, com diferentes níveis de suporte, usando o World Health Disability Assessment Schedule 2.0 (WHODAS 2.0).

Método

Trata-se de um estudo descritivo de corte transversal. A amostra contém 65 indivíduos diagnosticados com TEA no Brasil, com idade entre 18 e 25 anos, a maioria do sexo masculino, com pelo menos uma comorbidade e renda familiar mensal não superior a 1.128 USD. O WHODAS 2.0 avalia a funcionalidade e a incapacidade nos domínios da cognição, mobilidade, autocuidado, convivência, atividades da vida e participação. Além disso, dados sociodemográficos e clínicos foram coletados por meio de uma pesquisa semiestruturada.

Resultados

A média amostral (m) para funcionalidade foi de 49,84 com desvio padrão (dp) de 17,4. Do maior para o menor, os escores de funcionalidade/incapacidade por domínio foram: convivência (m:66,9; dp:22,2), atividades da vida (m:63,7; dp:23,8), participação (m:56,4; dp:20,0), cognição (m:48,7; 18,5), autocuidado (m:27,2; dp:22,4) e mobilidade (m:33,1; dp:23,4). A correlação cruzada entre os domínios foi positiva e maior entre os domínios de participação e outros.

Conclusão

Os resultados sugerem que o nível de participação está relacionado com a funcionalidade na convivência, atividades de vida e domínios da cognição. A deficiência em todos os domínios está alinhada com o comprometimento cognitivo-comportamental e de comunicação dentro do TEA. Esses achados são importantes para o melhor delineamento de políticas de saúde e podem contribuir para promover uma melhor assistência à saúde de pessoas com TEA no Brasil e em outros países semelhantes.

The actions performed by the sesc women's health team to the city of Conceição de macabu, in a partnership between sesc and the city hall

Thais Madeira¹, Andreia Bizzo¹, Suzana Santos², Denise Anjos³

¹Sesc Rio Brazil, ²Sesc Rio, ³Sesc RJ Brazil

It was held from January to April 2022, in Conceição de Macabu - Rio de Janeiro. The objective is to report the data and experience of the SESC Womens Health Project with the local population. The project offered joint actions, with: mammography exams, preventive exams and Health Education.

The report was built from the activities experienced by the Womens Health team, whose results were apprehended through a questionnaire, to identify, plan and execute health actions based on local norms. We started with a quantitative investigation, allowing us to evaluate the data obtained through the questionnaires. The next step was the qualitative method, which related the data to the initial investigation.

Total assistance in Health Education: 883; mammography exams: 1029; preventive exam: 412. After data collection, we noted that among the women who underwent mammography, 43.15% declared having Systemic Arterial Hypertension (SAH), surpassing the 33.82% who said they did not have SAH. 23.03% did not answer or did not know. Age, skin color, among others, were also evaluated so that we could profile the women assisted.

From the data obtained through the questionnaires, meetings and examinations carried out, we realize the importance of the SESC Womens Health Project, serving the local population and collecting data that can help them to implement effective prevention practices and change habits, provide improvements in womens quality of life.

The actions carried out were fundamental contributions to prevent and encourage health care, allowing the elaboration of practices, guiding women and helping them in the dissemination of knowledge. It is important to draw attention to the high rate of hypertensive women, and with the continuation of the study, a brief evaluation of the effectiveness of the actions developed is expected, verifying the profile and health habits, to expand access to public health services in a region.

Towards a just transition: enabling older populations to mitigate the impact of climate change and maintain wellbeing

Sally Davis¹, Sadiq Bhanbhro², Mei Fang³, Andrew Sixsmith⁴

¹Advanced Wellbeing Research Centre, Sheffield Hallam University, United Kingdom, ²Centre for Applied Health and Wellbeing Research, Sheffield Hallam University, United Kingdom, ³School of Health Sciences, University of Dundee, United Kingdom, ⁴Department of Gerontology, STAR Institute, Vancouver, Canada

Background and Objective: The COVID-19 pandemic demonstrated the vulnerability of older adults through the number of excess deaths across the globe. However, this finding has also demonstrates the importance of building resilience in older communities and has shown the strength, and capacity of older people although this varies widely across geographies, and social and economic determinants. There is now a need to re-imagine a response to social and environmental challenges as experienced and perceived by older adult populations. The 'just transition' is a reference to systems thinking required to engage and enable older populations and communities to de-carbonise, contribute to greener living solutions and participate fully in sustainable development of communities and cities, especially in relation to digital technology as an enabler to health and wellbeing. AGE-WELL is a unique Canadian network that brings diverse stakeholders together to develop technologies and services for healthy aging and the Advanced Wellbeing Research Centre (AWRC) in the UK is developing implementation method focussed on population health, wellbeing, and reducing inequality and the impact of climate change. Combining expertise and experience of both these internationally reputable organisations and its members, the aim of the workshop is to identify capability and assets for further transformative learning and research that recognise the environment as a prerequisite to living well in old age and is based on UN Sustainable Development Goals and ecocentrism. **Methods:** This workshop will use appreciative inquiry [AI] to identify assets through questions and dialogue that help participants identify how older populations engage through their communities, organisations, or households to understand the causes and consequences of climate change. AI is based on a recognised process (the 4D's model) to enable constructive critical thinking and clarity about opportunities for social and policy development. Reference will be made through different scenarios, to climate change and climate shocks in the global south and to variation in social and economic determinants that differentiate older adult circumstance and environmental impact.

Results: The workshop will identify a 'minimum-specification'; a vision and set of principles by which researchers and public health professionals will engage with older populations and to identify mechanisms and outcomes for environmental and social sustainability. This can related to a range of continuing participation in communities and households and user need including health and care services. The outcome of the workshop will be shared across participants' networks and published as an implementation strategy for research that implements the 'just transition' for and with older adults. We hope to foster academic networking and further academic collaboration on digital and technological development for population wellbeing.

Conclusions: The workshop aims to contribute to support transformative transdisciplinary research that enables implementation and informs planetary and public health and wellbeing. The focus on assets and whole systems approaches that promote inclusion and participation are aligned to the minimum requirements for the social and environmental determinants of health alongside clean air, safe drinking water, sufficient food and secure shelter in old age.

Popul. Med. 2023;5(Supplement):A96

DOI: 10.18332/popmed/165474

Epidemiological transitions in a life-course perspective: challenges and opportunities for healthy ageing

Daniela Soitu^{1,2}, Giansanto Mosconi³, Laura Cucinella⁴, Giacomo Vigezzi³

¹Department of Sociology and Social Work, Universitatea Alexandru Ioan Cuza, Romania, ²EC2U Alliance, Romania, ³Department of Public Health,

Experimental and Forensic Medicine, Università degli Studi di Pavia, Italy, ⁴Department of Clinical, Surgical, Diagnostic and Paediatric Science,

Università degli Studi di Pavia, Italy

Population ageing is perceived as both a challenge and a social problem at worst. Since health trends show increasing disparities, understanding epidemiological transitions and exposures (i.e., social, environmental and biological factors) that summing up across life affect the chance of healthy ageing is a crucial aim for health professionals and researchers. Being able to detect early markers of physiological compensation and social or behavioural adaptations offers opportunities for timely interventions to optimise health promotion and prevention. The workshop will be structured as follows. First, an integrative life-course approach, its challenges and opportunities will build the ground of the presentation. Based on the activity of the EC2U Alliance Virtual Institute for Good Health and Well-being, a comparative approach of the targets associated with the UNSDG3 will stress the protective and risk factors for significant stages of life. Associated social and economic determinants will be envisaged as challenges and opportunities in national and European contexts. By mirroring strengths and weaknesses, the presentation will invite the audience to open the integrative lens in approaching epidemiological transitions. Secondly, we will present data exploring the impact

of leaving parents' homes and starting University for young adults. Using a cross-sectional online survey on university careers, behavioural risk factors, and psychological well-being using validated scales, we investigated students' health status changes. From a 1500-sample, we appreciated the associations between mental health and health behaviours with the final aim of promoting positive adaptations during this phase, which may significantly impair young adults' future life pathways. In the third contribution, we will focus on the role of reproductive milestones in women as modulators of future well-being and opportunities to implement primordial preventive strategies for healthy ageing. Reproductive history, including menstrual pattern, pregnancy complications, menopause timing and duration of reproductive lifespan, offers valuable information to individualise risk assessment in a gendered-oriented approach. In this view, we will report data exploring the impact of reproductive history on cardio-metabolic health in a sample of midlife women transitioning through menopause, highlighting the importance of the reproductive fil rouge in modulating health and diseases in a life-course perspective. The fourth panellist will open up with the health impact of the transition to retirement, which results in a complex set of adjustments, posing both threats and opportunities for physical and mental health. Health behaviours and mental health changes appeared to be among the most relevant mediators affecting life years after the withdrawal from work. Exploring different databases (e.g., SHARE, INAPP Plus), we collected original data to evaluate labour and retirement-associated determinants' role in the well-being of European and global elder populations. The workshop, bringing together experts with topic knowledge on ageing, will provide answers on how to design a culture for well-being across the whole lifespan and how to conduct assessments and measure success. In the end, we will engage in a fruitful discussion with the audience on the data presented and practical public health implications, exploring how they can inform critical policy debates addressing evidence-based prevention strategies for healthy ageing at the global level.

Supporting antimicrobial stewardship improvements in a Zambian rural health post through education and digital training

John Gannon¹, Kerry Greenan², Eleanor Richards², Tom Neale², Fiona Neale², Olivia Duffy², Hannah Raval², Elizabeth Hill², Eunice Sinyemu³, Ben Margetts³, Rachel Lynch³

¹On Call Africa, World Federation of Public Health Associations, Ireland, ²On Call Africa, United Kingdom, ³On Call Africa, Zambia

Background and Objective: Overprescribing of antibiotics in rural low-resource healthcare settings in Sub-Saharan Africa is common. Volunteers with a non-governmental organisation (NGO) in Zambia's Southern Province created and delivered interventions in partnership with local healthcare staff, with the aim of sustainable improvements in antimicrobial stewardship in a rural health post which serves 25,000 people.

Methods: Antibiotic usage in clinics was measured at three intervals over 16 months (April 2021, March 2022, August 2022). Chart reviews evaluated compliance with national guidelines in decision to prescribe and in choice of antibiotic. Data collection and analysis was approved by the Zambian Ministry of Health. After Audit 1, mentoring sessions were carried out over five weeks by volunteers for staff and patients, including live feedback during consultations. After Audit 2, educational resources were produced including infographics on antibiotic resistance (translated to local language Tonga) and a summary of the Zambian Standard Treatment Guidelines. Staff were also trained to use a free digital stock management system using a tablet device, with offline and online functionality and linked with the District Health Office, aiming to improve consistency of medication supply.

Results: A total of 340 consultations were reviewed over the three audits (240, 50 and 50). Ratio of overprescription (antibiotics prescribed: indicated) reduced from 212/59 (3.59:1) to 33/11 (3:1) to 25/9 (2.78:1). Correct antibiotic choice varied from 14/59 (25.9%) to 1/11 (9%) to 3/9 (33%).

Conclusions: There was a steady decline in antibiotic overuse following mentoring and educational interventions. Incorrect choice of antibiotic was mostly reported as due to severe lack of medication availability. A key challenge will be continued improvement in antibiotic stewardship standards and reducing stockouts in this Zambian health post without ongoing oversight from the NGO. Findings can inform implementation of similar projects in other rural low-resource healthcare settings.

Dispense of non-prescribed antibiotics without prescription from pharmacies in Jhelum: a cross-sectional survey

Saeed Ahmad¹, Fahmeeda Idrees¹

¹Health Services Academy, Islamabad, Pakistan

The main power source for antibiotics is local pharmacies. Our goal was to evaluate the expertise of pharmacy employees and the distribution of non-prescription antibiotics. In Punjab, Jhelum, we carried out a cross-sectional study from April 2022 to July 2022. We employed a conscience, structured, pretested, and authorized multilingual questionnaire and performed statistical analysis using chi-square tests. The study received responses from 100 pharmacy wholesalers in total (95%); 69.4% of them were male and between the ages of 20 and 50. The majority of participants about 34.9% said that community pharmacists frequently supply non-prescription antibiotics, and 53.7% said they were qualified to do so. Approximately 46.3 percent thought this was a role in the rise of antimicrobial resistance. None of the respondent thought that this approach encouraged illogical antibiotic use, and partial (58.0%) thought that antimicrobial resistance was a problem for public health. Only 58.0 % of respondents said they advised patients to seek medical advice before using antibiotics, and 19.1 % said their dispensing procedures minimized the financial patients burden. A little over 44.0 % of pharmacy owners claimed to be knowledgeable about using antibiotics. The most common class of antibiotics given out without a prescription was nitroimidazole. The distribution of injectable and widespread antibiotics may represent a risk to the ability to treat infections. The distribution of antibiotics without a prescription is related to staff knowledge deficiencies. This improper practise has to stop right away.

DOI: 10.18332/popmed/164967

Group B Streptococcus maternal colonization, vertical transmission, serotype distribution and antimicrobial resistance pattern in sub-Saharan Africa: a systematic review and meta-analysis

Minyahil Boltana^{1,2}

¹Armauer Hansen Research Institute, Ministry of Health, Ethiopia, ²Center for Evidence Based Health Care, Institute of Health, Jimma University, Ethiopia

Background: Although GBS associated maternal, perinatal, and neonatal mortality and morbidity disproportionately affected sub-Saharan Africa, a comprehensive data on GBS are limited in the region. Therefore, we performed a systematic review and meta-analysis that aimed to estimate the prevalence of maternal colonization, vertical transmission, serotype distribution and antimicrobial resistance pattern of GBS isolates in sub-Saharan Africa. Methods: This systematic review was done according to Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines. MEDLINE/PubMed, CINAHL (EBSCO), Embase, SCOPUS, Web of Sciences databases, and Google Scholar were used to retrieve both published and unpublished articles. Two independent reviewers (FW and MTB) screened titles and abstracts and double-checked by a third reviewer (EH). The authors used STATA software version 17 for analysis of the selected articles. Forest plots using the random- effect model were used to present the findings. The heterogeneity was assessed using Cochrane chi-square (I²) statistics, while Egger intercept was used to assess publication bias.

Results: This systematic review and meta-analysis included 58 studies that fulfilled the eligibility criteria. The pooled prevalence of maternal RVC and vertical transmission of GBS were 16.06 [95% CI (13.94-18.30)] and 43.31% (95% CI: 30.75-56.32) respectively. The highest pooled proportion of antibiotic resistance to GBS was observed in Gentamycin, i.e., 45.58 (4.12-91.23), followed by Erythromycin, i.e., 25.11 (16.70-34.49). Nonetheless, the lowest antibiotics resistance was observed in Vancomycin, i.e., 3.84 (0.48- 9.22). Our finding indicate that serotypes (Ia/Ib/II/ III/V) cover almost 88.6% of serotypes in sub-Saharan Africa. Conclusions: The estimated high prevalence and resistance to different antibiotic classes observed in GBS isolates from sub-Saharan Africa suggest the need for implementation of effective interventions efforts. Further research on GBS should prioritize high-quality data, antibiotic resistance, sequence type and serotype distributions; these could help to guide the interventions efforts.

Digital intervention on the knowledge regarding anti-microbial resistance amongst the school-going adolescents: a non-randomized controlled study

Sweetey Jha¹, Arista Lahiri^{2,3}, Arista Lahiri⁴, Madhumita Dobe⁵

¹Dr BC Roy Multi Speciality Medical Research Centre, Indian Institute of Technology Kharagpur, Kharagpur, India, ²Indian Institute of Technology Kharagpur, India, ³Dr. B. C. Roy Multi-Speciality Medical Research Centre, India, ⁴Medical Research Centre, Indian Institute of Technology Kharagpur,

Kharagpur, India, ⁵Foundation for Actions and Innovations Towards Health Promotion, Bidhannagar, India

Background and Objective: Emerging and crucial public health issues like Anti-microbial resistance (AMR) need special attention amongst the general population, especially adolescents since it is not typically a part of the school curriculum but is essential for a healthier society. The current study aimed to determine the effectiveness of an online module-based intervention package in improving the knowledge regarding AMR among school-going adolescents. Methods: A non-randomized controlled interventional study was conducted among school-going adolescents aged 15–18 years (standard 9th–12th). In the intervention and control groups, 429 and 428 students were recruited, respectively. An online module-based intervention package comprising a booklet and interactive lectures to improve knowledge of anti-microbial resistance was implemented. A pre-tested and validated questionnaire containing ten multiple-choice questions with a single correct answer (maximum total score of 10) was used in the baseline and the follow-up survey. Generalized linear models assessed the effectiveness of the intervention considering the baseline and the follow-up observations.

Results: The mean age of the intervention and control groups were 15.52 (±1.25) years and 15.51 (±1.18) years, respectively, and 72.20% and 68.53%, respectively, were females. Following the intervention, the participants in the intervention group had a statistically significant improvement in their knowledge regarding AMR. Adjusting for the effects of age, gender, and baseline knowledge, the intervention group had a relative risk (95% confidence interval) of 1.13 (1.09 – 1.18) for scoring at least 5 and 1.26 (1.24 – 1.28) for unit improvement in score in the post-intervention assessment.

Conclusions: School-going adolescents are often the gateway to enlightening society with new knowledge and healthy habits. After the intervention, there was an improvement in the knowledge of the intervention group. Designing an effective school-based intervention package regarding AMR is essential. Intervention at an early age in this regard is critical to building a healthier society.

Attitudes towards use of high-importance Antimicrobials-a cross-sectional study of Australian veterinarians

Anna Sri¹, Kirsten Bailey¹, James Gilkerson², Glenn Browning¹, Laura Hardefeldt¹

¹Asia-Pacific Centre for Animal Health, University of Melbourne, Australia, ²Asia-Pacific Centre for Animal Health, University of Melbourne, Melbourne, Australia

The timely implementation of antimicrobial stewardship interventions could delay or prevent the development of higher levels of antimicrobial resistance in the future. In food-producing animals in Australia, high-importance antimicrobials, as rated by the Australian Strategic and Technical Advisory Group (ASTAG), include virginiamycin and third-generation cephalosporins (in individual pigs or cattle). The use of high-importance antimicrobials in companion animals is more widespread and less regulated. There is also potential for more rapid improvement in prescribing and guideline compliance in these areas of practice because much of the current use of high-importance antimicrobials is not guideline compliant and other treatment options are readily available. These sectors have also not traditionally been the focus of significant educational, public or regulatory pressures to reduce unnecessary antimicrobial use. There is no national antimicrobial use surveillance system for animals in Australia. Consequently, there is a gap in the knowledge about reasonable use across all sectors of veterinary practice. This study explored attitudes towards the use in veterinary medicine of antimicrobials with high importance to human health, and determined levels of agreement about the Introduction of restrictions or other conditions on this use. An online survey was distributed via social media and email from June to December 2020 to veterinarians working in Australia. Of the 278 respondents working in clinical practice, 49% had heard of the ASTAG rating system, and 22% used a traffic light system for antimicrobial importance in their practice. Overall, 61% of participants disagreed that veterinarians should be able to prescribe high-importance antimicrobials without restrictions. If there were to be restrictions, there was most agreement amongst all respondents for only restricting high-importance antimicrobials (73%). There is a need for education, guidance, and practical support for veterinarians for prescribing high-importance antimicrobials alongside any restrictions.

Infection control in the intensive care unit: the Pavia experience

Alice Sguelgia¹, Margherita Zeduri¹, Daniela Girardi¹, Marina Lanave²,

Rebecca Galvi², Alba Muzzi², Anna Odone¹

¹Department of Public Health, Università degli Studi di Pavia, Pavia, Italy,

²Medical Direction, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Health care activities could contribute to the spread of infections when standard precautions are not respected, as the COVID-19 pandemic showed. Every year in Italy 7% of patients contracts a healthcare-associated infection (HAI). HAIs are responsible for more than 10,000 deaths per year, and wards with fragile patients are the most affected. This study Aims to highlight the key role of prevention and control of HAIs, especially in critical units. In April 2022, an outbreak of *Acinetobacter baumannii* and Carbapenem-resistant *Klebsiella pneumoniae* occurred within the intensive care unit of IRCCS Fondazione Policlinico San Matteo, Pavia (Italy), affecting 9 patients. To address the issue, Medical Direction (MD) developed a strategy based on the specific biological characteristics of survival of the micro-organisms. The initiative resulted in daily monitoring of cases, observation of adherence to good hand hygiene practices by health professionals (HPs) and performance of rectal screening swabs to all patients, both at the admission and on a bi-weekly basis. Furthermore, recurring microbiological sampling on bronchoscopes were implemented, with an operating instruction being formulated, to deal with the highly operator-dependent nature of their reprocessing. Regarding environmental hygiene, MD provided for the use of Gialcool 70% disinfectant and disposable cleaning material, while the entirety of the area involved was sanitized. Hospital Infection Committee also organized an audit to raise HPs' awareness and train them to comply with good care practices. Thanks to the swift response provided by MD, the outbreak ended on May 29th. Actions to control infection spread were punctually and effectively implemented. COVID-19 pandemic represented an opportunity to increase preparedness to critical events, as the Pavia experience demonstrated. Therefore, it is crucial not to underestimate standard precautions, and to keep operating instructions and training programs updated, to provide high-quality care in an increasingly resilient health system, strengthened by the pandemic experience.

Coverage of policies to reduce Antimicrobial resistance in Low and Middle income countries: results from the first Global Expert Survey on Antimicrobial Resistance (GESAR)

Kyaw Ya^{1,2}

¹Swiss Tropical and Public Health Institute, Allschwil, Switzerland,

²University of Basel, Switzerland

Background: Antimicrobial resistance (AMR) constitutes a major threat to global health security. Overuse of antimicrobials is particularly common in low and middle-income countries (LMICs); however, little is known regarding the extent to which this is due to lacking national efforts to enforce rational antibiotic use in these settings.

Methods: To assess the current coverage of policies and interventions reducing the risk of AMR, we invited public health experts from all 138 current LMICs to participate in an online survey. Key coverage measures were compared to those collected in the 2021 Tripartite AMR Country Self-assessment Survey (TrACSS).

Results: A total of 352 completed surveys from 118 LMICs were analysed. Out of these 118 LMICs, 67% had a national action plan on AMR, 64% had legislative policies on antibiotic use, 58% had national training programs for health professionals, and 10% had a national monitoring system for antimicrobials. 51% of LMICs had specific targeted policies to limit the sale and use of protected or reserved antibiotics and 64% had policies to reduce the over-prescription of antibiotics by health workers. Even though 72% LMICs had prescription requirements, getting antibiotics without a prescription was reported to be possible in practice in 74% of LMICs.

Discussion: The Results presented here suggest that there are major gaps in the implementation and enforcement of policies to reduce the risk of AMR in many LMICs. Improved monitoring of national efforts particularly in the areas of enforcement, as well as improved monitoring of antibiotic use are urgently needed.

Conclusions: Legislative policies to restrict the sale and use of antimicrobials appear to be lacking in many LMICs today. Stricter enforcement of existing policies as well as improved surveillance of actual use are likely key to controlling antimicrobials use in LMICs settings. **Keywords:** Antimicrobial resistance, antibiotics, policies, low and middle-income countries

The acute toxicity, antimicrobial and anti-inflammatory profile of the ethanolic and acetone extract of the leaves *Teclea nobilis*

Hiwotemedhin Tegegne¹

¹Addis Ababa University, Addis Ababa, Ethiopia

Teclea nobilis, is a medicinal plant which is believed to have anti-inflammatory and antipyretic properties. In this study, the acute toxicity, the antimicrobial, and the anti-inflammatory profile of the plant are reported. One group served as a control and the other three groups received the different concentrations of the plant extract. 2000mg/kg, 1500mg/kg and 1000mg/kg were used. Weight, % PCV and liver biopsy were done at the end of the study to determine toxicity. All the mice showed increased weight throughout the study period. The % PCV measured at the start and end of the study showed decreased values from the time of the start of the study. The liver biopsy also showed some changes consistent with acute toxicity. For this reason, we recommend caution be taken in use of the plant especially in susceptible population. *Staphylococcus Epidermidis*, *Enterococcus Faecalis*, *Salmonella Typhi* and *Listeria Monocytogenes* were used as test bacteria for the antimicrobial study. Varying doses of the plant extract were used for the test which are 500mg/ml, 450mg/ml and 300mg/ml. The results shows the ethanolic/acetone plant extract has no antibacterial activity towards *S. Epidermidis*, *E. Faecalis* and *L. Monocytogenes*. Nevertheless, it was determined that it has moderate activities toward *S. Typhi*. And we recommend larger scale study be done to determine dosage and associated side effects with the plant. The anti-inflammatory testing was done on 30 mice which were divided in five groups. One group served as the control and received Normal Saline (NS) while the other three groups received different and increasing doses of the plant extract (600mg/kg, 400mg/kg and 200mg/kg) and the last group served as a negative control and only received NS. It was concluded the plant has some anti-inflammatory activity on higher doses. Based on this study we have recommended a largescale study be done.

Popul. Med. 2023;5(Supplement):A105

DOI: 10.18332/popmed/165353

Prescription pattern of antibiotics amongst dentists of Karachi, Pakistan

Juzer Shaikh¹, Muhammed Hydrie²

¹Karachi, Pakistan, ²Pakistan

Background: In dentistry, antibiotics are recommended for preventative and therapeutic purposes. Most baseless prescriptions of antibiotics have been reported in cases of ear and dental infections. Antibiotic resistance in children and adults may results from erroneous antimicrobials usage by clinicians, which is a critical global health hazard. The development of strict prescription guidelines and educational policies is urgently required. **Objectives:** The study's purpose was to observe whether the dental practitioners are following the established global standards or not and to examine the antibiotics prescription pattern among dentists.

Methods: A cross sectional study consisted of 401 participants conducted in government institutes and private teaching institutions of Karachi, Pakistan. The individuals have been questioned by a validated survey form that contains descriptive information and examples of different therapeutic Findings, after obtaining authorized approval, verifying the eligibility standards. SPSS 20 was used to enter and evaluate the data. Chi square test was used for inferential analysis.

Results: Participants mean lifespan was 31 ±5.6 years, and 57.6% (n=231) of them were women. The majority of them, or 76.3% (n=306), evaluated to treat 15 or less kids every month, whereas 23.7% dentists (n=95) handled more than 15 kids in a month. Additionally, 82.8% (n=332) of the dentists worked at hospital dentistry, while 44.4% (n=178) saw patients in the public sectors outpatient department. The overall compliance with professional recommendations ranged from 38.6% to 75.6%. **Conclusions:** This study demonstrates that most dental professionals do not follow professional recommendations for prescribing antibiotics to treat pediatric oral infections. The pattern of antibiotic prescription by dentists appears to conflict with the advised professional guidelines. The majority of dental professionals (63.8%) prescribed antibiotics, with female dentists being more likely (57.6%) to follow professional antibiotic standards. Dental practitioners need regular updates and continuing medical education on the subject to adhere with guidelines.

Antibiotic residues of drinking-water and its human exposure risk assessment in rural Eastern China

Yingying Wang¹, Chaowei Fu¹, Na Wang¹, Fei Yan¹, Qingwu Jiang¹

¹Fudan University, China

Background and Objective: Trace levels of antibiotics were frequently found in

drinking-water, leading a growing concern that drinking-water is an important exposure source to antibiotics in humans. This study was aimed to investigate the occurrence and seasonal variation of twenty-seven antibiotics in tap water and well water in the rural residential areas in Eastern China, and to assess the related human health exposure risks in drinking-water.

Methods: A total of 278 tap water samples and 110 well samples were collected for seven consecutive days in August 2020 (Summer) and January 2021 (Winter). Twenty-seven antibiotics were analyzed by ultra performance liquid chromatography-tandem mass spectrometry. The average daily dose (ADD) and the health risk quotient (HRQ) for exposure to detected antibiotics in humans were evaluated using 10000 times of Monte Carlo simulations, based on the parameters from local residents randomly selected from the population cohort previously established in two rural areas of Eastern China.

Results: Of 27 selected antibiotics, ten were detected in the drinking-water samples, including five macrolides, three sulfonamides, one phenicols and one fluoroquinolones. Azithromycin showed the highest detection frequencies (79.71-100%), followed by roxithromycin (25.71-100%) and erythromycin (21.43-86.96%). The highest detection concentration of > 2 ng/L was seen for 9 out of 10 detected antibiotics, with the maximum concentration reaching 6.59 ng/L for tilmicosin. Noticeable seasonality was observed for macrolides, sulfonamides and phenicols. The estimated ADD and HRQ for human exposure to a mixture of antibiotic residues through drinking-water was less than 0.01 g/kg/day and 0.01, respectively, which varied over sites, water types, seasons and sex. Macrolides accounted for 46% to 67% of the total HRQs.

Conclusions: Antibiotic residues of drinking-water were common with the seasonality, and brought acceptable health risks, in rural Eastern China, while the long-term exposure patterns to low-dose antibiotics from drinking-water should not be ignored.

Popul. Med. 2023;5(Supplement):A107

Has *Mycobacterium chimaera* become a public health concern? A bibliometric analysis

Alessia Martinelli¹, Giuseppina Moro¹, Paolo Ragusa¹, Valerio Brescia², Giacomo Scaioni^{3,4}, Davide Minniti^{1,4}, Fabrizio Bert^{1,4}, Roberta Siliquini^{1,5}

¹Department of Public Health Sciences, University of Turin, Italy,

²Department of Management, University of Turin, Italy, ³Department of Public Health Sciences, University of Turin, Italy, ⁴Health Local Unit ASL TO3, Turin, Italy, ⁵AOU City of Health and Science of Turin, Italy

Background and Objective: *Mycobacterium chimaera* (*M. chimaera*), a slow-growing non-tuberculous member of the *Mycobacterium avium* complex (MAC), was identified as a new species in 2004. Recently, *M. chimaera* has been in the spotlight as a cause of disseminated infection in patients following cardiac surgery performed with contaminated heater-cooler units (HCUs). *M. chimaera* infection has a long lasting latency: many years pass from infection to disease onset. *M. chimaera* is resistant to antimicrobial agents and its infection has high lethality. Thus, the aim of this study is to assess publication and citation related metrics, identify Keywords and most frequently discussed topics, and appraise geographic distribution of published articles. **Methods:** On date 2022/11/15 a directory of all publications containing "*Mycobacterium chimaera*" OR "*M. chimaera*" in all fields was excerpt from Web of Science. Bibliometric analysis was carried out using bibliometrix and biblioshiny packages on RStudio.

Results: Total publications were 305 with an annual growth rate of 20.09% from 2004 to 2022. In 2017, a total of 53 articles were produced. Total citations were 4258, with an average of 14.43 citations per document. The most cited paper was about an outbreak after open-chest heart surgery. Only 2.45% of 1475 authors wrote >4 papers about *M. chimaera*, according to Lotka's law. The US and Switzerland were the countries with the largest production, followed by the UK, Germany and Italy. The three most frequent words were "cardiac-surgery", "outbreak", and "valve". Before 2016, Keywords related to cardiac-surgery, heater-cooler units and outbreaks were totally absent. The most relevant sources were "Journal of Hospital Infection" and "Clinical Infectious Diseases". **Conclusions:** Our study sheds light on *M. chimaera* as a pathogen involved in a worldwide alert due to high number of cardiothoracic surgical procedures requiring HCUs. It would be advisable to plan interventions to reduce its burden.

An innovative sanification system in the Operating Theatre with a focus on sustainability

Francesco Caro¹, Giuseppina Moccia², Francesco Caro^{3,2}, Oriana Motta², Ornella Piazza², Antonella Maisto², Giovanni Boccia², Mario Capunzo², Walter

Longanella², Emilia Vozzela²

¹Dipartimento di Medicina, Chirurgia e Odontoiatria Scuola Medica Salernitana, Università di Salerno and AOU San Giovanni di Dio e Ruggi d'Aragona, Italy, ²AOU "San Giovanni di Dio e Ruggi d'Aragona", Italy,

³Università di Salerno, Italy

Background and Objective: Protecting and promoting public health at a national and global level is a challenge of the medical and scientific societies, that work together in their respective and multidisciplinary fields to promote a healthy world and build a more sustainable future. To guarantee an effective reduced contamination of the Operating Theatre and reduce the environmental impact, the Salerno University- School of Medicine has founded the Green Operating Theatre group, to work together to reduce the footprint of the perioperative environment and enhance the sanification performance of the healthcare system.

Methods: Our group has developed a Green Operating Theatre agenda to follow along on the sustainability journey, aimed at implementing: innovative sanification procedures, waste reduction, anesthesia gas management and energy use improvement. Our first action was to reduce mishandled noninfectious waste in OR, in particular the use of disposable shoes covers, for patients and health care workers, since they not only produce non-recyclable waste but are not sufficiently effective at reducing contamination.

Results: We implemented the use of a shoes sanitizing station, a system which, through ozone gas and UV light, sterilizes health personnels' shoes at each OR access. This particular system not only guarantee an effective reduced contamination of the Operating Theatre but leads to lower environmental burden with the management of noninfectious waste, thus combining clinical needs and sustainability considerations.

Conclusions: This approach is aimed at increasing the level of sanitation of the operating theatres and the healthcare settings, underling a renewed interest in environmentally sound and sustainable sanification practice.

Development and sustainability of a digital auditing program to support national antimicrobial surveillance

Steve Christov¹, Caroline Chen², Ron Cheah², Noleen Bennett³, Karin Thursky², Lisa Hall², Courtney Ierano², Rodney James²

¹Melbourne Health - Guidance Group, Australia, ²Melbourne Health- Guidance Group, Australia, ³Melbourne Health Guidance Group, Australia

Background and Objectives: The National Antimicrobial Prescribing Survey (NAPS) is a novel digital antimicrobial auditing program. The Hospital NAPS, released in 2013, is used to monitor antimicrobials prescribed within a facility and identify targets for quality improvement initiatives. Since 2016, the Hospital NAPS has also become a key component of the Antimicrobial Use and Resistance in Australia (AURA) Surveillance System, providing actionable data at a local and national level to address the challenges of antimicrobial resistance.

Methods: The Hospital NAPS uses a standardised point prevalence Methodology and assessment matrix to facilitate data collection on the appropriateness of antimicrobial prescribing and allow benchmarking. Deidentified data is then made available for national reporting and to inform antimicrobial prescribing guidelines and public health policy. Establishment of governance processes under a quality management system framework and ongoing feasibility assessments, have driven improvements in the program's generalisability and sustainability.

Results: Since released, over seventy percent of Australian hospitals have contributed across major cities, regional and remote settings. It can now be regarded as a national antimicrobial usage surveillance system with 407 hospitals contributing in 2021. Key findings have informed updates to national prescribing guidelines including respiratory tract infections, surgical prophylaxis and medication safety. The ongoing success of the Hospital NAPS program has driven the development of additional modules, including Surgical, Aged Care, Quality Improvement and Antifungal NAPS.

Conclusions: The adaptability of Hospital NAPS has enabled successful pilots in New Zealand, Canada, United Kingdom, Portugal, Malaysia, Vietnam, Bhutan, Nepal, Papua New Guinea, Timor-Leste and Fiji, highlighting its across transferability various geographical locations and settings. Acceptable governance structures, along with robust in-built analysis and reporting capabilities, has supported such sustainability and scalability, ensuring broader impact globally to help address antimicrobial resistance.

Impact of new Electronic Health Record on antimicrobial stewardship policies in IRCCS Policlinico San Donato

Demetrio Cescutti¹, Margherita Zeduri², Carlo Lunetti¹, Alessandro Meloni², Aurelia D'Acquisto³, Laurenzia Ferraris⁴, Giuseppe Caravella⁵, Maria Shishova⁵, Giulia Bisinella⁵, Luca Carpinelli³, Anna Odone⁶, Carlo Signorelli¹, Maria Cuppone³

¹Facoltà di Medicina e Chirurgia, Università Vita-Salute San Raffaele, Italy, ²Dipartimento di Sanità Pubblica, Medicina Sperimentale e Forense, Università degli Studi di Pavia, Italy, ³Direzione Sanitaria, IRCCS Policlinico San Donato, Italy, ⁴IRCCS Policlinico San Donato, Italy, ⁵UO Farmacia, IRCCS Policlinico San Donato, Italy, ⁶Dipartimento di Sanità Pubblica, Medicina sperimentale e forense, Università degli Studi di Pavia, Italy

Background: Appropriate antibiotic prescription is crucial to antimicrobial stewardship, supporting antimicrobial resistance reduction. In Irccs Policlinico San Donato, Milan (Italy), at the start of 2022 a motivated request form for the prescription of several antibiotic and antifungal medications was introduced. Furthermore, Electronic Health Record (EHR) for the management of pharmacotherapies was implemented in several departments of polyclinic in July 2022, allowing a direct monitoring of prescriptions by the pharmacists, which was not possible before. The aim of this study is therefore to evidence the importance of EHR for the direct monitoring of requests, evaluating also the economic loss resulting from the inappropriate prescriptions.

Methods: Overall, 55 motivated requests for meropenem, daptomycin and caspofungin sent during September and October to the pharmacists were reviewed. We compared the delivered doses with the relative administrations through the EHR for each patient. We also estimated the economic loss resulting from the doses delivered but not administered.

Results: There were 17 motivated requests for meropenem, 7 of which involved 70000 milligrams (mg) of delivered doses but not administered; 157000mg were administered without a corresponding motivated request. Regarding daptomycin, out of 30 requests, 13 involved 26660mg of delivered doses in excess while 37400mg were administered without a request. Out of 8 caspofungin requests, 4 involved 900mg of delivered doses in excess and 2090mg were administered without a request. Overall, €2016 were lost due to the excess delivered doses. **Conclusions:** The introduction of the EHR allowed a direct monitoring of motivated requests appropriateness; this is the first step to manage the inappropriate pharmacological prescriptions. Next step should be to integrate the motivated request form in the software, during the prescription of the medications that require it. This would prevent doctors from submitting wrong or incomplete requests, therefore strengthening antimicrobial stewardship and improving the appropriateness of their usage.

DOI: 10.18332/popmed/165698

Wastewater treatment plant: a hotspot of antibiotic resistance spreading?

Manuela Macri¹, Manuela Macri¹, Sara Bonetta², Marta Catozzo¹, Cristina Pignata², Enrica Mecarelli³, Valentina Schiavo³, Claudio Medana³, Elisabetta Carraro², Silvia Bonetta¹

¹Department of Life Sciences and Systems Biology, University of Turin, Turin, Italy, ²Department of Public Health and Pediatrics, University of Turin, Turin, Italy, ³Department of Molecular Biotechnology and Health Sciences, University of Turin, Turin, Italy

Background and Objective: Antibiotic resistance (ABR) is of primary concern for Public Health. As reported by the European One Health Action Plan against Antimicrobial Resistance, there is the need to monitor the presence of antibiotics, antibiotic resistant bacteria (ARB) and antibiotic resistance genes (ARGs) in the environment, especially in wastewater. Moreover, the global action plan on antimicrobial resistance underlines the need to obtain strong evidence associated to the role of wastewater and environment as contributors to the development and spread of ABR. The aim of this study is to evaluate the ABR spreading in different treatment steps of wastewater treatment plant (WWTP) also considering the possible reuse of effluent in agriculture.

Methods: Samples collected at different steps of a WWTP developed for reuse were investigated for the presence of antibiotics (ampicillin, tetracycline, sulfamethoxazole), heavy metals, the antibiotic resistance rate of ARB (ampicillin, tetracycline, and sulfamethoxazole resistant bacteria) and ARGs (blaTEM, tetA, sulII).

Results: The Results obtained highlight the presence of ARB and ARGs for the antibiotics tested in WWTP, with a decreasing trend during the wastewater treatment, as also observed for some antibiotics and heavy metals. Although there is generally no significant difference in the ABR rate, a higher average value of this rate is observed during the wastewater production, suggesting a possible positive selective pressure of ARB by some steps of treatment. A correlation was

also observed between the presence of some heavy metals and ABR rate.

Conclusions: The results obtained suggest the need to carefully monitor the role of WWTPs in the spreading of antibiotic resistance, also considering the One Health approach. Furthermore, the results obtained could suggest interventions to reduce the human health risk associated with wastewater reuse in agriculture.

Antibiotic stewardship: perception of general practitioners regarding emerging challenges

Tabinda Ashfaq¹, Aisha Ishaque²

¹Iqra University faculty of health sciences 501-B Sea breeze Center boat basin block 5 Clifton Karachi Pakistan, ²Indus hospital Karachi, Pakistan

Introduction: Antibiotics are among the most frequently prescribed classes of drugs all over the world with approximately 50% of it being used without any rationale. This leads to increase antibiotic resistance and further complications. General practitioners are first line of contact and majority of the general population presents to them for their health issues. Their perception and attitude regarding antibiotic prescription plays an important role in emerging antibiotic resistance. **Objective:** To identify knowledge and perception of General practitioners regarding antibiotic stewardship and associated challenges.

Methodology: This is a cross sectional study conducted through online platform conducted through a pretested self-administered questionnaire. It included questions related to location and workplace information. Knowledge and practices of the participants regarding antibiotic use in their clinical practice and experience of health care workers related to patient exposure and protective equipment. Data was entered and analyzed using the SPSS statistical software Version 19.

Results: A total of 270 out of 373 agreed to participate in the study with a response rate of 72%. On exploring relevance of importance of antibiotic resistance in daily work majority 81% agreed that it is highly relevant. Similarly when asked about reasons for increasing antibiotic irrational use of antibiotics was a major reason identified by 96% of male and 84% of females.

To explore GPs practice regarding education to patients around 66% of male and 85% of the females agreed that they educate their patients when prescribing while 35% male and 15% female physicians did not educate their patients because of lack of time available for patient education during consultation.

Conclusion: Antibiotic resistance is on the rise. General practitioners have limited knowledge regarding rationale use however their practice is limited due to poor accountability, increase demand from patients and to enhance their patient satisfaction

Chondrodendron platyphyllum alkaloids as a weapon in the combat of antibiotic resistance

Jaime Ribeiro Filho¹, Silvio Caetano Alves Júnior¹, Maria Costa², Ray Silva de Almeida², Ana Pereira da Silva², Irwin Rose Alencar de Menezes², Henrique Douglas Melo Coutinho²

¹Oswaldo Cruz Foundation, Fiocruz Ceará, Eusébio, Ceará, Brazil, ²Regional University of Cariri, Brazil

Background and Objective: Antibiotic resistance is a significant public health problem, contributing to approximately 700,000 deaths yearly worldwide. Due to the rapid spread of multidrug-resistant bacteria (MDR), the arsenal of effective antibiotics has decreased, demanding the urgent development of new drugs. Evidence has indicated that Chondrodendron platyphyllum (Menispermaceae) is a source of compounds with antimicrobial properties. Thus, the present study aimed to investigate the effects of its alkaloids on antibiotic resistance in vitro. **Methods:** A Total Alkaloid Fraction (TAF) and the primary constituent curine were obtained from the root bark of C. platyphyllum (SisGen registry A84A87E). The antibacterial and antibiotic-enhancing activity of TAF and curine was evaluated by determining their minimum inhibitory concentration (MIC) individually or in combination with antibiotics against standard and MDR strains of Staphylococcus aureus, Pseudomonas aeruginosa, and Escherichia coli.

Results: The TAF presented clinically effective MICs against S. aureus 25923 (645 µg/mL), P. aeruginosa 9027 (645 µg/mL), and E. coli 25922 (256 µg/mL) but failed to effectively inhibit the growth of the MDR strains S. aureus 10, P. aeruginosa 24, and E. coli 06 (MIC ≥ 1,024 µg/mL). On the other hand, curine showed promising antibacterial effects against S. aureus 25923 (512 µg/mL), E. coli 25922 (512 µg/mL), and E. coli 06 (813 µg/mL). Regarding the effects on antibiotic resistance, TAF potentiated (p < 0,05) the activity of gentamicin and norfloxacin against MDR strains of S. aureus, P. aeruginosa, and E. coli. On the other hand, curine

potentiated the activity of gentamicin against the gram-negative MDR strains and presented synergism when associated with norfloxacin against *S. aureus* 10 and *P. aeruginosa* 24.

Conclusion: *C. platyphyllum* and curine have antibacterial and antibiotic-enhancing activities against the standard and MDR bacterial strains and, as such, have the potential to be used in the combat of antibiotic resistance.

Developing the monitoring and evaluation framework for 'Australia's antimicrobial resistance strategy: 2020 and beyond' using a one health approach

Lisa Hall¹, Sheleigh Lawler¹, Tracy Comans², Simon Reid¹, Ricardo Soares Magalhães³, Mark Blaskovich⁴, Julia Henseleit², Alyssa Welch²

¹University of Queensland, School of Public Health, Australia, ²University of Queensland, Centre for Health Services Research, Australia, ³University of Queensland, Queensland Alliance for One Health Sciences, Australia, ⁴University of Queensland, Institute for Molecular Bioscience, Australia

Background and Objective: Antimicrobial Resistance (AMR) is a growing global concern inextricably linked to human interactions across multiple sectors, including animal health, agriculture, food production, and the environment. Using a One Health lens, to understand the spread and risk of AMR, will be vital to successfully addressing such a complex issue. International efforts are focussed on designing and implementing policy – but developing and implementing comprehensive monitoring and evaluation frameworks for national strategies remains a challenge. Working with a broad range of stakeholders, we aimed to co-design a pragmatic, adaptable monitoring and evaluation (M&E) framework for Australia's AMR Strategy.

Methods: To develop the M&E framework we employed multi-stage, iterative co-design. We undertook a scoping review and interviews with international leaders involved in monitoring national AMR strategies to examine best practice, enablers and barriers. We then engaged an Expert Advisory Group (EAG) with diverse One Health expertise. We undertook a policy analysis of national strategy documents and worked with our EAG to draft program logic models (PLMs) – using backcasting to formulate the inputs, outputs and outcomes required to address AMR. We conducted Delphi surveys (n=15 experts/sector), to get consensus on the importance and feasibility of outcome measures. In early 2023 we will explore the Delphi findings and refine the PLMs in national systems thinking workshops - prioritising what needs to happen next for M&E to be successfully implemented. Workshops will focus on identifying linkages and leverage opportunities between and within sectors.

Results: This co-design approach (using established public health methods) is providing Australia with a systematic, collaborative, and responsive way to create an M&E framework across multiple One Health sectors.

Conclusion: Evaluating the impact of national AMR strategies is complex, takes time, and needs to champion the voices of a range of stakeholders. Systems thinking is useful for facilitating this.

Predictors of knowledge, attitude, and dispensing practices of antibiotics among patent and proprietary medicine vendors in Federal Capital Territory, Nigeria

Abara Erim¹, Yakubu Abdullahi¹

¹Nigeria Centre for Disease Control, 24 Amino Street, Galadimawa, Abuja, Nigeria

Background and Objective: Patent and Proprietary Medicine Vendors (PPMVs) are seen as the most reliable sources of healthcare in most rural and hard-to-reach areas even with their low educational qualification. They can sell a limited number of pre-packaged, over-the-counter medicines and medical products, but are prohibited from selling prescription medications including antibiotics. However, studies have shown that people get antibiotics without prescription from patent medicine vendors resulting in irrational antibiotic use in some cases. This study, therefore, assessed the predictors of knowledge, attitude, and dispensing practices of antibiotics among patent and proprietary medicine vendors in the Federal Capital Territory, Nigeria.

Methods: A descriptive cross-sectional study design was employed, and 374 respondents were selected using a multistage sampling technique. A standardized, structured, interviewer-administered questionnaire was used among PPMVs. Statistical Package for Social Sciences (SPSS) version 22.0 was used for data analysis. Chi-square was used for test of association at p0.05.

Results: The majority (53.4%) of PPMVs were females; about four-fifth belonged to

the age group 29 years, and a majority had about 5 years of practice experience. The majority (66.0%) of the respondents had poor knowledge of antibiotics, and almost half (59.2%) of the PPMVs had poor dispensing practices of antibiotics. Sex, educational level, and membership of PPM were found to be predictors of knowledge, while sex and educational level were predictors of dispensing practices of antibiotics among PPMVs. Also, it was found that the majority of the PPMVs had good attitude toward antibiotics prescription.

Conclusion: This study reported a poor overall knowledge and dispensing practice of antibiotics among PPMVs and good attitude towards antibiotics prescription. In order to curb the menace of irrational antibiotic use, strict enforcement of regulations that will limit access to antibiotics by PPMVs and continuous training of the PPMVs on antibiotic use is required.

Evaluation of the available apps to support the Italian physicians in the Antimicrobial Stewardship implementation

Giuseppa Russo¹, Annachiara Petrazzuolo¹, Marino Trivisani¹, Giuseppe Virone¹, Luca Arnoldo², Roberto Cocconi³, Laura Brunelli⁴

¹University of Udine, Department of Medical Area - University of Udine, Udine, Italy, ²University of Udine, ³Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy, Accreditation and Quality Unit, Friuli Centrale Healthcare University Trust, Udine, Italy, ⁴University of Udine, "Department of Medical Area - University of Udine, Udine, Italy and Accreditation and Quality Unit, Friuli Centrale Healthcare University Trust, Udine, Italy

Background and Objective: Antimicrobial resistance (AMR) is a serious problem and remains one of the greatest global threats to public health at the beginning of the 21st century. As digital technologies become an important resource for healthcare delivery and public health, we decided to investigate the available apps to support Italian physicians combat AMR.

Methods: A systematic research was performed by four independent researchers in the Apple and Google Play App stores using English and Italian keywords. After excluding content in languages other than Italian or English, gaming, photo and video, paid apps and contents, and advertisement, apps were downloaded and analysed using an 86-item checklist including pathogens/etiological agents, support for diagnosis and therapy, AMR, dashboard function, antimicrobial stewardship (AMS), notes and recordings, network, technical characteristics of app domains as validated by experts.

Results: Of the 115 apps initially identified, 27 (6 for Android, 21 for iOS, 1 for both) were analyzed. No app met all desirable aspects; only one met 36% of the criteria. From highest to lowest scores, domains are support for diagnosis and therapy (37%), technical characteristics of the app (22%), AMS (8%), pathogens/etiological agents (4%), notes and recordings (3%), network (2%), AMR (1%) and dashboard function (1%). Most apps support identification of the drug for targeted therapy against a specific microorganism (78%) and the ability to be used offline (81%).

Conclusions: No available app was able to adequately provide the desired features. To engage all prescribing physicians in the fight against AMR and implement AMS, an app that meets all requirements must be developed.

Malnutrition and extended spectrum beta-lactamase-producing Enterobacteriaceae infection: a new lead against antibiotic resistance?

Fabiana Cazzorla¹

¹Grenoble Alpes University Hospital and Grenoble Alpes University, France

Background and Objective: Infections with extended-spectrum beta-lactamase-producing Enterobacteriaceae (ESBL-E) are frequent in nursing home for dependent elderly people and several risk factors for ESBL-E infection are described in the literature. In patients hospitalized in nursing homes or healthcare facilities, malnutrition reaches 70%. The objective of this study was to analyse the relationship between malnutrition and ESBL-E infection.

Methods: A retrospective matched case-control study was carried out on adult patients hospitalized at Grenoble Alpes University Hospital between January 2010 and December 2015. Cases presented ESBL-E infection and controls had Enterobacteriaceae infection without ESBL resistance. The exposure factor, malnutrition, was based on national High Authority of Health (HAS) 2019 criteria adapted to French population. Patients without any measurement attesting the malnutrition were considered as not malnourished. The following ESBL-E infection risk factors were included: history of antibiotic prescription, history of hospitalization, risky procedures, history of ESBL-E colonization. The crude and

adjusted odds ratio (OR) and its 95% confidence interval (95% CI) were evaluated by conditional logistic regression.

Results: A total of 16,143 patients had at least one positive clinical sample for Enterobacteriaceae (1,364 ESBL and 14,779 no-ESBL). After matching, 1359 cases and 2663 controls were included in the analysis.

Malnutrition was a significant risk factor for ESBL-E infection in bivariate analysis (OR 1.24; 95% CI 1.08-1.43). By adjusting for risk factors, undernutrition was no longer a significant risk factor (adjusted OR 1.24; 95% CI 1.08-1.43). The usual risk factors: history of antibiotic prescription, history of hospitalization and history of ESBL-E colonization were significant in both analyses.

Conclusion: A significant relationship between undernutrition and the occurrence of ESBL-E infection was observed in bivariate analysis, but this factor is no longer significant when adjusting for other known risk factors. Further investigations, as subgroup analyses, could assess the importance of malnutrition as a risk factor.

⁴IRCCS Policlinico San Donato, ⁵IRCCS Policlinico San Donato U.O. Farmacia

Italy, ⁶IRCCS Policlinico San Donato Direzione Sanitaria Italy

Introduction: antimicrobial stewardship policies are crucial in the fight against hospital-acquired infections (hais) and antimicrobial resistances. A new stewardship program was introduced in irccs policlinico san donato in 2022, consisting in a motivated request form for antimicrobial intravenous medications. The aim of this study is to analyse the daily defined dose (ddd) for every intravenous antimicrobial during the last four years and estimate the pharmacoeconomic impact of the stewardship policies in our hospital.

Methods: The retrospective observation on antimicrobial consumption took place in the period january – october for the years 2019-2021 and a comparative analysis with 2022 was performed. The motivated request form was introduced for all the units and required as mandatory for prescription, along with an infectious disease counseling and microbiological tests. In the second half of 2022 the electronic health record was introduced in the hospital, enabling control on prescriptions. The total costs were calculated per operative unit linked to the requests of antimicrobials and ddd were calculated for each antimicrobial.

Results: Considering the ddd/100 days of hospital stay no reduction was observed in 2022 with 52,22 ddd/100d administered but concerning the prescription pattern we could observe during 2022 a significant drop in consumption of broad-spectrum antibiotics such as ceftriaxone or amoxicillin. A significant drop in total pharmaceutical expenditure was observed too, with a median reduction of 25% of total costs.

Conclusion: New stewardship policies not only led to more appropriate antibiotic usage in every unit but they led to a reduction in total pharmaceutical costs. The stricter controls on the antimicrobials requests led to a virtuous mechanism of more appropriate antimicrobial choice and length of treatment. In the long run this can result in a drop both in terms of direct costs (medications, nurse working-time) and indirect costs (shorter hospital stayings and less infectious complications).

Animals and animal products as sources for antimicrobial resistant bacterial infections in humans: a systematic review and meta-analysis.

Christina Fastl¹, Carlotta Di Bari², Brecht Devleeschauwer¹

¹Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium, ²Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium

Background and Objective: Antimicrobial resistance (AMR) is a major threat to modern medicine and expected to become one of the leading global health challenges of the century. Resistant infections in animals are known to be important drivers of AMR in humans, however, the extent of their contribution is not clear. To adequately assess the total economic and public health burden posed by animal diseases, as well as optimally inform effective AMR mitigation and control strategies, a better understanding of the relative impact of animal

AMR on humans is crucial. Source attribution studies are valuable tools for the partitioning of health burdens to specific sources and thus well suited for this purpose. The aim of this systematic literature review is to summarize the available evidence from source attribution studies and other studies that quantify the direct contribution of animal sources of AMR to resistant infections in humans, focusing on bacterial AMR.

Methods: Our initial search of four scientific databases (Pubmed, Web of Science, Scopus and Embase) yielded 16,955 results published between 1957 and 2022. Articles will be selected for eligibility based on whether they attribute bacterial AMR in humans to animal-related sources, which we defined as livestock, aquaculture, foods of animal origin and companion animals. We also intend to perform meta-analyses with the results of relevant studies of animal-related risk factors for sporadic resistant infections in humans to derive population attributable fractions.

Results and conclusion

We will provide an overview of the currently available evidence on the impact of zoonotic AMR on human health, outline important knowledge gaps and discuss suitable methods for future research.

The role of a Local Health Unit in fighting antimicrobial resistance: the experience of ASL TO3 in Piedmont, Italy

Alessandro Prinzivalli¹, Paolo Ragusa¹, Giulia Libero¹, Valerio Bordino¹, Grazia Ceravolo², Elvio Peyrone², Daniela Zeme², Davide Minniti², Roberta Siliquini³, Fabrizio Bert⁴

¹University of Turin Department of Public Health Sciences and Pediatrics Italy, ²Local Health Unit TO3 Local Health Unit TO3 Italy, ³University of Turin Department of Public Health Sciences and Pediatrics; A. O. U. City of Health and Science of Turin Italy, ⁴University of Turin Department of Public Health Sciences and Pediatrics; Local Health Unit TO3 Italy

Background and Objective: Antimicrobial Resistance (AMR) represents a global health threat which, as reported by recent analyses, could cause 10 million deaths/year by 2050. According to international guidelines, a dedicated Antimicrobial Stewardship (AMS) team was implemented in asl to3, a local health unit in piedmont, in order to process data and to improve good practices related to responsible antibiotic use. The aim of this study is to evaluate the Carbapenem-Resistant Enterobacteriaceae (CRE) 5-years trend in asl to3 as an indicator of ams strategies implemented.

Methods: CRE laboratory data were extracted through the virtuoso platform. redundancies were eliminated within 28 days, but any "duplicates" per material and any "multiple isolations" were retained. The analysis included stratification by pathogen, E. Coli (EC) and Klebsiella Pneumoniae (KP), and by presence or absence of resistance.

Results: AMS included strategies such as data collection and analysis about antibiotics prescriptions and microbiological tests, medical health records audit and meetings with clinicians. Despite a 9% increase in microbiological testing, an overall decrease in total and stratified cre from 2017 to 2021 was recorded. Total CRE dropped from 222/7368 (3.01%) to 136/8054 (1.68%), KP carbapenem-resistant from 18.86% to 11.74% and EC carbapenem-resistant from 0.71% to 0.09%. Almost all of the CRE bacteremia diagnosed in 2021 was caused by KP (95.6%), and only a small portion by EC (4.4%).

Conclusion: Since the implementation of an ams program, data related to cre infections has been continuously improving and are currently lower than regional and national trends. A decrease in antimicrobial-resistant microorganisms infections can result in reduced mortality and cost of care. A constructive comparison of the action of several health care settings in the field of ams can be a weapon in the global fight against amr.

The dual effect of governance quality on antibiotic use and antimicrobial resistance: An analysis of European countries

Antonella Agodi¹, Andrea Maugeri¹, Giuliana Favara¹, Roberta Magnano San Lio¹, Martina Barchitta¹

¹University of Catania Department GF Ingrassia Italy

Background and Objective: Although antibiotic use is one of the most important contributors to antimicrobial resistance (AMR), there is also evidence that their correlation is not always perfect. In fact, other factors (e.g., economic development and governance quality) may explain differences in AMR levels observed between countries. Here, we used ecological data to evaluate how governance indicators relate to antibiotic use and AMR in 30 European countries.

Methods: We used data from the World Bank Databank, ECDC atlas, and ESAC-Net databases to compile a dataset of six governance indicators (voice and accountability, political stability, government effectiveness, regulatory quality, rule of law, and control of corruption); AMR proportions for 25 combinations of pathogens and antibiotics; and the amount of antibiotics consumed in the community. AMR proportions and governance indicators were also aggregated into an overall measure of AMR and a governance index.

Results: Except for political stability, all governance indicators were inversely correlated with the proportions of: *Acinetobacter* spp. and *Pseudomonas aeruginosa* resistant to all classes of antibiotics under consideration; *Klebsiella pneumoniae* resistant to fluoroquinolones, third generation cephalosporins, and aminoglycosides; *Escherichia coli* resistant to fluoroquinolones and third generation cephalosporins; and *Staphylococcus aureus* resistant to methicillin (p -values<0.001). Linear regression analyses showed that an increase in the governance index resulted in significant decreases of overall antibiotic consumption (p <0.001) and AMR proportion (p =0.006). A mediation analysis showed that the governance index had an indirect effect on AMR via reducing antibiotic consumption, which accounted only for 35% of the total effect.

Conclusion: These findings supported the hypothesis that other factors sustain the uncontrolled spread of resistant pathogens in countries with poor governance. For this reason, reducing antibiotic use alone is unlikely to solve the AMR problem, and more interventions are needed to increase governance effectiveness at all levels.

The vaccinating hospital: Multiparametric evaluation of the post-vaccinal outcome on the development of infections, antibiotic therapy and resistance

Francesco Giordano¹, Cristina Genovese², Daniela Lo Giudice³, Sebastiano Calimeri³, Vincenza La Fauci², Raffaele Squeri⁴

¹Università degli Studi di Messina, Scuola di Specializzazione in Igiene e Medicina Preventiva Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina, Messina, Italy, ²Università degli Studi di Messina, ³Università degli Studi di Messina Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina, Messina, Italy, ⁴University of Messina Italy

Background: The moment of vaccination counseling also represents a very important tool in the hands of the healthcare operator because it gives the possibility to interact directly with the vaccinated person.

Our aim is the analysis of perception, attitudes, knowledge of antibiotics and antibiotic resistance in a cohort of chronic patients and the evaluation of the effect of vaccination counseling on these parameters.

Methods: A prospective study was conducted in the AOU "G. Martino" of Messina from 1 April 2022 to 1 October 2022, at the vaccination center of the Hospital Hygiene, after collection of informed consent and administration of the chosen vaccination. The study was carried out by completing a questionnaire created ad hoc by phone to evaluate knowledge, attitudes and perceptions of antibiotics as well as the role of vaccination counseling on the posthumous use of antibiotics and on the development of infections.

Results: 47 individuals joined the study, 44.68% male and 55.32% female. It was possible to highlight a satisfactory level of knowledge of antibiotics and the concept of antibiotic resistance, with a percentage of just over 80% of the participants who answered correctly to the questions formulated. 23.4% had never heard of antibiotic resistance and more than half of the sample did not know the correct definition.

The counseling carried out after the administration of the vaccine, approximately 47% of the sample used antibiotics, all of these followed the therapy indicated by the doctor and only one case was found to have antibiotic resistance.

Conclusion: From the data in our possession, it emerges that vaccination combined with adequate patient counseling by hospital vaccination center operators are activities of fundamental importance in order to reduce the inappropriate use of antibiotics both through the direct effect than indirect especially in the category of patients considered "fragile".

Impact of the covid-19 pandemic on multi-drug resistant organisms in a large hospital in palermo (sicily)

Giuseppe Vella¹, Stefano Pizzo², Valerio De Francisci¹, Floriana Bravat¹, Eliana Giambelluca², Dario Genovese¹, Vincenzo Pisciotta¹, Giuseppe Calamusa¹, Emanuele Amodio¹

¹University of Palermo Department of Health Promotion, Mother-Child, Internal Medicine and Specialist of Excellence "G. D'Alessandro" (PROMISE), University of Palermo Via del Vespro, 133, 90127 Palermo Italy, ²University of Palermo

Background and Objective: The pandemic has overwhelmed healthcare systems worldwide. Simultaneously, the rise in multi-drug resistant organisms (MDRO) continues to threaten global health through significant morbidity, mortality, and global economic loss.

This study aims to analyze the impact of the pandemic on the spread of some specific MDRO and define the differences between the pre-pandemic and pandemic period.

Methods: This is an observational study that included adult patients discharged from the University Hospital of Palermo from 01/01/2018 to 31/12/2021. Hospital Discharge Cards of the recruited study patients were linked with reports from the microbiological laboratory to evaluate MDRO isolations. For each patient the SARS-CoV-2 positivity during the hospitalization was evaluated by consulting the surveillance system of the National Institute of Health. The contribution of several risk factors associated with the presence of MDRO was analyzed through logistic regression analysis.

Results:

This study evaluated 58,427 hospitalizations, where half of the patients were over 65 years old (N=26,984) and most admissions were in the medical area (N=31,716). During the hospitalization period, the isolated MDRO were 2,681 (5%), whereas there were 946 subjects (2%) who tested positive for SARS-CoV-2. No statistical difference was found in the prevalence of MDRO in COVID-19 and non-COVID-19 patients. In the multivariable analyses, during 2020 and 2012 there was a statistically significant increased risk of isolation of the following MDRO: *Staphylococcus Aureus*, *Acinetobacter Baumannii*, and *Klebsiella Pneumoniae*. Age, DRG-weight, and length-of-stay were associated to a higher risk of MDRO isolation.

Conclusion: In the study period there was an increasing trend of some MDRO isolations, even more so during the pandemic period. However, SARS-CoV-2 positivity did not impact the risk of contracting MDRO. It is imperative to improve and follow hospital protocols to prevent healthcare-associated infections.

Using legislation to underpin a one health approach to address antimicrobial resistance

Carmen Bullon¹, Maarten der Heijden², Ambra Gobena¹, Camille Loi³, Teemu Viinikainen⁴, Valeria Pasarin⁵, Yingjing Li⁶, Kelsey Galantich⁷

¹FAO Italy, ²WHO, ³WOAH France, ⁴FAO, ⁵FAO Spain, ⁶FAO New Zealand,

⁷WOAH Botswana

The One Health Legislative Assessment Tool for Antimicrobial Resistance (AMR) (the Tool) has been developed by the legal teams of FAO, WHO and WOAH, with inputs from UNEP, through a process of extensive consultation with a range of legal experts across multiple disciplines. The Tool is currently being implemented in four countries prior to a wider rollout and implementation. The Tool assists countries in the identification of regulatory gaps relevant for AMR, and enables the prioritization of solutions through legal reform. It facilitates the examination of a range of legislative instruments and governance arrangements at local, region/province and national levels. Adopting a One Health approach that integrates and sustainably balances the health of people, animals and ecosystems, the Tool targets key regulatory elements in the following sectors (1) AMR governance (2); human health, (3) animal health and production, (4) food safety, (5) pesticide management, (6) plant health and (7) the environment. Under the Tool, cross-cutting themes and the need for multidisciplinary perspectives are emphasized to ensure multisectoral coordinated action against AMR. This Tool is currently being implemented in four countries prior to a wider rollout and implementation. While legislation is just one facet of the range of AMR responses recommended at international and national levels, legislation is often important or essential for many actions identified as a priority in National Actions Plans for AMR. The implementation of the Tool shows how legislation is used to introduce a One Health approach to manage AMR responses. A One Health approach to AMR requires a multidisciplinary response, among them multisectoral coordination mechanisms. In addition to bringing together a range of stakeholders as part of its development process, legislation formalizes and strengthens governance and accountability at local, regional and national levels within and across sectors and actors.

Perspective assessment of the impact of sars-cov-2 pandemic on the use of antibiotics and antibiotic resistance

Caterina Rizzo¹, Caterina Rizzo², Cristina Genovese², Isabella La Spina³, Paola Tripodi², Francesco Giordano², Vanessa Prete³, Carmela Biondo¹, Giovanni Cipriano¹, Alessandro Nicita², Vincenza Fauci¹, Raffaele Squeri¹

¹University of Messina Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina, Italy. Italy,

²University of Messina Department of Biomedical and Dental Sciences and Morphofunctional Imaging, University of Messina, Italy. Torre Biologica, Piano 3 Via Consolare Valeria, snc Policlinico Universitario "G. Martino" Italy, ³University of Messina

Materials and methods

The analysis were performed using two systems: "Farmanalysis", which evaluate pharmaceutical expenditure and antibiotic therapy stream both territorial and hospital; "Health Card (TS)" which allows to investigate individual health spending data to the Internal Revenue Service. These data have been stratified by age group and gender.

Results: Through historical comparison of antibiotic consumption, the highest consumption was observed in the 45 to 64 age group, followed by the over 75 age group. During the pandemic phase and the adoption of containment measures have resulted in a drastic decline in antibiotic prescriptions. A difference of -17.75% was observed in our province compared to the pre-pandemic period resulting in a -25% reduction in healthcare expenditure. At the same time, the shortage of first-class antibiotics led to an overprescription of old-use molecules such as Trimethoprim (+12.93%) and amphenicidics (+27.27%).

Conclusions: Our study demonstrates how the application of social distancing measures and proper use of protective equipment can affect the transmission of airborne diseases and how communication by professionals in the field can increase the informed use of antibiotic therapy by the population. Italy represents together with Greece the tail-end of Europe, so much so that 7-10% of patients encounter a multi-resistant bacterial infection. This issue, therefore, requires a multidisciplinary strategy that involves taking care of the individual from a One Health perspective.

Overcoming the challenges of antimicrobial resistance in developing countries

Muhammad Khan¹, Afreenish Amir², Amna Ali³, Muhammad Waleed⁴, Tarbia Aamir⁴, Aamer Ikram⁵, Rabia Tabassum⁴, Kiran Nisa⁴, Muhammad Khan⁴, Paul Barach⁶

¹Center of Environmental and Occupational Health (CEOH) - National Institutes of Health (NIH), Pakistan) NIH, Pakistan/CDC National Institutes of Health (NIH) Park Road, Chak Shahzad, Islamabad, Pakistan Pakistan,

²National Institutes of Health, Pakistan NIH, Pakistan/CDC National Institutes of Health (NIH) Park Road, Chak Shahzad, Islamabad, Pakistan Pakistan, ³CEOH-NIH NIH, Pakistan/CDC Pakistan, ⁴CEOH-NIH, Pakistan NIH, Pakistan/CDC Pakistan, ⁵National Institutes of Health, Pakistan National Institutes of Health, Pakistan National Institutes of Health (NIH) Park Road, Chak Shahzad, Islamabad, Pakistan Pakistan, ⁶Wayne State University School of Medicine

Background and objective: Antimicrobial resistance (AMR) is a global health challenge and developing countries are more vulnerable to its impacts. High burden of infectious diseases, poverty, weak governance and health systems, and low awareness remain major challenges in the fight against AMR leading to increased prevalence of HAIs including fungal infections, and superbugs like *Candida auris*. Infection-Prevention-Control (IPC) is a key to reduce the emerging HAIs and enhance healthcare outcomes.

Methods: This participatory design project study, led by the National Institutes of Health (NIH)-Pakistan and funded by the CDC, was to support and improve the early diagnosis and surveillance of *C. auris*. We focused on capacity building in laboratory diagnostics, IPC strategies and implementing robust learning data dashboards with provincial stakeholders to ensure effective implementation. After thorough Gap-assessments through site visits and detailed mixed methods at 12 sentinel sites, representing all regions/provinces of Pakistan, using a phase-wise approach, capacity at each site was enhanced by providing hands-on-training and materials to enhance fungal diagnostics, IPC and surveillance.

Results: In Microbiology Diagnostics readiness we found, 2-advanced, 7-intermediate and 3-inadequate sites. IPC program audited using WHO tools indicated 4-advanced, 2-intermediate, 3-basic and 3-inadequate sites. Fungal pathogen identification and transport of samples was initiated. Data dashboards were developed and implemented ensuring robust data collection and sharing

from all sites. 26 samples were received at NIH for final identification indicating different fungal pathogens in isolates. IPC program was initiated and enhanced at all sites.

Conclusions: NIH devised a National Fungal Disease Surveillance System- (NFDSS) to enable rapid diagnosis and surveillance of prevalent fungal pathogens Nationwide. Antimicrobial stewardship involving robust IPC methods can be exploited towards containing AMR in low- and middle-income settings. Adoption of these strategies will assist developing countries overcome their increased vulnerability to growing AMR.

DOI: 10.18332/popmed/164423

Economic and social burden of healthcare-associated infections

Francesco Mennini¹, Paolo Sciatella¹, Angela Ragonese¹

¹Economic Evaluation and HTA (EEHTA CEIS), Department of Economics and Finance, Faculty of Economics, University of Rome "Tor Vergata", Rome, Italy.

Background and objectives: Antimicrobial stewardship (AMS) programs aim to reduce healthcare-associated infections (HAIs) and save healthcare costs associated with antimicrobial resistance (AMR). This study aims to evaluate the economic and social burden of HAIs before and after the implementation of AMS programs, including the use of new antibiotics.

Methods: The study was divided in two phases. In the first phase, the analysis was carried out considering the administrative database of the hospital discharge records from 2006 to 2019. HAIs were detected by selecting all acute hospitalizations with primary or secondary diagnosis related to *Escherichia coli*, *Klebsiella* spp, *Clostridium difficile*, and other unspecified bacterial infections. Data were used to estimate prevalence of HAIs and their impact in terms costs incurred by the NHS. In the second phase, three key opinion leaders (KOLs) were involved: a questionnaire was used to collect additional data on the three Hospital antimicrobial stewardship (AMS) programs, the number of HAIs before and after introducing programs and new antibiotics. Finally, interviews were used to explore the views and experiences of KOLs on AMS and the use of new antibiotics.

Results: HAIs appear on average in 32 cases per 1,000 acute hospitalizations. The occurrence of infections is increasing (22.5 per 1,000 hospitalizations in 2006 and 44.8 per 1,000 in 2019). The valuation of infections resulted in an average annual estimate of approximately € 397 million. The second phase is still ongoing. Preliminary results show a reduction of length of hospital stay (mean 25%, range 14-40%), treatment duration (24%; 14-30%) and antibiotics consumption in DDD (29%; 14-46%).

Conclusion: AMS is a crucial component in the overall effort to combat the spread of AMR. The preliminary results show that implementation of AMS programs reduced antimicrobial use and cost, and lowered the incidence of HAIs.

Awareness of antimicrobial resistance: Google Trends™ analysis to test the success of health promotion initiatives

Enrico Errico¹, Gianfranco Gennaro¹, Francesca Licata¹, Silvia Angelillo¹, Aida Bianco¹

¹University of Catanzaro "Magna Græcia" Department of Health Sciences, School of Medicine, University of Catanzaro "Magna Græcia", Catanzaro, Italy Viale Europa, 88100 Catanzaro CZ, Italy

Background and Objective: Antimicrobial resistance (AMR) is one of the major public health threats of the 21st century. The World Health Organization has highlighted the key role of population empowerment in counteracting AMR. The aim of the study is to assess the impact of selected initiatives on public awareness of AMR using Google Trends™(GT) analysis.

Methods: The impact of World Antimicrobial Awareness Week(WAAW) and World Hand Hygiene Day(WHHD) on public awareness of 'AMR', antibiotics and antibiotic resistance in Sweden, United States, Italy, Japan, Spain and Netherlands from 2017 to 2022 was analyzed, using the relative search volume(RSV) of GT as a surrogate. A joinpoint regression analysis was performed to identify a statistically significant time point of a change in trend. The trends in the different countries were compared by calculating the Z-score.

Results: The analysis of the Z-scores showed a comparable upward trend in all investigated countries. The joinpoint regression did not reveal joinpoints around WAAW and WHHD. Decreasing RSVs of "antibiotics" and "AMR" were shown in all investigated countries, in the period March-May 2020, the decrease is more pronounced in Spain and Italy. In Italy, unlike to other nations, spikes in searches for the term "antibiotics" during the flu-season were displayed.

Conclusion: Results highlight that programs taken into consideration(WAAW and

WHHD) seem not to have sufficiently contributed to raise public awareness of AMR. Enhancing public awareness could help in fight against AMR, but more effective strategies to improve awareness are needed. The decreasing of RSVs during 2020 could be due to COVID-19 pandemic, in particular in Italy and Spain, countries most affected by COVID-19 among those analysed. The spike in the search for the term "antibiotics" in Italy during the flu-season suggests the opportunity to launch public health campaigns to highlight that antibiotics have no effect on the flu.

Patologia Clinica E Microbiologica, A.O.U. San Giovanni di Dio e Ruggi D'Aragona, Largo Città di Ippocrate, 84131 Salerno, Italy

Background and Objective: Healthcare associated infections (HAI) pose a serious threat to public health. The HAI are closely related to antimicrobial resistance (AMR). In 2018 a prevalence study by Suetens et al. coordinated at European level by the ECDC, estimated that 3.8 million patients acquire a HAI each year in Europe, confirming that such infections represent a significant health problem. The consequences that HAI and AMR have on public health can and must be contained with prevention and control actions. In the context of HAI the Surgical Site Infections (SSI) represent one of the most common adverse events occurring in surgical patients. The aim of study is to evaluate the main species involved in SSI and the postoperative antibiotics therapy.

Methods: This is a retrospective study conducted in a.o.u. San Giovanni e Ruggi d'aragona hospitals in salerno, from january 2017 to december 2019. All patients who developed wound infection were included in the study. Incidence and common microorganisms of infection were identified. The identification and antibiotic sensitivity tests were performed with vitek 2. The ibm statistical package for social sciences version 22.00 (spss inc., chicago, il, usa) was used for data analysis.

Results: A total of 82 patients were included in study group. The most common microorganisms isolated were gram-positive (53%) followed by gram-negative (39%) and fungi (8%). enterococcus spp (30.6%) and staphylococcus spp (23.5%) were the main isolated among gram-positive. staphylococcus methicillin-resistant were 45%, and only 1% of enterococcus spp were vancomycin resistance. escherichia coli (13%) and klebsiella pneumoniae (9%) were the most isolated among gram-negative, of these only 35% of isolates were multidrug resistant.

Conclusion: These results may help to the choice of empiric therapy and the antimicrobial prophylaxis strategies in ssi.

Development of prevention of multidrug resistance organisms transmission management participation model of a tertiary care hospital, bangkok Thailand

Kampong Kamnon¹, Kampong Kamnon¹

¹Rajavithi hospital 2 PhayaThai Road Khet Ratchathewi Thailand

Background and Objective: Transmission of multidrug-resistant organisms in hospitals has a direct impact on patients, health care personnel and the hospital. This study was participatory action research and aimed to development of prevention of multidrug resistance organisms transmission management participation model in a tertiary care hospital and also to evaluate the model effectiveness.

Methods: The participation model was used a framework for this study. The model development was composed of three phases. The first phase was concerned with a problem and situation analysis, the second phase of model development and the third phase evaluation model. The model development team consisted of 15

people from the multidisciplinary team and the study sample included 255 people. All data were collected from 51 wards in hospital between November 2021 and September 2022. Data were analyzed using descriptive and content analysis.

Results: The result of the research found that the model prevention of multidrug resistance organisms transmission management participation consisted of 6 elements: 1) providing workshops 2) reviewing of knowledge 3) reminding 4) hand hygiene campaigns 5) supporting protective equipment and medical instruments and 6) evaluation and feedback. More than 92% of the study sample extremely agreed with 6 elements used for prevention of multidrug resistance organisms transmission management.

Conclusion: The results of the research showed the concept of the participation model could be applied to develop a model for prevention of multidrug resistance organisms transmission management participation of a tertiary care hospital.

Antimicrobial resistance surveillance at ospedale policlinico san martino irccs, genoa north-west Italy: A focus on methicillin-resistant staphylococcus aureus

Carlo-Simone Trombetta¹, Marco Bongiovanni², Giulia Gatti¹, Barbara Gugliemi³, Dorotea Bellina⁴, Marco Cappellin³, Roberto Ziffero³, Anna Marchese¹, Andrea Orsi⁵, Nicola Calcavecchia¹

¹University of Genoa Dipartimento di Scienze della Salute (DiSSal), University of Genoa, Genoa, Italy, ²University of Genoa, ³Hygiene Unit, Ospedale Policlinico San Martino IRCCS Genoa, Genoa, Italy Hygiene Unit, Ospedale Policlinico San Martino IRCCS Genoa, Genoa, Italy, ⁴Hygiene Unit, Ospedale Policlinico San Martino IRCCS Genoa, Genoa, Italy, ⁵University of Genoa Dipartimento di Scienze della Salute (DiSSal), University of Genoa, Genoa, Italy; Hygiene Unit, Ospedale Policlinico San Martino IRCCS Genoa, Genoa, Italy

Background/Introduction: Methicillin-resistant Staphylococcus aureus (MRSA) is one of the most common causes of hospital-acquired bacterial infections worldwide. Even though the percentage of MRSA is decreasing in European region, resistance levels remain high in some countries, including Italy, where it currently reaches 30%.

Methods: Microorganisms isolated at Microbiology Unit of Ospedale Policlinico San Martino IRCCS, Genoa, from 1st January 2014 to 30th June 2022 were included. Blood was the only specimen considered. We excluded same patient cases within 30 days one from another and cases where the antimicrobial resistance (AMR) was not tested. Our surveillance includes the same pathogens monitored in the AMR surveillance by European Centre for Disease and prevention and Control (ECDC). In particular, the analysis also included AMR profile of Pseudomonas aeruginosa, Acinetobacter spp, Streptococcus pneumoniae, Escherichia coli, Klebsiella pneumoniae, Enterococcus faecalis and Enterococcus faecium.

Results: Average proportion of MRSA was 54.4% in 2014, 51.3% in 2015, 44.7% in 2016, 41.1% in 2017, 44.2 % in 2018, 43.2% in 2019, 40% in 2020, 36.6% in 2021 and 33.1% in first semester of 2022.

The incidence of MRSA was 2.4/10000 patient-days in 2014, 3.1/10000 patient-days in 2015, 2.9/10000 patient-days in 2016, 2.8/10000 patient-days in 2017, 3.3/10000 patient-days in 2018, 2.8/10000 patient-days in 2019, 3.2/10000 patient-days in 2020, 3.2/10000 patient-days in 2021 and 2.9/10000 patient-days in first semester of 2022.

Conclusions: Since the beginning of the surveillance (2014) the Incidence of MRSA remained stable (2.4-3.3/10000 patient-days). In comparison to the last ECDC AMR Report (2020), however, the proportion of MRSA significantly decreased, but remained above the European average. Further improvements in our infection-control practices are of paramount importance to limit the high mortality related to MRSA bloodstream infections.

A new indicator of prescriptive appropriateness for antimicrobials: The experience of the cristo re general hospital antimicrobial stewardship team

Alessandro D'Avino¹, Martina Sapienza², Daniela Grande¹, Arcangelo Schiattarella¹, Paolo Dionisi², Martina Dolce¹, Giovanni Brandimarte¹, Micaela Carnali¹, Gabriella Nasi¹

¹"Cristo Re" General Hospital -Rome Italy, ²"Cristo Re" General Hospital -Rome

Background: Antibiotic resistance is being a crucial issue in our hospitals, and its control, which is one of the most challenging task for the future, passes through an appropriate use of antibiotics. To evaluate the prescriptive appropriateness of

antimicrobials, we recently created a new indicator which takes into account the rate of infections together with antimicrobial consumption and the median time of treatment of each event.

Methods: The "Estimated Prescriptive Appropriateness Rate" (EPA-SCORE) " has been calculated for each group of bacteria, as the rate between the observed consumption of an antibiotic (DDD/1000days of hospitalization) and the expected one as if the same antibiotic had been used for 10 days exclusively for the observed infections where it was indicated, according to the following formula:

$EPAScore = DDD(observed/expected) * (1/N. \text{ of infections})$

Data from January 2020 and June 2022 were collected while restrictive and persuasive strategies of Antimicrobial Stewardship were implemented. Changes in EPA-SCORE were evaluated through the years.

Results: In our hospital, in the first semester of 2022 prevalence of ESBL+ Gram negative-infections was 0.90 cases/1000 doh/year. The observed consumption of drugs indicated for those infections was 86.9 DDD/1000 doh, whilst the expected one for the registered number of infections was 9.01 DDD/1000doh, with an EPAScore of 10.37%.

Regarding multi-drug-resistant gram negative-infections, prevalence was 1.48/1000doh/year; observed antibiotic consumption for them (whose prescription policy was restricted to ID specialists) was 43DDD/1000doh, whilst the expected DDD was 29.6 DDD/1000doh (EPAScore 67.7%)

Comparing data between the first semester of 2020 and the same period of 2022, a significant increase in EPAScore was detected (+4.2% and +7.1% for ESBL+ and MDR Gram-negative infections in 2022 respectively)

Conclusion: Our data demonstrate that the EPAScore could represent a feasible indicator of appropriateness of antimicrobial prescription, and restrictive strategies of antimicrobial stewardship can help to improve its outcome.

Access and use of antibiotics in a group of migrants in a locality of bogota colombia in 2021

Jovana Cañas¹, Sebastian Rueda², Oscar Acevedo³, Juan Cuya⁴, Muhammad Zaman⁵

¹Facultad de Medicina Universidad de los Andes Profesor Asociado "Cra 1 N° 18A - 12 Bogotá - Colombia Postal code: 111711" Colombia, ²Facultad de Medicina Universidad de los Andes, ³Facultad de Medicina Universidad de los Andes Profesor Titular "Cra 1 N° 18A - 12 Bogotá - Colombia Postal code: 111711" Colombia, ⁴Facultad de Medicina Universidad de los Andes Investigador Junior "Cra 1 N° 18A - 12 Bogotá - Colombia Postal code: 111711" Colombia, ⁵Universidad de Boston

Colombia is host to approximately 1.8 million migrants according to the United Nations High Commissioner for Refugees (UNHCR) by mid-2020, making it the second country worldwide after Turkey to host the largest quantity of migrant population (1) The absence of regulatory policies in Latin America concerning certain types of medication permits the sale and distribution of antibiotics without prescription, thus making self-medication a serious problem (4,5). In the case of antibiotics, the result is not only an increase in antibiotic resistance in the migrant population but also exposing the general population to this issue (6). The objective of this study is hereby to describe the access to and use of antibiotics in a group of migrants in a locality of Bogota, Colombia in 2021, for which we will identify factors that influence both the access to and use of these medications, as well as characterize some perceptions from healthcare professionals concerning antibiotic resistance in this population. The study methodology is observational, and descriptive, the cross-sectional type. In the migrant group, the important percentage of people who do not follow any instructions in specific regarding the duration of treatment, as well as those who use them according to non-professional indications, such as those coming from family members or neighbors, as well as in an "as needed" manner. This could also be a result of the fact that a significant part of the group stops taking their antibiotics when feeling better. Regarding the pharmacist group, issues such as non-professional formation, indications given to clients based only on experience but not on guidelines, and incomplete doses bought from clients, give us an idea about those factors that may be influencing some antibiotic usage patterns that ultimately could have an impact on antibiotic resistance.

In vitro antibacterial and antifungal activities of extracts and fractions of leaves of *Ricinus communis* Linn against selected pathogens

Bedaso Kassaye¹

¹Ethiopian Agriculture Authority, Ethiopia

Background and Objectives: Infectious disease impacts are reduced due to the development of antimicrobial agents. However, the effectiveness of antimicrobial agents is reduced over time because of the emergence of antimicrobial resistance. To overcome these problems, scholars have been searching for alternative medicines. *Ricinus communis* is used as a traditional treatment for bovine mastitis, wound infection, and other medicinal purposes. The objective of the present study was to further evaluate the antimicrobial activities of *R. communis* leaf extracts and fractions. Methods: *R. communis* leaves were macerated in methanol and acetone. The methanol extract showed better antimicrobial activity and subjected to further fractionation via increasing polarity of solvents (n-hexane, chloroform, ethyl acetate, and aqueous). Test microorganisms included in the study were six laboratory reference bacteria (*Escherichia coli*, *Staphylococcus aureus*, *Streptococcus agalactiae*, *Klebsella pneumoniae*, *Pseudomonas aeruginosa* and *Streptococcus pyogenes*), two clinical isolate bacteria (*E. coli* and *S. aureus*), and *Candida albicans*. The agar well diffusion method was employed to determine antimicrobial activity. The minimum inhibitory concentrations (MIC) and minimum bactericidal/fungicidal concentrations (MBC/MFC) were determined through broth microdilution.

Results: The results indicated that the best antimicrobial activity for ethyl acetate fraction ranged from 14.67 mm (clinical *E. coli*) to 20.33 mm (*S. aureus*) at 400 mg/ml, however, n-hexane exhibited the lowest antimicrobial activity. Among the tested fractions, ethyl acetate fraction showed the lowest MIC values ranged from 1.5625 mg/ml (*S. aureus*) to 16.67 mg/ml (*Candida albicans*). Conclusions: The ethyl acetate fraction showed bactericidal activity against all tested microorganisms. Hence, ethyl acetate fraction of crude methanol extract exhibited the best antimicrobial activity. Keywords: antibacterial, antifungal, *ricinus communis*, selected pathogens, crude extracts, solvent fractions

Disease assessment and antimicrobial prescription patterns in Sonali Chicken cases in Bogura, Bangladesh

Ibrahim Khalil^{1,2,3}

¹Department of Livestock Services (DLS), Bangladesh, ²Field Epidemiology Training Program for Veterinarians Fellow and Scientific Officers, Bangladesh, ³One Health Institute, Bangladesh and Field Disease Investigation Laboratory (FDIL), Barishal, Bangladesh

Sonali chicken production increased substantially during the last two decades in Bangladesh. However, different prevalent diseases hampered its normal growth. Irrational and inappropriate use of antimicrobials is commonly occurred which contribute to the development of antimicrobial resistance (AMR). The current study was therefore attempted to assess the burden of diseases along with antimicrobial prescription patterns. A total of 1690 drug prescriptions for infectious diseases in Sonali chickens in Bogura during 2020-2021 was extracted from the e-prescription database of 3769 poultry cases for assessing the disease status and antimicrobial prescription patterns. Data extracts were entered into MS excel and cleaned and sorted before exporting to STATA/SE-13 for epidemiological analysis. The proportion of cases was dominated by mixed diseases of viral, bacterial and other infectious cases (28 %, n=474), followed by viral diseases (17.5 %, 296), bacterial diseases (4.5 %, 76), protozoan disease (4.0 %, 67). Antibiotics were widely prescribed regardless of case type (84.4- 97% cases). The highest proportion of antimicrobials was used in protozoan cases (97 %, 65), followed by viral alone (92%, 273), mixed (91.7%, 435) and bacterial alone (90.8%, 69). Single antibiotics (61.3%, 980) were prescribed widely followed by combined (14%, 224) and double (2.4%, 39). Tylvalosin (42%, 669) was more commonly prescribed for almost all disease types. Different fluoroquinolones and florfenicol were predominantly prescribed for undiagnosed (11.8%, 70) and bacterial cases (16%, 11), respectively. Colistin combined (3.4%, 55) was prescribed highly followed by aminoglycosides (2.4%, 38). Moreover, antiviral drugs were prescribed for 33.5% viral, 33% bacterial, and 30% protozoan cases. Immuno-stimulant was prescribed for 18% viral and bacterial cases. Considering the results, it is practical to include this e-prescription system to existing web-based surveillance system to know the disease rank and antimicrobial use pattern timely, thus support to preventive program and antimicrobial stewardship approach.

Mapping and characterizing early warning systems for emerging profiles of antimicrobial resistance in Italy: a national survey

Jessica Iera^{1,2}, Chiara Seghieri³, Lara Tavooschi⁴, Claudia Isonne⁵, Valentina Baccolini², Daniele Petrone^{6,7}, Lorenzo Bandini⁶, Adriano Grossi⁶, Fortunato

D'Ancona⁶

¹Management and Health Laboratory, Institute of Management - Department EMbeDS, Sant'Anna School of Advanced Studies, Pisa, Italy, ²Department of Public Health and Infectious Diseases, Sapienza University of Rome, Italy, ³Management and Health Laboratory, Institute of Management - Department EMbeDS, Sant'Anna School of Advanced Studies, Pisa, Italy, ⁴Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, ⁵Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy, ⁶Department of Infectious Diseases, Istituto Superiore di Sanità, Rome, Italy, ⁷Department of Statistics, Sapienza University of Rome, Italy

Background and Objective: Antimicrobial resistance (AMR) surveillance systems available at national level in Italy are currently lacking an alert system to timely detect emerging profiles of AMR with potential relevance to public health. Moreover, early warning systems (EWS) existence at subnational level is unclear. This study aims at mapping and characterizing EWS for microbiological threats at regional level in Italy, focusing on emerging AMR, and at outlining potential barriers and facilitators to their development/implementation.

Methods: A web-based survey was developed following consensus among several experts. A three-section questionnaire was then administered, from June to August 2022, to Italian regional representatives for antimicrobial resistance, whose participation was on a voluntary basis.

Results: In total, 20 out of 21 Regions and Autonomous Provinces (95,2%) responded to the survey. Among those, nine (45%) reported the implementation of EWS for microbiological threats at regional level, three (15%) reported that EWS are in the process of being developed, eight (40%) reported that EWS are currently not available. EWS characteristics varied widely among the identified systems, concerning both AMR profiles that are expected to be reported and data flow. Technological issues and lack of cooperation among microbiology laboratories emerged as barriers that need to be addressed in the process of strengthening national AMR surveillance systems.

Conclusions: The results of this study depict a highly heterogeneous scenario: less than half of Italian regions have implemented alert systems at regional level, differing widely in their characteristics, while EWS for microbiological threats - including emerging AMR - are available mainly at local level, suggesting that more efforts aimed at strengthening national AMR surveillance systems should be made, including the achievement of a strong cooperation between the regional and the central levels.

Effectiveness of antimicrobial stewardship programmes on antibiotic consumption - a systematic review and meta-analysis

Kyaw Ya^{1,2}

¹Swiss Tropical and Public Health Institute, Allschwil, Switzerland,

²University of Basel, Switzerland

Background and Objectives: Antimicrobial resistance (AMR) continues to emerge rapidly globally. Little evidence exists on the impact of antimicrobial stewardship programmes (ASPs) on the consumption of antibiotic across healthcare and income settings. The main objective of this review is to synthesize current evidence in this area.

Methods: We searched PubMed, Web of Science, and Scopus databases from 1 Aug 2010 to 1 Aug 2020 and also additional studies from the bibliography sections of previous systematic reviews. We used the Effective Public Healthcare Panacea Project quality assessment tool to assess study quality. We measured the pooled effect of targeted ASP on antimicrobial consumption, using multi-level random effects models. The main outcome measures were proportion of patients receiving an antibiotic prescription and Defined Daily Doses per 100 patient days. **Results:** We identified 52 studies that measured the effect of ASPs on antimicrobial consumption. 40 studies were conducted in high income countries (HICs), and 12 in low and middle-income countries (LMICs). On average, ASPs reduced antibiotic prescriptions by 10% (95% CI [-15% to -4%]), and antibiotic consumption by 28 % (RR=0.72, 95% CI [0.56 to 0.92]). ASPs were also associated with a 79% reduction in antibiotic consumption in paediatric hospitals (95%CI [-64% to -5%]) and a 28% reduction in WHO watch groups antibiotics, RR = 0.72, 95% CI [0.56 to 0.92]. Reductions were observed across all broad-spectrum antibiotic classes: fluoroquinolones (42% reduction), Penicillin/beta-lactamase inhibitor combinations (42% reduction), carbapenems (31%), macrolides (26%) and cephalosporins (15%), though these were not statistically significant. No change in penicillin consumption was identified.

Conclusions: ASPs are effective in reducing antibiotic consumption in both hospital and non-hospital settings. Impact assessment of ASPs in resource-

limited settings remain scarce; further research is needed on how to best achieve reductions in antibiotic use in LMICs.

Keywords: antimicrobial resistance, antibiotic consumption, antimicrobial stewardship programmes

Establishing polymerase chain reaction-based diagnostic test for the detection of drug resistant *Salmonella typhi* in a hospital setting in the Philippines

Jan Evangelista^{1,2}

¹School of Tropical Medicine and Global Health, Nagasaki University, Japan,

²San Lázaro Hospital-Nagasaki University Collaborative Research Office, Manila, Philippines

With the increasing use of polymerase chain reaction-based technologies to diagnose diseases such as tuberculosis and severe acute respiratory syndrome coronavirus 2 in the Philippines, medical technologists are becoming more familiar with novel molecular techniques. However, development of polymerase chain reaction diagnostic assays based on the identified needs of healthcare facilities and surrounding communities remains uncommon. In this work, we outline the experience and challenges we faced when developing a set of conventional polymerase chain reaction-based diagnostic tests for *Salmonella typhi* and associated sulfonamide (Sul2), chloramphenicol (CatP), penicillin (Tem), and fluoroquinolone (gyrA) drug resistance genes in San Lázaro Hospital-Nagasaki University Collaborative Research Laboratory. This process involved three key components: procuring the necessary reagents, generating a positive control, and optimizing the polymerase chain reaction itself. To generate positive control, we re-cultured 21 archived isolates of *Salmonella* species on MacConkey agar and performed matrix assisted laser desorption ionization-time of flight mass spectrometry. Subsequently, genomic deoxyribonucleic acid was extracted from the identified colonies. Polymerase chain reaction optimization commenced by determining the optimal annealing temperatures. Good intensity of amplicon bands were observed at annealing temperatures 58°C for nested polymerase chain reaction and 45°C for conventional monoplex polymerase chain reaction. During optimization, we successfully detected flagellin gene (fliC) for *Salmonella typhi* and three resistance genes (gyrA, Sul2, and Tem) using positive control. Conversely, CatP gene was not detected. However, when we ran clinical samples, two of 18 *Salmonella typhi* polymerase chain reaction-positive specimens were positive for CatP gene. Our work may serve as a useful example for other laboratories and medical technology professionals in the country in responding to locally identified diagnostic needs. Moreover, early detection of resistance genes can inform both public health decision-making and individual clinical practice.

Keywords: conventional polymerase chain reaction, *Salmonella typhi*, drug resistance

Genomic comparison of *A. baumannii* isolated from COVID-19 and non-COVID-19 patients admitted to an Intensive Care Unit: preliminary results

Mariateresa Ceparano¹, Mariateresa Ceparano¹, Valerio Capitani², Claudia Isonne¹, Valentina Baccolini¹, Giuseppe Migliara¹, Carolina Marzuillo¹, Paolo Villari¹

¹Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy, ²Department of Public Health and Infectious Diseases, Sapienza University of Rome, Sapienza, Italy

Background and Objective: *A. baumannii* is a major responsible of infections in patients admitted to the intensive care unit (ICU). In Policlinico Umberto I in Rome, *A. baumannii* was the main microorganism isolated in ICU SARS-CoV-2 patients, and high clonal transmission profiles were documented. The purpose of this study was to compare the clonal profiles detected in COVID-19 patient's samples with those obtained from non-COVID-19 patients admitted to the same unit.

Methods: Bacterial isolates of *A. baumannii* were collected between January 2020 and January 2022. The isolates were typed by pulsed field electrophoresis to analyze their homology relationships.

Results: A total of 587 COVID-19 patients and 304 non-COVID-19 patients were admitted to the ICU. They were predominantly male (N=398 and N=186, respectively) with a mean age of 63.5 years in the first group and 61.6 years in the second group. Genotypic analysis of 138 isolates in COVID-19 patients revealed two main patterns (A and B) and a few minor patterns. Patterns "A" (59.4%) were found throughout the study period, patterns "B" (35.5%) were isolated from October 2020 to March 2021. In non-COVID-19 patients, 67 isolates that showed

more heterogeneous clonal profiles were typed. However, the pattern "A" (47.7%), was the most frequent pulsotype detected during the study period. The strains had high antibiotic resistance profiles and were isolated mostly from tracheobronchial aspirates and rectal swabs both in COVID-19 (42.8% and 29.6%) and in non-COVID-19 patients (34.3% and 42.8%).

Conclusions: The identification of the pattern "A" in both cohorts of patients, may indicate the possible transfer of related isolates from one ICU to another in the same hospital among patients or through healthcare workers. Therefore, the use of strict infection control strategies to reduce cross-contamination of endemic clones of *A. baumannii* isolates is essential.

DOI: 10.18332/popmed/165723

Emergence of NDM-1-producing ST147 *Klebsiella pneumoniae* strains isolated from bloodstream infections during the COVID-19 pandemic, Southern Italy

Maria Chironna¹, Daniela Loconsole¹, Francesca Centrone¹, Anna Sallustio¹, Daniele Casulli¹, Marisa Accogli¹

¹University of Bari, Italy

Background and Objective: Carbapenem-resistant Enterobacterales (CRE) infections are a major public health threat worldwide. The presence of NDM-producing *Klebsiella pneumoniae* (NDM-KP) has increased in several regions, mainly during the COVID-19 pandemic. The study aimed at describing a regional outbreak of NDM-KP identified in bloodstream infections (BSI) in the Apulia region of Italy.

Methods: From January 2020 to September 2022, 459 carbapenem-resistant-KP (CR-KP) strains collected from patients hospitalized with BSI were subjected to molecular characterization at the Laboratory of Molecular Epidemiology and Public Health of the University Hospital Policlinico of Bari (Italy) through a commercial multiplex real-time PCR kit (GeneXpert platform, Cepheid) for the identification of the carbapenemase-encoding genes blaKPC, blaVIM, blaNDM, blaIMP and blaOXA-48. In addition, a subset of 27 NDM-KP randomly selected strains were subjected to NDM variant detection by real-time PCR assay and to multi-locus sequence typing (MLST).

Results: The blaKPC gene was identified in 67.5% of KP isolates, blaVIM in 0.2%, blaNDM in 20.3%, blaOXA-48 in 3.1%. Carriage of multiple carbapenemase genes was reported in 12 isolates (11 blaNDM+blaKPC and one blaKPC+blaVIM). Overall, 104 strains carrying the blaNDM gene were identified (22.6%). The 69.2% was identified in male subjects. The average age was 67 years (range: 29-92) and the province of residence was Brindisi for 35.6%, and Taranto for 41.3% of patients. Forty-four patients (42.3%) were positive for SARS-CoV-2. Further characterization of 27 NDM-KP strains revealed that all the strains were ST147-NDM-1-KP.

Conclusion: The prevalence of NDM-KP in the Apulia region has increased from 0.2% in 2014-2016 to 22.6% in 2020-2022, thus representing a matter of concern. Implementation of molecular epidemiology of CRE is crucial to limit hospital infections. Moreover, timely and appropriate diagnosis, high standards of infection prevention and control, and antimicrobial stewardship are key actions to control the spread of antimicrobial resistance worldwide, particularly in hospital settings.

Antibiotic resistance genes and viral genomes assessment in wastewater samples from cabo verde wastewater treatment plants

Isabel Araujo¹, Tamar Monteiro¹, Kleidi Monteiro¹, Maria Barreto Crespo², Mónica Nunes²

¹Universidade de Cabo Verde, Faculdade de Ciências e Tecnologia, Zona K, Palmarejo - Praia, Ilha de Santiago, República de Cabo Verde, 7943-010, Cape Verde, ²Instituto de Biologia Experimental e Tecnológica, Apartado 12, 2781-901 Oeiras, Portugal

Background and Objectives: Reusing treated wastewater is a sustainable and recommendable strategy, especially in a nation where water shortage is a major issue. As a result, increasing the use of treated wastewater in agriculture is a sine qua non condition. However, conventional wastewater treatment plants are sometimes ineffective in removing emerging microbiological contaminants such as resistant bacteria and antibiotic resistance genes, as well as human pathogenic viruses, and are thus considered sites of antibiotic resistance proliferation and spread.

The aim of this study was to evaluate the presence of antibiotic-resistant bacteria/genes (ARB/ARG) as well as human-pathogenic viral genomes in water from wastewater treatment plants.

Methods: ARG and viral genomes were detected by multiplex qPCR methods in the influent and treated effluent of six WWTPs chosen in the islands of Cabo Verde.

Meropenem or ciprofloxacin were added to a selective medium to help isolate bacteria resistant to these AB, and the EUCAST disc diffusion technique was used to analyse the AB resistance phenotypes of possibly pathogenic bacteria.

Finally, we extracted plasmids (using a kit from Nzytech) from five prominent clones of each influent sample to analyse the variety of Adenovirus and Polyomavirus in Cape Verde.

Results: Polyomavirus, adenovirus, norovirus GII, hepatitis A and hepatitis E genomes were detected at high concentrations (106 gc/L) in either the influent or effluent samples, as were carbapenem and fluoroquinolone resistance genes at concentrations of 1010 gc/L.

Conclusion: These findings indicate that conventional treatments currently being used in the investigated WWTPs are insufficient to effectively remove ARG and viral genomes, which highlights the need for the development and implementation of targeted treatments at full scale in the WWTPs so that the produced effluents can be safely discharged into the environment and/or recycled for uses like agricultural irrigation (ensuring food security).

Impact of a structured antimicrobial stewardship program in Cittadella Hospital, Padua, Italy

Emanuela Zilli¹, Antonio Miotto¹, Giulia Zavatta², Elisa Baldasso¹, Giampaola Basso¹, Mara Carraro², Suada Tikvina³, Antonella Ruffatto¹, Emanuela Zilli³

¹Azienda ULSS 6 Euganea, Hospital Direction, Cittadella Hospital, ULSS 6 Euganea, Via Casa di Ricovero 40, Cittadella, Italy, ²Azienda ULSS 6 Euganea, ³Department of Cardiac, Thoracic, Vascular Sciences and Public Health, University of Padua, Italy

Background and Objective: Cittadella Hospital (Padua) has 400 beds and serves a territory of 240,000 inhabitants. Regarding antimicrobial stewardship program, special focus was put on fluoroquinolones, carbapenem and third generation cephalosporins. A reduction > 5% of fluoroquinolones use was directly demanded by the Italian National Action Plan against antimicrobial resistance; third generation cephalosporins are some of the most prescribed antibiotics in the hospital settings.

Methods: Appropriate use of antibiotics was encouraged during periodic multidisciplinary meetings held by the Hospital Infection Control Committee (made up of Hospital Antimicrobial Stewardship Task Force, Infectious Disease Consultant, Microbiologist, Pharmacist etc.).

Results: The Pharmaceutical Service provided a quantitative estimate of antibiotic consumption, expressed in Defined Daily Dose (DDD) per 100 bed-days. Between 2019 and 2022, a large decrease in the consumption of carbapenems in Intensive Care Unit (from 15.3 to 15.2 DDD, - 0.6%) and in Medical wards (from 6.2 to 3.1 DDD, - 50.0%) was reported; a decrease in the consumption of quinolones in Intensive Care Unit (from 22.4 to 13.0 DDD, - 41.9%), Medical wards (from 11.9 to 7.3 DDD, - 38.6%) and Surgical wards (from 12.0 to 7.6 DDD, - 36.6%) was highlighted; a small decline in the consumption of third generation cephalosporins in Medical wards (from 17.4 to 17.2 DDD, - 1.1%) was reported. Finally, a decrease in the consumption of macrolides was reported in the Intensive Care Unit (from 9.7 to 3.1) and Medical wards (from 9.0 to 8.9).

Conclusion: Periodic multidisciplinary meetings aimed at medical referrals for infections, constant monitoring of antimicrobial consumption and timely identifying of warning situations that may need a specific intervention are the cornerstone of Antimicrobial Stewardship programs, together with analyzing data of bacterial resistance rates and infections from multi-drug resistant bacteria.

Multidrug-resistant Cause Mortality Rates in infants Infected with Carbapenem Resistant Organisms

Waiswa Moses¹, Kalembe Janat², Paulson Henderson³

¹Uganda Development and Health Associates, Iganga General Hospital, Iganga, Uganda, ²Iganga General Hospital, Uganda, ³School of Clinical Medicine, Makerere University

Background: Multidrug-resistant, Gram negative infections particularly due to Carbapenem resistant organisms (CRO), have increased globally. Few studies have reported on the burden of CRO in infants from hospital settings in Uganda. This study aimed to determine the incidence and mortality rates of culture-confirmed Gram negative infections, with a special focus on CRO in a neonatal unit. **Methods:** Positive bacterial cultures from the sterile sites of infants admitted in the neonatal clinic from the 1st of January 2018 to 31st December 2019 were reviewed respectively. Type of organism, susceptibility and outcomes were recorded. Data on Gram- negative isolates, including the CRO, were extracted,

rates and outcomes were analysed.

Results: There were 2219 neonates with organisms isolated from sterile sites (blood and cerebrospinal fluid), according for all 30% admissions, giving a neonatal sepsis incidence of 17.9/1000 patient-days. There was a total of 1746 positive isolates (excluding coagulase negative staphylococcus). Of these 1706, (98%) were isolated from blood, and 40 (2%) from cerebrospinal fluid. Overall 1188 (68%) were Gram negative, 371 (21%) Gram-positive and 187 (10.7%) fungal isolates. The common Gram-negatives were *Acinetobacter baumannii* (526/1188:44%) and *Klebsiella pneumoniae* (469/1188:40%). Carbapenem resistance was observed in 359 (68%) of the *Acinetobacter baumannii* (CRAB) and in 103 (18%) of the Enterobacterales (CRE) isolates, with 98% of CRE being *Klebsiella pneumoniae* (CR-klebs). Twenty-four 41% of *Pseudomonas* species were carbapenem resistant. **Conclusion:** We observed a high incidence of positive cultures from sterile sites. The common organism isolated were Gram-negatives, among these carbapenem resistance was high and was associated with high mortality. Mortality was higher in infants with CRE compared to those with CRAB.

DOI: 10.18332/popmed/164031

Cost-effectiveness of Imipenem/Cilastatin/Relebactam compared to Colistina-Imipenem for the Treatment of Confirmed Carbapenem Non-Susceptible Gram-negative Bacterial Infections

Andrea Marcellusi¹, Martina Paoletti², Francesco Mennini¹, Joe Yang¹

¹Centre for Economics and International Studies-Economic Evaluation and Health Technology Assessment, Faculty of Economics, University of Rome "Tor Vergata", via Columbia 2, 00133 Rome, Italy, ²MSD United States

Background and Objective: Antimicrobial resistance (AMR) is an important public health problem with a strong epidemiological, economic, and social impact. The objective of this analysis was to evaluate the cost-effectiveness of imipenem/cilastatin/relebactam treatment compared to colistin-imipenem in the treatment of hospitalized patients with gram-negative bacterial infection caused by imipenem-resistant pathogens.

Methodology: To simulate a cohort of patients a mixed model was developed, structured in two sections for simulation in the methodology short and long-term evolution of the patients in analysis. Modelled patients were those with hospital-acquired bacterial pneumonia/ventilator-associated bacterial pneumonia (HABP/VABP), complicated intra-abdominal infection (cIAI) or complicated urinary tract infection (cUTI) caused by carbapenem-resistant Gram-negative (GN) pathogens. The model begins with a short-term decision tree describing possible treatment routes and outcomes for patients during the hospitalization period. After treatment, patients are classified as cured, not cured or dead (the proportion of which depends on the data on the efficacy and mortality of the treatments). Patients who have not recovered from the initial treatment remain to receive a subsequent line of therapy. Those who are alive but not cured at the end of the decision tree are assumed to die within one year, which is broadly in line with clinical expert opinion. Patients who are healed in the decision tree in the long-term Markov model, designed to capture the follow-up costs and health-related quality of life (HRQL) of patients healed over their lifetime.

Results: The analysis, conducted on a hypothetical cohort of 1000 patients, highlights how imipenem/cilastatin/relebactam is advantageous. In fact, it is dominant compared to colistin-imipenem both in the National Health System (NHS) and in the social perspective since, compared to an average saving of € 2,800.15 and € 3,174.63 respectively, it would generate an increase of 4.76 years of life and 4.12 quality-adjusted life years (QALY) per patient.

Popul. Med. 2023;5(Supplement):A145

"Drug resistance index": A new public health indicator for antibiotic resistance

Riccardo Amicosante¹, Eleonora Cimino¹, Raffaella Golini¹, Riccardo Amicosante¹, Alessandro Ferranti¹, Giovanna Micolucci², Anna Lepore², Mario Muselli¹, Leila Fabiani¹, Stefano Necozione¹

¹University of L'Aquila, Italy, ²Asl 1 abruzzo Italy

Introduction: In the last years *Klebsiella pneumoniae* (*K. pneumoniae*) showed worrying levels of antibiotic resistance with significant differences between countries. We used the Drug Resistance Index (DRI) with the aim of identifying antibiotic effectiveness differences in the European Region.

Materials and Methods: We calculated, and compared *K. pneumoniae* related DRI in Italy, France, and Spain for the years 2009, 2011, 2013, and 2015. DRI was calculated by multiplying proportion of consumption of selected antibiotic class and proportion of all *K. pneumoniae* resistant to that antibiotic class. Prevalence of resistance data were obtained by consulting the national surveillance

system (Italy), and the ECDC surveillance system (France and Spain). Antibiotic consumption data were extrapolated from the Italian Medicines Agency (Italy) and the Center for Disease Dynamics, Economics and Policy system (France and Spain).

Results: Among the classes of antibiotics considered, the highest prevalence of resistance in Italy was for Cephalosporins; the lowest for Carbapenems. The highest prevalence of resistance in France and Spain was for Fluoroquinolones; the lowest for Carbapenems. In Italy and Spain, the higher consumption was recorded for Fluoroquinolones. In France the consumption of Cephalosporins was the highest.

DRI was different in the countries considered, however the trend was similar: increase from 2009 to 2013 and stabilization in 2015. Italian DRI was 27.4% in 2009 and increased in the following years (45.3% in 2011; 54.0% in 2013; 53.8% in 2015). Spanish DRI was 13.2% in 2009, increasing to 14.9% in 2011, and 20.2% both in 2013, and 2015. French DRI increased throughout the period considered: 20.6% in 2009 to 26.0% in 2011, 28.2% in 2013 and 30.0% in 2015.

Conclusions: Regional and temporal differences in DRI suggest the need for international action to face antibiotic resistance.

DOI: 10.18332/popmed/164206

Klebsiella pneumoniae drug resistance index: an indicator evaluated in l'aquila hospital

Raffaella Golini¹, Eleonora Cimino¹, Riccardo Amicosante¹, Alessandro Ferranti¹, Giovanna Micolucci¹, Anna Lepore¹, Mario Muselli¹, Leila Fabiani¹, Stefano Necozione¹

¹University of L'Aquila Italy

Introduction: Antibiotic resistance is a critical public health issue, both clinically and economically. *Klebsiella pneumoniae* (*K. pneumoniae*) is a common cause of healthcare-associated infections and has worrying levels of antibiotic resistance. The antibiotic resistance of *K. pneumoniae* was investigated in the L'Aquila Hospital using the Drug Resistance Index (DRI), a measure of antibiotic effectiveness whose validity was subject of discussion.

Materials and methods

DRI was calculated by multiplying proportion of consumption of selected antibiotic class and proportion of all *K. pneumoniae* resistant to that antibiotic class. The DRI in the L'Aquila Hospital for the years 2019 and 2020 have been calculated and then compared to national DRI. Local resistance and antibiotic consumption data were obtained by analysis laboratory of the L'Aquila Hospital, and by the Management Control Office. National data were obtained by the national surveillance system on antibiotic resistance, and by the Italian Medicines Agency.

Results: The local prevalence of resistance to β -lactamases was higher than those to carbapenems in both years: 35.6% vs 15.7% in 2019; 32.0% vs 17.6% in 2020. Prevalence of resistance to β -lactamases showed a reduction from 35.6% to 32.0%; instead, prevalence of resistance to carbapenems increased from 15.7% to 17.6%. L'Aquila Hospital DRI was 29.9% in 2019 and 28.9% in 2020. In Italy, the prevalence of resistance against β -lactamases was higher than those to carbapenems in both years: 60.0% vs 34.7% in 2019 and 57% vs 33.0% in 2020. National DRI was 57.7% in 2019 and 54.3% in 2020. In 2019 and in 2020 the most consumed antibiotics were β -lactamases, the less were carbapenems.

Conclusions: DRI calculated in L'Aquila Hospital was significantly lower than the national, but both showed a downward trend, indicating an improvement in the management of antibiotics.

Methicillin-resistant and methicillin-sensitive staphylococcus aureus infections in patients undergoing elective arthroplasty surgery: a prospective observational multicentre study

Pietro Vernaci¹, Antonino Cannistrà², Gianfranco Barra², Marco Provenzano², Leandro Gentile¹, Anna Odone¹

¹University of Pavia Department of Public Health, Experimental and Forensic Medicine, University of Pavia, Pavia, Italy, ²San Donato Hospital Group Clinical Institutes of Pavia and Vigevano, Italy

Background and objective: *Staphylococcus aureus* is a leading cause of surgical site infections. Risk factors are age, comorbidity and prolonged hospitalization. Since up to 45% of *S. Aureus* infections are Methicillin-resistant, targeted treatment are required to stop nosocomial infection following surgical procedures. In order to explore the incidence and management of methicillin-resistant and methicillin-sensitive *S. Aureus* (MRSA and MSSA) infections, a prospective observational multicentre study was conducted in patients undergoing elective arthroplasty surgery at the Clinical Institutes of Pavia and Vigevano (Italy).

Methods: We examined data flow from screening nasal swabs performed within 30 days before surgery (arthroplasty surgery or prosthetic revision) in patients treated between March and November 2022. Eradication treatment consisted in nasal drainage with Mupirocin twice a day and skin washings with 4% chlorhexidine or 7.5% povidone iodine or 2% triclosan once a day.

Results: A total of 737 subjects were recruited, 37% men and 63% women. The average age was 72 years, with the following distribution: 39-52 years, 3.7%; 53-62 years, 13.2%; 63-72 years, 32.5%; 73-82 years, 41%; 83-92 years, 9.6%. Seven (0.9%) patients were MRSA positive and 142 (19.3%) MSSA positive. The outcome of the MRSA eradication treatment will be evaluated through an Active Registry reporting infectious or secondary events (movement impairment, persistent joint pain, inflammation signs) during the follow-up phase performed at 6 and 12 months either on site or by telephone.

Conclusions: The early identification of MRSA strains through patients screening allows targeted antibiotic treatment to prevent surgical site infections. Further prospective studies are needed in order to characterise population contamination and define the best therapeutic strategies.

Antibiotic resistance in ocular bacterial infections: an integrative review of ophthalmic chloramphenicol

Emmanuel Elebesunu¹, Emmanuel Elebesunu¹

¹University of Nigeria, Enugu, Nigeria Department of Medical Laboratory Sciences, Faculty of Health Sciences and Technology, University of Nigeria, Enugu, Nigeria Faculty of Health Sciences and Technology, University of Nigeria, Enugu Campus, 400105, Enugu, Nigeria

Background: Chloramphenicol is a broad-spectrum antibiotic widely used for treating ophthalmic infections, but concerns about rising bacterial resistance to chloramphenicol have been observed due to its frequent use as an over-the-counter medication. This review assessed the rates of drug resistance to chloramphenicol in ophthalmic bacterial infections.

Methods: PubMed and Google Scholar databases were searched for relevant publications from the year 2000 to 2022, bordering on ophthalmic bacterial infections, chloramphenicol susceptibility profiles, and drug resistance mechanisms against chloramphenicol. A total of 53 journal publications met the inclusion criteria, with data on the antibiotic susceptibility profiles available in 44 of the reviewed studies, which were extracted and analyzed.

Results: The mean resistance rates to chloramphenicol from antibiotic susceptibility profiles varied between 0% to 74.1%, with only 6 out of 44 studies showing chloramphenicol resistance rates higher than 50%, and more than half (23) of the studies showed resistance rates lower than 20%. The majority of the reviewed publications (n=27; 61.4%) were from developed nations, compared to developing nations (n=14; 31.8%), while a fraction (n=3; 6.8%) of the studies were regional cohort studies in Europe with no country-specific drug resistance rates. No cumulative pattern of increase or decrease in ophthalmic bacterial resistance rates to chloramphenicol was observed.

Conclusion: To a large extent, chloramphenicol is still active against ophthalmic bacterial infections and is quite suitable as a topical antibiotic for ophthalmic infections. However, concerns remain about the drug becoming unsuitable in the long run due to some proof of high drug resistance rates.

Potential risks of pm2.5 and silica pollutants among communities living surround the Bosowa cement plant, Maros Indonesia 2022

Anwar Mallongi¹

¹Environmental Health Department, Faculty of Public Health, Hasanuddin University, Makassar, Indonesia

Background: This study focused on the assessment of the potential risks of PM 2.5 and silica contaminants exposures on the ecology and communities due to contaminated air inhalation and water consumption around Bosowa cement plant Maros Regency, Indonesia.

Methods: The magnitude of PM 2.5 and silica were measured during the period of April-May 2022. The level of PM 2.5 on ambient air sampling was conducted using direct reading HAZ-Dust EPAM 5000, uses a laser analyzer in order to measure particulate level matter. Then sample on air for PM2.5, and silica in water and soil data were used in the form of univariate and bivariate and multivariate analysis using chi square test. PM2.5 and silica levels were determined in samples using graphite furnace and cold vapor atomic absorption spectrometry.

Results: High concentration of PM 2.5 in ambient air were 99.13 and 87.30 µg/m3 where as the high concentration of Silica in well water were station 12 and station

10 with 13.28 and 13.23 mg/l, then in river water with 26.56 and 24.13 mg/l and on surface soil on station 10 and 11 with 159.90 and 154.88 mg/gr, respectively. The potential both ecological and human health risks posed by PM 2,5 in air and silica on all those sites environment were exceed standard and at risks for health. The total carcinogenic risks due to PM 2.5 and silica were within the non acceptable range risks for communities. The potential ecological risks of PM 2.5 and silica where the highest risks value were in surface soil with 10.15 then followed by on air particulate with 9.13 and river water 9.06, respectively. Then highest value of EWI in PM 2.5 was 0.09 and lowest was in 0.01, while the highest value Silica in well water was (0.96).

Climate vulnerability, urban health, sexual and reproductive health rights (SRHR) in Bangladesh: an explanatory analysis from Chottogram Metropolitan

Muhammad Rahaman¹, Zereen Saba²

¹Center for People & Environ (CPE), Mohammadpur, Bangladesh, ²Center for People and Environ (CPE), Dhaka, Bangladesh

There is increasing evidence that global climate change has adverse effects on human health, mainly among the poorest people in developing countries. Bangladesh is a low-lying country, and Bangladesh is considered one of the most climate-vulnerable countries in the world. As the most vulnerable climatic region in the country, Chottogram Metropolitan is increasingly experiencing climate-change-induced urban problems. For instance, occupancy by climate migrants, drainage congestion, water logging, and reduced freshwater availability are increasing concerns. This study explores the climate vulnerability, heat stress, and health disorders of urban slum dwellers of Chottogram Metropolitan. This study noted that Sexual and Reproductive Health risks of adolescents and women increased from unhygienic and overcrowded living conditions and water and sanitation problems. The slum dwellers often suffer from waterborne diseases, undernutrition and micronutrient deficiencies. Though Sexual and Reproductive Health issues are overreaching, there are no specific interventions in policy to practice level towards sexual and reproductive health rights (SRHR) considering climate vulnerability in urban slums. The study was conducted through a multidisciplinary approach and Methodology, including primary and secondary data. Secondary information was collected from reviewing policies, strategies, and action plans of GoB in terms of climate change and health services in Bangladesh. Primary information was collected through a household questionnaire survey, focus group Discussion, and key informants interview from stakeholders involved with climate-resilient health delivery services. The multi-hazard risk was analyzed using artificial intelligence in the study area. The study reveals that SRHR is far away in Bangladesh in terms of policy and practice for climate-resilient urban health delivery services in Bangladesh.

Point-of-care testing, spatial care paths, and enhanced standards of care - preparing island communities for global warming and rising oceans

Samantha Tinsay¹

¹Municipality of Bantayan, Cebu, Philippines

Background and Objective: The goal of this research is to create point-of-care (POC) strategies that accelerate decision making, increase efficiency, improve outcomes, and enhance standards of care in small-world networks (SWNs) of island communities faced with global warming, rising oceans, population migration, and public health crises. The Philippines lies in the "typhoon alley" of the Pacific and needs assessment was done in the Bantayan Archipelago to map POC testing (POCT), rescue times, and spatial care paths (SCP). Global warming is intensifying the severity of major storms, increasing their frequency, and magnifying the scope of damage. Archipelagos will be increasingly vulnerable and perpetually at risk to rising ocean levels. Every centimeter increase in ocean levels magnifies storm surges and flooding, and poor planning can adversely impact medical outcomes.

Methods: Needs assessment was done in the Bantayan Archipelago and other locales on mainland Cebu. Well-established investigational methods conducted in other limited-resource countries were adapted and there was focus on POCT, ambulance rescue, emergency medicine, critical care testing, and the organization of resources in the healthcare SWN.

Results: Significant deficiencies included lack of cardiac marker testing for rapid diagnosis of acute myocardial infarction, absence of blood gas testing for support of critically ill patients, and geographic gaps prolonging patient transfers and

delaying treatment. Strengths comprised primary care that can be facilitated by POCT, logical inter-island transfers for which decision making could be accelerated with onboard diagnostic testing, and healthcare SWNs amenable to POC advances that avoid overloading emergency rooms. Healthcare resources must be distributed to archipelago islands, not concentrated in large metropolitan areas inaccessible for emergency interventions.

Conclusions: A point-of-need focus will help improve public health, decrease disparities in mortality among rural islanders, and pave the way for heightened resilience in anticipation of the adverse impact of global warming on vulnerable coastal areas.

Health in sustainable development - barriers and drivers in implementing sustainable transport policy in Copenhagen, London, Mumbai, and Shanghai

Jack Haywood¹

¹London School of Hygiene and Tropical Medicine, United Kingdom

Background: Anthropogenic-induced greenhouse gas emissions and particulate matter exposure have health impacts both locally and globally. Sustainable transport policy formation and implementation is one way to reduce these. Several cities have sustainable transport policies, with one principle to encourage a shift from private motor vehicles to public and active transport. However, there has been little analysis examining if drivers and barriers of their uptake are acknowledged in policy.

Aim: To assess if known context-dependent barriers and drivers of active and public transport uptake are acknowledged in sustainable transport policy to enable successful implementation and thus improve human health.

Methodology: Transport policies of four cities – Copenhagen, London, Mumbai, and Shanghai – were examined for barriers/drivers of active and public transport uptake. A literature review with systematic approach was then carried out to ascertain evidence-based barriers/drivers in the same four cities. Four academic databases were searched, resulting in 30 peer-reviewed research papers being included in a thematic analysis.

Results: Five dominant themes emerged from the literature review: 1) modifiable social environment, 2) physical environment, 3) transport policy decisions, 4) transport conditions, and 5) individual factors. Cost and speed of active and public transport options were important across all cities. There were differences in focus: for example, crowding in Mumbai, and the symbolism of car-ownership in middle-income cities. The Results also made clear a 'one size fits all' approach will not work due to context-specific heterogeneity, and the gap in middle-income-based literature, particularly around active transport in Mumbai.

Conclusions: Many of the literature review-identified barriers/drivers were not acknowledged in the four city's transport policies. There were also barriers/drivers identified in policy which were not featured in the evidence-base. To ensure successful implementation of policy, context-specific evidence must inform it, with a Health in All Policies approach to ensure health benefits are gained.

A time differentiated dietary intervention effect on the biomarkers of exposure to pyrethroids and neonicotinoids pesticides

Elina Ioannou¹, Konstantinos Makris¹, Pantelis Charisiadis¹, Stavros Oikonomou¹, Nikolaos Efthymiou¹, Andria Constantinou¹, Thibaut Delplancke¹

¹Cyprus International Institute for Environmental and Public Health, Cyprus University of Technology, Limassol, Cyprus

Tailoring medical models to the right person or risk subgroups delivered at the right time is important in personalized medicine/prevention initiatives. The CIRCA-CHEM randomized 2x2 crossover pilot trial investigated whether the consumption of fruits/vegetables within a time-restricted daily window would affect biomarkers of exposure to neonicotinoids (6-chloronicotinic acid, 6-CN) and pyrethroids (3-phenoxybenzoic acid, 3-PBA) pesticides, a biomarker of oxidative damage (4-hydroxynonenal, 4-HNE) and the associated urinary NMR metabolome. A statistically significant difference ($p < 0.001$) in both creatinine-adjusted 6-CN and 3-PBA levels was observed between the two time dietary intervention windows (morning vs. evening). In the evening intervention period, pesticides biomarker levels were higher compared to baseline, whereas in the morning period, pesticide levels remained unchanged. Positive associations were observed between pesticides and 4-HNE suggesting a diurnal chrono-window of pesticide toxicity. The discovery of a chronotoxicity window associated with chrono-disrupted metabolism of food contaminants may find use in personalized

medicine initiatives.

Efficacy of activated carbon for ammonia gas reduction in selected poultry farms in Ido local government area, Ibadan Oyo state, Nigeria

Juliet Shaibu¹, Godson Ana²

¹University of Ibadan, New Nyanya, Nigeria, ²University of Ibadan, Nigeria

Background and Objectives: Ammonia gas is one of the major pollutant gases which is toxic to humans and animals when inhaled in high doses. Previous studies have demonstrated increase in ammonia emission levels among poultry farms but there is little information on ammonia gas emission reduction. Hence, this study utilized activated carbon filter in the reduction of ammonia emissions produced in selected poultry farms. Methods: The study adopted a quasi-experimental design and four poultry farms within Ibadan metropolis (renamed A, B, C and D) were purposively selected. Also, a fabricated glass chamber was used to monitor ammonia gas emission and reduction levels in the farm. Measurements of ammonia levels was carried-out six days in a week, three times daily for two weeks. at specific periods of the day with a total sampling period of eight weeks. Activated carbon produced from coconut shells and palm kernel shells was used as ammonia absorbent. Data were analysed using descriptive statistics, T-test and ANOVA at 5% level of significance.

Results: The ammonia emissions (ppm); 1150.67, 953.67, 1068.06, and 859.3 for farms A, B, C and D, respectively were higher than the guideline limits for ammonia gas by NIOSH (25ppm) and OSHA (50ppm). Coconut shells-based activated carbon had a higher absorbency capacity with the average ammonia level reduced from 36.15±30.48 at baseline to 16.38±17.71 at post-treatment level and a percentage reduction of 19.77% while Palm Kernel shells-based activated carbon had 35.80±31.15 at baseline and 18.54±16.85 at post-treatment level, with a percentage reduction of 17.26% across all the poultry farms.

Conclusions: The study showed that activated carbon obtained from coconut shells had a greater absorbency potential for ammonia gas reduction when compared to palm kernel shells activated carbon. Therefore, poultry managers should include activated carbon filters as a mechanism to reduce ammonia levels in poultry farms.

Energy conservation practices among undergraduate students of King Faisal University

Hussain Alradhi¹, Ahmed Abbas¹, Mohammed Alabadi¹, Edric Estrella¹

¹Public Health Department, College of Applied Medical Sciences, King Faisal University, Saudi Arabia

Background: Energy is very crucial component in the entire process of growth, development, and survival for any country. However, there has been a wide gap between its demand and supply. With the problem of scarcity, conservation efforts should be undertaken by every citizen of every nation. Objectives: The study is conducted with the aim of assessing the knowledge, attitudes, and practices related to energy conservation among undergraduate students at King Faisal University.

Methods: This analytical, cross-sectional study utilized data from 806 students selected through two-stage sampling procedures. Data was collected using online, self-administered questionnaire consisting of 25 items related to knowledge, attitudes, and practices on energy conservation. The proportions of students possessing high level of knowledge, exhibiting positive attitude towards energy conservation, and consistently practicing energy conservation measures were estimated using the Stata MP version 13. The crude association between the level of the knowledge and consistency of practice of energy conservation measures was determined using binary logistic regression.

Results: About 59.30% of the students (95% CI: 55.87, 62.65) had high level of knowledge related to energy conservation. Roughly 57% of the students (95% CI: 53.99, 60.80) possessed positive attitude toward energy conservation while 47.14% of them were consistently practicing energy conservation measures. Students who had high level of knowledge related to energy conservation were 1.38 times more likely to consistently practice energy conservation measures compared with those who possessed low level of knowledge.

Conclusions: The level of knowledge of King Faisal University students was significantly associated with their practices related to energy conservation. However, a large proportion of King Faisal University students were not consistent in practicing energy conservation measures.

Conceptualisations of public trust in climate science: a systematic meta-narrative literature reviewLoni Ledderer¹, Antoinette Fage-Butler², Kristian Nielsen³¹Department of Public Health, Aarhus University, Aarhus, Denmark, ²School of Communication and Culture, Aarhus University, Denmark, ³Aarhus University, Aarhus, Denmark

Background: Reflecting the connections between public health and the climate, the World Health Organization recently launched a global knowledge platform dedicated to health and climate to bring together knowledge from practitioners and scientists from various disciplines. Trust mediates the relationship between the public and scientists. There have been concerns that trust in climate science has been negatively impacted over the years by populist denials of climate change, media misrepresentations and misinformation. Public trust in climate science is deemed necessary for ensuring that the public accept and adopt climate-friendly programs and policies. As various conceptualizations of trust may be associated with disciplinary fields, our aim was to investigate how various disciplines have conceptualized public trust in climate science.

Methods: We used Greenhalgh and colleagues' systematic meta-narrative review methodology to investigate narratives of trust in climate science. A literature search identified peer-reviewed papers on trust relating to climate science in the databases Scopus, Web of Science, EBSCO, ProQuest and Ovid MEDLINE. The search resulted in 404 papers, 58 of which were included in the final sample. The following categories were used to systematize data from the papers: author(s), location of empirical studies, academic discipline, research aim, method, conceptualization of trust, type of trust and main findings.

Results: We identified 10 different academic disciplines in the sample. Most papers used quantitative Methods, were conducted in the United States and did not explicitly define trust. However, based on the papers' context and operationalization of trust, we identified six main conceptualizations of trust: attitudinal trust, cognitive trust, affective trust, contingencies of trust, contextual trust, and communicated trust.

Conclusions: Public trust was often characterized as residing in experts or expert institutions, and as being associated with trustworthy information. Public trust in health and climate experts seems crucial for affecting the conditions for health around the world.

Community knowledge, practices, and perceptions regarding environmental determinants of health in Melusi, Pretoria, South AfricaSean Patrick¹, Joyce Shirinde², Oliver Mhazo³¹School of Health Systems and Public Health, University of Pretoria, South Africa, ²School of Health Systems and Public Health, Faculty of Health Sciences, University of Pretoria, Gezina, South Africa, ³University of Pretoria, South Africa

Background: In order to improve public health policies and services, construct an environmentally resilient health sector, and promote healthy and sustainable communities, extensive study is required. Objectives: This study aimed to determine the Melusi community's knowledge, perceptions, and practices regarding environmental determinants of health and their understanding and contribution to community health and welfare. **Methods:** This cross-sectional survey was done in the Melusi informal settlement, Daspoort neighborhood in the Western suburbs of Pretoria. Using random sampling, 448 persons were interviewed using a structured electronic questionnaire.

Results: Over 60% of respondents were aware of various forms of pollution (water, land, and air). Newspapers, radio, and television, as well as the internet and health care workers, were the primary sources of information. Almost 90% of respondents said water was easily accessible. Predictors of water pollution were occupation, income, dwelling, toilet, water source and cooking source. Water source, gas and paraffin as cooking sources were the predictors of air pollution. Determinants of land pollution were pit latrine as a type of toilet, water source (JoJo tank), cooking source (paraffin) and country of birth. Lastly, occupation (unemployed), water source, cooking source and place of birth.

Conclusions: This study found a variety of patterns of knowledge, attitudes, and actions regarding environmental health determinants and the risks they bring to communities. There is more work to be done to promote awareness of pollution and climate change, as well as their impact in South African communities like Melusi.

DOI: 10.18332/popmed/165083

Occurrence of cardiopulmonary diseases after the Susa Valley wildfires of 2017Mattia Russo¹, Aldo Rosano², Chiara Cadeddu¹, Alessio Perilli¹, Luca Regazzi¹, Davide Ascoli³, Davide Vecchio³¹Italian Institute for Planetary Health, Università Cattolica del Sacro Cuore, Italy, ²National Institute for Public Policies Analysis (INAPP), Italy, ³Dipartimento di Scienze Agrarie, Forestali e Alimentari (DISAFA), Università di Torino, Italy

Background and Objective: Cardiovascular and respiratory diseases are among the leading causes of death in Italy. There is currently growing evidence of the association between exposure to fire smoke and the occurrence of cardiopulmonary diseases. According to the 2017 ARPA Piedmont (regional environmental protection agency) report, October was the hottest month in the last 60 years in the area of interest, causing fires and wildfires scattered throughout the Alpine region. These events caused continuous exposure to organic combustion products for 20 days, in the municipalities of Piedmont. This study Aims to assess the cardiovascular and respiratory risk of populations exposed to smoke from the October 2017 forest fires in the Susa Valley.

Methods: Hospital Discharge Records were requested to collect outcome data of hospitalizations and emergency department admissions for cardiopulmonary diseases that occurred before and after the fires and demographic data provided by the National Institute of Statistics regarding the resident population. Through air monitoring data from the ARPA Piedmont agency, municipalities will be grouped into 5 clusters by exposure risk, of which one will serve as a control. The assessment will be carried out from October 5th 2017 at 6 and 12 month follow-ups in the most affected areas, while the selected control period is from October 5, 2015 to October 4, 2017.

Results: The currently available international literature shows an increase in hospital admissions for cardiopulmonary conditions, including AMI, stroke, heart failure, arrhythmias, COPD, asthma attacks, and pneumonia, in the fire exposure period compared with the control period. No Italian scientific studies, other than descriptive studies from grey literature, are available. Clear and sustained increases in PM10 were found during the exposure periods by ARPA agency.

Conclusions: Our study is currently in progress, final results will be available in April 2023.

Popul. Med. 2023;5(Supplement):A159

Nine-year exposure to residential greenness and the risk of metabolic syndrome among Luxembourgish adults: a longitudinal analysis of the ORISCAV-LUX cohort studyMarion Tharrey¹, Olivier Klein², Torsten Bohn³, Laurent Malisoux³, Camille Perchoux²¹Department of Urban Development and Mobility, Luxembourg Institute of Socio-Economic Research, Esch-sur-Alzette, Luxembourg, ²Luxembourg Institute of Socio-Economic Research, Luxembourg, ³Luxembourg Institute of Health, Luxembourg

Background and Objective: A growing body of research shows a beneficial effect of exposure to green spaces on cardiometabolic health, although the evidence is limited by the cross-sectional design of most studies. This study Aims at examining the long-term associations of residential greenness exposure with metabolic syndrome (MetS) and MetS components, in Luxembourg.

Methods: We used data of 395 adults participating in both waves of the population-based ORISCAV-LUX study (Wave 1: 2007-2009, Wave 2: 2016-2017), who had no MetS at baseline. Exposure to total greenness and tree coverage were calculated for each residential address based on satellite derived Soil Adjusted Vegetation Index (SAVI) and Tree Cover Density (TCD) indices. Within- between-effect logistic and linear models were fitted to estimate both within- and between-subject variation of residential greenness on MetS and MetS components (waist circumference, triglycerides, HDL-cholesterol, fasting plasma glucose, blood pressure), respectively. Models were adjusted for several individual and neighbourhood-level confounders and for neighbourhood self-selection.

Results: A 10% within-person increase in the residential TCD over a 9-year period was associated with a 74% decrease in the odds of developing MetS and better lipid profiles (β HDL-c=2.32, 95% CI : 1.08, 3.55; β triglycerides= -6.46, 95% CI : -11.85, -1.07). Higher between-subject exposure to SAVI and TCD was associated with lower fasting plasma glucose (β : -1.22, 95% CI: -2.1, -0.35), and higher waist circumference (β : 1.08, 95% CI: 0.13, 2.02), respectively. Effect modification by sex and neighbourhood socioeconomic status were observed for triglyceride and fasting plasma glucose levels.

Conclusions: This study provides new evidence that residential greenness may play a role in preventing MetS. Based on our results, we advocate for urban greening policies and programs that promote greater density of tree cover to generate additional cardiometabolic health benefits.

Effect of exposure to quarry dust on the lung function of exposed communities in Edo State, Nigeria

Efe Edeawe¹, Steve Abah², Alphonsus Aigbiremolen³

¹Institute for Collective Health, Irrua Specialist Teaching Hospital, Nigeria, ²Department of Community Medicine, Federal University of Health Sciences, Otuokpo, Nigeria, ³Department of Community Medicine, Irrua Specialist Teaching Hospital, Irrua, Edo State, Nigeria

Background and Objectives: The health effects of quarry dust on persons living in close proximity to quarries are a public health concern. The impact of community exposure to quarry dust is largely unknown in developing countries. This study assessed exposure to quarry dust and lung function in host communities in Edo State.

Methods: A cross-sectional design was used to study 320 residents of two host communities using multi-stage sampling technique. Each community was divided into three risk zones (RZs) based on the relative distances of the residential houses from the quarry site, RZ1 being the most proximal. A semi-structured questionnaire, portable dust metre and spirometer were used for data collection. Analysis of variance was used to compare mean values.

Results: Mean indoor total suspended particulates (TSP) ranged from 139.7+81.7 in RZ1 to 130.1+79.8 (µg/m³) in RZ3 whereas mean outdoor TSP ranged from 112.8+37.8 in RZ1 to 87.3+18.5 (µg/m³) in RZ3. Forced expiratory volume in one second ranged from 71.0 + 18.2% in RZ1 to 82.9 + 113.2% in RZ3. The differences in the above parameters were statistically significant. Residents in RZ1 were most likely to have an abnormal lung function with a risk of 58% compared to those in RZ2 (36%) and RZ3 (26%).

Conclusions: The indoor and outdoor levels of particulate matter were mostly higher than permissible limits and the risk of abnormal lung function diminished with increasing distance from the quarry. Protective measures for quarry host communities are recommended.

Keywords: quarry dust, host community, lung function

Analysis of the epidemiological profile of dengue cases in the Municipality of Araras between 2010 and 2021

Amarylis Gardin¹, Lisie Justo¹

¹Faculdade São Leopoldo Mandic Araras, Brazil

Background: Dengue is an arbovirolosis, caused by infection of a virus of the genus *Flavivirus*, which is transmitted by females of two species of mosquitoes *Aedes aegypti* or *Aedes albopictus*, the latter less common in the national territory. It is noted that dengue is prevalent in the Brazilian territory, being endemic in the city of Araras. **Objective:** To trace the epidemiological profile of dengue in the municipality of Araras/São Paulo/Brazil between 2010 and 2021. **Methodology:** This is a cross-sectional, quantitative, retrospective, descriptive study based on public domain data extracted from the Notification Aggravation Information System (SINAN) linked to the Department of Informatics of the Single Health System (DATASUS). The cases were selected by the IDAGRAVO with the CID10 A90 (dengue), excluding other aggravations. The period covered was between 2010 and 2021 in the municipality of Araras, interior of the State of São Paulo/Brazil results: In the period studied, 12,006 cases of dengue were reported, the majority being female (55.7%), of white race (82.3%), with full middle education (32.37%). The majority of cases were of classical dengue (42.1%) diagnosed by clinical-epidemiological method evolving to cure (97.6%), and the most prevalent serotype is Dengue 1 (DENV 1) with notification of only 0.1%, most cases are still unknown. **Conclusions:** It is noted that dengue is still prevalent in the municipality of Araras, the subnotification and incorrect completion of the notification form present a challenge to the fight and characterization of the disease.

Modelling the future risk of Japanese encephalitis in Victoria using Geographic Information System

Mariel Lima¹, Monique Marais¹, Jacquie Cotton², Victor Sposito¹, Robert Faggian¹

¹Centre for Regional and Rural Futures, Faculty of Science, Engineering and

Built Environment, Deakin University, Australia, ²National Centre for Farmer Health, School of Medicine, Deakin University, Australia

Climate changes effect on zoonotic disease risks is not yet well understood. Japanese Encephalitis (JE) is a viral zoonotic disease endemic in Southeast Asia and the Western Pacific. The spread and transmission are associated with rain, warm temperatures, migratory waterbirds, the presence of pigs as amplifying hosts and a competent vector. In 2022, the virus reached the Australian mainland in an unprecedented outbreak spanning the eastern seaboard. This project aims to accurately identify future high-risk areas for JE transmission in a changing climate and use that information to inform preparedness policy at a state and regional level. A newly developed model, deployed in a geographical information system (GIS), was used to analyse the suitability of the state of Victoria, Australia, for the JE vector *Culex annulirostris*. The parameters considered included rain, temperature, elevation, and the distance to water bodies and piggeries. Future climate projections included in the model were generated using the global climate model ACCESS-CM2, driven by worst- and best-case scenarios SSP126 and SSP585. Monthly risk maps were generated for the current and projected climate in the years 2040 and 2060. The results showed that changes in climate expected for the state of Victoria will indeed influence the risk of JE since the areas suitable for the presence of *Culex annulirostris* will expand. Data on the location of piggeries and water bodies combined with the climate projections allowed us to identify with higher precision local areas where JE has a higher likelihood of becoming endemic. When overlaid with regional jurisdictional boundaries, the analysis also identified regional/provincial governments that need to improve their infectious disease preparedness policies. In Conclusions, climate change will create conditions in Victoria that could help JE to become endemic, indicating the need for greater preparedness.

A systematic review of evidence on the association between high temperatures, heatwaves and heat-related illnesses

Clare Faurie¹

¹School of Public Health, University of Adelaide, Adelaide, Australia

A large body of scientific evidence has established the impact of increased temperatures on human health. This study aimed to collate the research findings on the effects of extreme heat on direct heat illness (heat illnesses such as heat stroke or heat exhaustion, or dehydration) in a systematic review and meta-analysis and to provide evidence for needed public health intervention. We conducted a search of peer-reviewed articles in three electronic databases, from database inception until January 2022. A random-effects meta-analysis model was used to calculate the pooled relative risks (RRs) of the association between high temperature and direct heat-related outcomes. A narrative synthesis was also performed for studies analysing heatwave effects. Assessment of evidence was performed in three parts: individual study risk of bias; quality of evidence across studies; and overall strength of evidence. A total of 62 studies meeting the eligibility criteria were included in the review, of which 29 were qualified to be included in the meta-analysis. The pooled results showed that for every 1°C increase in temperature, direct heat illness morbidity and mortality increased by 18% (RR 1.18, 95%CI: 1.16-1.19) and 35% (RR 1.35, 95%CI: 1.29-1.41), respectively. For morbidity, the greatest increase was for heat illness (RR 1.45, 95%CI: 1.38-1.53), compared to dehydration (RR 1.02, 95%CI: 1.02-1.03). Heatwave studies also provided strong evidence of increase morbidity and mortality from direct heat illness during heatwaves. We conclude that increased temperature leads to higher burden of disease from direct heat illness. Preventative efforts should be made to reduce direct heat illness during hot weather, targeting on the most vulnerable populations. This is especially important in the context of climate change.

Is it time to set skin cancer prevention targets globally?

Monika Janda¹, Rachel Neale², Jodie Antrobus³, Sheleigh Lawler⁴, on Queensland⁵

¹Centre for Health Services Research, Faculty of Medicine, The University of Queensland, Australia, ²QIMR Berghofer, Australia, ³Queensland Health, Australia, ⁴The University of Queensland, Australia, ⁵Skin Cancer Prevention Queensland, Australia

Background and Objective: Australia has the highest incidence rate of skin cancer in the world. Skin cancer accounts for around 80% of all newly diagnosed cancers, and two in three Australians will be diagnosed before the age of 70. Skin cancer is Australia's most expensive cancer (costing \$1.7 billion annually). Within Australia, the incidence is highest in Queensland, where it is 37% higher than the national

average. Methods: Stakeholders from government, academic, patient advocacy, sports, outdoor workplaces, health and safety, and other settings co-designed skin cancer prevention targets for Queensland. They reviewed the evidence on trends in sun protection and sunburns, successful prevention programs, attitudes towards sun protection, and adoption of sun protective behaviours. They reflected on policy and/or program gaps, overall and for priority populations and settings. Results: In 2020, 49% of adults and 45% of children reported being sunburnt in the previous 12 months. Only 40% of adults used broad-brimmed hats. And fewer than 60% of adults and 80% of children applied SPF 30+ sunscreen when outdoors in summer. Additionally, sunscreen market data suggested that, on average, Australians use only 200 ml of sunscreen per person per year. Randomised trials show that sunscreen reduces sunburn, skin cancer and naevi. Models suggest that optimal sunscreen use could reduce skin cancer rates by a maximum of 30% by 2031. Based on the evidence, realistic (but ambitious) targets for reductions in melanoma and keratinocyte cancer were designed: 5% by 2030, and 25% by 2050. Conclusions: Setting targets for skin cancer reduction is important to drive policy and motivate the population to adjust their sun protection behaviour. To our knowledge, these targets are amongst the first to be set globally and could inspire other countries to follow.

DOI: 10.18332/popmed/165413

Differential impact of life course exposure to PM2.5 species and contributing emission sources on children health in India

Ekta Chaudhary¹, Franciosalgeo G.², Sagnik Dey³, Santu Ghosh²

¹Indian Institute of Technology Delhi (IIT Delhi), Delhi India, ²St. Johns Medical College, India, ³IIT Delhi, India

Exposure to air pollution affects the health of people of all age groups around the world, especially children of age under five (U5) years. PM2.5 exposure is a persistent problem in Low Middle-Income Countries (LMICs). The overall anemia prevalence among children (U5) across India is 58%. Ambient PM2.5 exposure has been identified as a potential risk factor for child low birth weight, growth failure, and mortality. Moreover, whether the impact varies with PM2.5 species is not known. Here we examine the impact of life course exposure to ambient PM2.5 components on anemia prevalence among children (U5) across 640 Indian districts. We use NFHS-4 health data, the satellite-based PM2.5 exposure from Dey et al., 2020, whereas the species and sectoral data (WRF-CMAQ model) from Singh et al., 2021. The WRF-CMAQ model dataset provides information on PM2.5 species such as nitrate (NO3), ammonium (NH4), black Carbon (BC), organic carbon (OC), sulfate, dust and various sectors. A multiple logistic regression model adjusted with potential risk factors is used to estimate the effects of PM2.5 species on anemia prevalence. At the aggregate level, for each interquartile range (IQR) of NO3, anemia prevalence increased with an odds ratio (OR) 1.26 (95% UI: 1.24,1.29). For the corresponding increase in NH4, others, BC, OC, SO4, and soil, anemia prevalence increased by OR 1.19 (95% UI: 1.17,1.21), 1.16 (95% UI: 1.14, 1.18), 1.15 (95% UI: 1.13, 1.17), 1.11 (95% UI: 1.09, 1.13), 1.12 (95% UI: 1.11,1.13), and 1.10 (95% UI: 1.08,1.11), respectively. Furthermore, for every IQR increase in PM2.5 exposures attributable to sectoral emissions, domestic sector showed the highest OR, followed by road dust, international, agricultural waste burning, industry, and transport sectors. This study will support the policymakers to trace specific sectors that are contributing to PM2.5 exposure and other pollutants that in turn, cause lethal health impacts.

How can health evidence be packaged to reach actors across a complex system to influence the development of healthy urban environments?

Geoff Bates¹, Andrew Barnfield², Charles Larkin³, Sarah Ayres²

¹Institute for Policy Research, University of Bath, Bath, United Kingdom,

²School for Policy Studies, University of Bristol, United Kingdom, ³Institute for Policy Research, University of Bath, United Kingdom

Background and Objective: The urban environment is a key determinant of non-communicable diseases and health inequalities. It is shaped by the complex system of urban development that includes stakeholders across many sectors with different priorities and needs. Consequently, health outcomes are often subordinate to other agendas or overlooked in urban policymaking. We aimed to identify the most effective approaches to package health evidence for actors across the United Kingdom's (UK) complex urban development system to put health at the forefront of decision-making.

Methods: We applied a systems perspective to examine how evidence on non-communicable diseases and health inequalities can be translated and delivered

to inform decision-making in a complex policy environment. We undertook 132 interviews exploring perceptions on how evidence can be communicated so that it lands with critical actors working to influence urban development in the UK. Participants included property developers, urban planners, real estate investors, policy experts, senior civil servants, and local government officials. Data were analysed using a mixed deductive-inductive coding approach and through thematic analysis to identify similarities and differences across stakeholder groups.

Results: Findings reveal that creating evidence-based narratives that target actors' emotions can reach actors across a complex system. Drawing on personal accounts helps to elicit an emotional response and bring health data to life for a wide range of stakeholders. Demonstrating rigour and context are important for ensuring confidence in these narratives. Our analysis indicates that while variation in preferences for data exist, they appear to be determined more by personal values and data expertise than professional sector.

Conclusions: A storytelling approach, supported by a range of data, should be considered to reach actors across a complex system with evidence on non-communicable diseases and inequalities and to bring them together to advance the creation of healthy urban environments.

Determining environmental attitudes of medical faculty students and evaluation of environmental behavior

Ezgi Yucel¹, Sevil Gedik², Feyza Muz¹, Didem Arslantas¹, Alaettin Ünsal¹

¹Department of Public Health, Faculty of Medicine, Eskisehir Osmangazi University, Türkiye, ²Eskisehir Odunpazari District Health Directorate, Eskisehir, Türkiye

Background: Environment is a concept that includes interaction between inanimate components like air, water, soil, and living creatures like human, animals. The environmental pollution due to increased and uncontrolled usage of resources, urbanization, industrialization, nuclear power plants, causes serious threats which include death and diseases. It is aimed to determine the attitudes of medical faculty students towards the environment and to evaluate their environmental behavior (EB). **Methods:** This cross-sectional study was conducted on Eskişehir Osmangazi University Faculty of Medicine students. The questionnaire prepared based on the literature was filled out online by the participants. The study group consisted of 874 students who agreed to participate in the survey. The EB scale was used to assess the level of EB. Mann-Whitney U, Kruskal Wallis, and Spearman correlation tests were used for the non-parametric analyses.

Results: The ages ranged from 17-35, with a mean of 21.62±2.14. In the study, they were found to have higher scores on the EB Scale; those who are 21 and under, women, member of preclinical classes, those who define themselves environmentally friendly, those who have attended any meeting or received education about environmental awareness and environmental health, those who separate the household waste into groups such as organic/ glass/ plastic, those who isolate the wastes that could be harmful to the environment, those who doesn't use cars for short range travels, and those who avoided the use of disposable materials. A moderate positive correlation was found between the scores of EB scale and items about environmental attitudes (r=0.616; p<0.001). **Conclusions:** In order to achieve sustainability in terms of a clean and healthy environment, one of the most important goals is to increase the awareness of university students. Therefore, in order to improve EB, it is recommended to add special lectures to increase environmental awareness in undergraduate education.

DOI: 10.18332/popmed/165449

Artificial light at night and breast cancer risk: the findings from CECILE study, France

Nirmala Prajapati¹, Adélie Boileau¹, Emilie Cordina-Duverger¹, Elodie Faure¹, Pascal Guénel¹

¹Université Paris-Saclay, UVSQ, Gustave Roussy, Exposome and Heredity Team, CESP (Center for Research in Epidemiology and Population Health), UMR 1018, Inserm, Villejuif, France

Background and Objectives: Light pollution is growing as the newest form of environmental pollution. Experimental and epidemiological studies suggested that exposure to artificial light at night (ALAN), especially to blue light, disrupts the circadian rhythm, inhibits melatonin production, and increases the risk of breast cancer. We assessed the association between exposure to outdoor ALAN and breast cancer. **Methods:** We used data from a population-based case-control study, including 1185 incident breast cancer cases and 1282 healthy controls enrolled in 2005-2007 from two French departments- Côte d'Or and Ille-et-Vilaine. Data for outdoor ALAN exposure was obtained using calibrated images from

Defense Meteorological Satellite Program (DMSP) for 1995-2006. Exposure was assessed over the 10 years prior to inclusion in the study by cross-referencing the DMSP images and the geocoded locations of residences in ArcGIS. Logistic regression was used to obtain odds ratios (OR) and 95% confidence intervals (CI) for the association, adjusting for sociodemographic, reproductive, and lifestyle-related factors, night-shift work, and urbanization.

Results: The overall OR for breast cancer per 1 standard deviation increase in ALAN exposure (129.29 nW/cm²/sr) was 1.05 (95% CI: 0.95-1.17). Subgroup analyses showed slightly higher ORs in post-menopausal women (OR: 1.15; 95% CI: 0.99-1.34) and in women who never worked at night (OR: 1.08; 95% CI: 0.96-1.22). The association was stronger for HER2-positive breast tumors (OR: 1.27; 95% CI: 0.99-1.62). Conclusions: Our study did not find an association between exposure to outdoor ALAN and breast cancer. However, possible associations between outdoor exposure to ALAN and breast cancer risk in specific subgroups were indicated. This study had several strengths, including use of calibrated satellite images for outdoor ALAN assessment and consideration of a large set of potential confounders. Further large-scale studies using improved exposure assessment methods, including measurement of blue light and exposure assessment at the individual level, are required.

Ciguatera Fish Poisoning: an economic evaluation of healthcare costs and assessment of current level of awareness among islanders and visitors in three Caribbean Islands

Alessio Perilli¹, Alisha Morsella¹, Walter Ricciardi¹, Chiara Cadeddu¹
¹Università Cattolica del Sacro Cuore, Rome, Italy

Background and Objective: Ciguatera Fish Poisoning (CFP) is the most common seafood-borne intoxication, affecting around 50000 people annually, mostly in tropical coastal areas. It is caused by toxins released by microalgae whose proliferation is promoted by ocean warming, coral bleaching and anthropogenic disturbances. Small Island Developing States are exposed to severe productivity losses and deprivation of food sources as a Results of CFP. However, they show scarce awareness, hindering appropriate preventive behavior, risk management strategies and formal case reporting. The objective of this study is to estimate CFP incidence in three Caribbean islands (Guadeloupe, Martinique, Saint Lucia), assess its economic impact in terms of health costs and productivity loss and the awareness level in both residents and tourists.

Methods: Economic data will be collected through hospital databases and supplemented with interviews with healthcare professionals and managers. Incidence will be estimated through disease notifications and survey data. Two questionnaires were designed to assess knowledge, behavior and intentions concerning CFP. A reliability analysis, and descriptive and inferential statistics will be applied to the responses.

Results: The fisherman survey comprises 57 questions regarding: respondents' general characteristics (14), CFP-related personal experiences (20), knowledge (9), behavior (11) and intentions (3). The tourist version includes 43 questions on: respondents' general characteristics (5), CFP-related personal experience (19), knowledge (9), behavior (7), intentions (3). In February – April 2023, both surveys will be administered to a convenience sample and economic data will be extracted. Preliminary results will be available in May 2023.

Conclusions: The estimated incidence is expected to differ from that available in literature due to the lack of formalized case reporting and awareness. A higher level of awareness is expected among residents rather than tourists. Findings will provide a novel contribution to research and inform policy decisions, especially considering CFP projected expansion.

How do neighborhoods influence educational achievement? Reviewing qualitative studies by employing Nussbaum's perspectives

Rita Agdal¹, Hanne Mikkelsen¹

¹Western Norway University of Applied Sciences, Norway

Background: Education is a crucial resource for life chances, with a close correlation with socioeconomic inequalities in health. Providing education for all is an essential part of health promotion. While the effects of neighborhoods on educational achievement have been well researched, studies have tended to ask simplified and unbalanced questions about the value of neighborhoods. Instead, more insightful answers could be derived from questions on understanding the complexity of neighborhoods' influence. Aims: We sought insight into the complexities of neighborhood's influence on educational achievement by reviewing

qualitative literature from Nordic countries emphasizing urban neighborhoods' influence on educational achievement. We also applied perspectives from Nussbaum's capability approach to address these complexities. Methods: This critical systematic qualitative review included studies on the influence of neighborhoods on academic success generated from nine databases using a search string. Two reviewers selected the studies following the preferred reporting items for systematic reviews and meta-analyses (PRISMA) flowchart and inclusion criteria through a blinded process. Out of 7009 extracted records, 17 peer-reviewed articles were examined. We evaluated the scientific quality of the study using EPICURE.

Results: Findings showed three main themes: social support from neighborhood agents, the role of attachment and the reputation of the place, and how policies influence everyday life and educational achievement. The articles were descriptive and built on perspectives regarding social reproduction and social capital. Conclusions: Integrating perspectives from the capability approach to discuss the complexities of neighborhoods' influence on educational achievement may facilitate a shift toward identifying possibilities in neighborhoods.

Is the community food environment in Chile associated with fruit and vegetables consumption?

Leticia Cardoso¹, Laís Botelho¹, Irene Justiniano², Amy Auchincloss³, Mariana Menezes², Maria Pina¹, Vanderlei Matos¹, Daniel Skaba¹, Lorena Garcia⁴, Tamara Herrera⁵

¹Oswaldo Cruz Foundation, Brazil, ²Federal University of Ouro Preto, Brazil,

³Drexel University, United States, ⁴Universidad Peruana Cayetano Heredia, Peru, ⁵University of Chile, Chile

Diet quality is influenced by many individual and social characteristics, as well as the community food environment. There is evidence in the literature showing associations between food environment and diet, but there is still scarce information for Chilean population. Objective: To explore the relationship between community food environment and diet quality in three Chilean cities. Methods: Food store were geocoded and diet survey data standardized from SALURBAL study were used. The food environment was evaluated by geospatial algorithm based on Google Earth data and density store indicators by different categories were estimated. The personal-level data included socioeconomic, demographic, health and nutrition variables. Diet quality was assessed by daily consumption of Fruits and Vegetables (FV) (≥ 5 servings/day). Two-level with mixed effects binary logistic regression were performed.

Results: 48410 food stores were evaluated, distributed across 2,442 neighborhoods in 51 subcities in three Chilean cities (Santiago, Valparaíso, Concepción). The population sample included 1,292 individuals, of which 84.3% had inadequate consumption of FV. We observed a higher density of ready-to-eat food stores and a low density of FV stores in these cities. Store density increased as population density quartiles and the intra-urban socio-environmental index increased. No association was identified between food environment and FV consumption. Conclusions: The food environment in the evaluated cities is dominated by stores with an unhealthy profile and low availability of FV, but there is no consistent relationship with FV consumption. Other factors may be determinants of FV consumption in this population.

The environmental health literacy of Italian general population: the SPeRA cross-sectional study

Marta Gea¹, Christian Previti¹, Fabrizio Bert^{1,2}, Gregorio Massocco¹, Giuseppina Moro¹, Giacomo Scafoli^{3,4}, Tiziana Schilirò¹, Roberta Siliquini⁵

¹Department of Public Health and Pediatrics, University of Turin, Italy,

²Health Local Unit ASL TO3, Italy, ³Department of Public Health and Pediatrics, University of Turin, ⁴Health Local Unit ASL TO3, ⁵Department of Public Health and Pediatrics, University of Turin, AOU City of Health and Science of Turin, Italy

Background and Objective: Environmental Health Literacy (EHL) includes knowledge of health effects due to environmental exposure and skills to protect health from environmental risks, so it can be a useful tool to prevent diseases. This cross-sectional study investigated for the first time some aspects related to EHL of the Italian adult population (i.e. information sources, risk perception, attitude/adoption of pro-environmental behaviours and barriers to them). Methods: Data were collected through an online questionnaire (n=672) and analysed through descriptive analyses and multivariable logistic regression models.

Results: The results showed that internet and TV were the most used information

sources and that participants with incomplete/insufficient self-perceived knowledge of health effects due to environmental risks verify less information about this topic [adjOR=0.38 (CI95% 0.25-0.59)/0.09 (0.04-0.21); $p<0.001$ / <0.001 , respectively], potentially spreading fake news. The self-perceived exposure to pollution was higher in participants living in towns than in rural areas [small, medium, big towns adjOR=2.37 (1.41-3.97), 2.10 (1.11-3.96), 3.11 (1.53-6.31); $p=0.001$, 0.022, 0.002, respectively], suggesting that pollution is more perceived in urban areas, while it was lower in participants with incomplete/insufficient knowledge about pollution health effects [adjOR=0.54 (0.32-0.92)/0.30 (0.13-0.67); $p=0.022$ /0.004], confirming that knowledge is essential to achieve awareness. Since insufficient self-perceived knowledge of pollution health effects was negatively associated with adoption of pro-environmental behaviours [adjOR=0.37 (0.15-0.90); $p=0.028$], the role of EHL as virtuous behaviour promoter was proven. Risk perception and attitude toward pro-environmental behaviours varied according to gender and education level, confirming the importance of socio-demographic characteristics for EHL related issues. Finally, lack of institutional support, lack of time and cost were identified as important barriers for many pro-environmental behaviours. Conclusions: This study provided useful data to design prevention programmes, underlined some barriers to pro-environmental behaviours and highlighted the need to promote attitudes and behaviours aimed at contrasting environmental pollution thus protecting human health.

Forecasting malaria morbidity to 2036 based on geo-climatic factors in the Democratic Republic of Congo

Ngianga-Bakwin Kandala^{1,2}, Elysee Kabongo³, Eric Panzi³

¹Department of Epidemiology and Biostatistics, Western University, London, Canada, ²Schulich School of Medicine and Dentistry, Western University, London, Canada, ³Institut Supérieur des Techniques Médicales de Kinshasa (ISTM/Kin), Kinshasa, Democratic Republic of Congo

Background and Objectives: Malaria is a global burden of morbidity and mortality. In Congo (DRC), malaria prevalence is increasing due to strong climatic variations. Reduction of malaria morbidity and mortality, the fight against climate change, good health and well-being constitute key development targets. We aim to predict malaria morbidity to 2036 based on 2001-2019 data, as a basis of an early detection of anomalies in weather patterns.

Methods: Meteorological data from Epidemiological Surveillance Directorate including all malaria cases based on positive blood test results, either by microscopy or by rapid diagnostic test, was used to estimate malaria morbidity and mortality from 2001 to 2019. Time series combining several predictive models were used to forecast malaria epidemic episodes to 2036. The impact of climatic factors on malaria morbidity was modelled using multivariate time series analysis. **Results:** Geographical distribution of malaria prevalence from 2001-2019 shows disparities between provinces with the highest of 7700 cases/100,000 people at risk for South Kivu. Malaria has been most deadly in Sankuru with a case-fatality rate of 0.526%. The stochastic trend model predicts an average annual increase of 6024.07 malaria cases with exponential growth in epidemic waves over the next 200 months of the study, an increase of 99.2%. Associated risk factors were geographic location, total evaporation under shelter, maximum daily temperature at two meters altitude and malaria morbidity.

Conclusions: The increase in new malaria cases is statistically related to population density, average number of rainy days, average wind speed, and unstable and intermediate epidemiological facies. We provide relevant information for the government to respond to malaria in real time by setting up a warning system integrating the monitoring of rainfall and temperature trends and early detection of anomalies in weather patterns.

Impacts of extreme weather events on enteric infectious disease outbreaks: evidence from New Zealand

Farnaz Pourzand¹, Simon Hales¹

¹Department of Public Health, Health Environment and Infection Research Unit, Otago University, Wellington, New Zealand

In 2016, the largest recorded water-borne outbreak of *Campylobacter* affected thousands of people in the Hawke's Bay region of New Zealand (NZ). Investigations suggested that heavy rainfall had led to contamination of the water supply with livestock faeces. Climate change is already causing changes in the frequency and/or severity of extreme weather with important implications for public health. In this study, we test the hypothesis that enteric disease outbreaks are associated with climate patterns in New Zealand. We have identified outbreaks

of acute gastrointestinal infections (AGI), based on Spatio-temporal analyses of notifications (2000 to 2019). We will estimate the relationship between AGI and weather variables (daily temperature and rainfall), accounting for modifying effects of local factors (e.g. water supply characteristics) using Poisson regression methods. We present our initial Results of the association between extreme precipitation events and campylobacteriosis in the Hawkes Bay region. Our analysis provides a more precise picture of the effect of extreme climate events on AGI outbreaks. It has a practical application as it provides inputs for evidence-based policy to minimise enteric disease risks associated with climate extremes by implementing appropriate actions such as improving water treatment in networked suppliers and climate-based early warning systems.

Microplastic-sorbed chemicals: a threat from sand and surface water

Hongrui Zhao¹, Ileana Federigi¹, Marco Verani¹, Annalaura Carducci¹

¹University of Pisa, Laboratory of Hygiene and Environmental Virology, Department of Biology, Via S. Zeno 35/39, 56127 Pisa, Italy

Background and Objective: Marine environments can be contaminated by various anthropogenic persistent organic pollutants, such as petroleum-related (e.g., polycyclic aromatic hydrocarbons, PAHs), industrial (e.g., polychlorinated biphenyl, PCBs), and agriculture-related (e.g., organochlorine pesticides, OCPs) chemicals. Moreover, microplastic (MPs, particles < 5 mm) pollution of seawater is increasing in recent years and they can behave as a vehicle of chemicals acquired from the surrounding environment. Such MPs role is relevant from a public health perspective, increasing the exposure of beachgoers to harmful chemicals. In this paper, 40 field studies of MPs-sorbed organic pollutants were reviewed with the aim to understand the level of chemical contamination of MPs in the marine compartments.

Methods: The literature search was conducted following Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines. The keywords included microplastic in combination with the organic contaminants that could be adsorbed by MPs.

Results: The methodology used for MPs-sorbed chemicals detection showed great differences among the studies, from sampling to analytical techniques. The most frequently searched chemicals were PCBs (55% of the reviewed papers) followed by PAHs (47.5%), and OCPs (42.5%). When such chemicals were searched, they were detected in almost one of the sampling sites included in each study. Overall, PCBs level showed a median concentration of 290 ng/g. The median PAH concentration was 3,595 ng/g, with an extremely high amount of 120,000 ng/g found in MPs from Chinese seawater. Dichlorodiphenyltrichloroethane was the most frequently detected OCP, with a median of 126.9 ng/g.

Conclusion: This paper revealed that MPs can accumulate high level of chemicals in the marine environment, thus increasing the human exposure during swimming or rest on the beach. Despite the public health relevance of such human exposure, this topic is still little explored as demonstrated by the lack of standardized method for MPs collection and chemical analysis.

Air pollution and oxidative stress in adults suffering from airways diseases. Insights from the gene environment interactions in respiratory diseases multi-case control study

Giulia Squillacioti¹, Valeria Bellisario¹, Alessandro Marcon², Pierpaolo Marchetti², Angelo Corsico³, Pietro Pirina⁴, Giuseppe Verlato², Roberto Bono¹

¹University of Turin, Italy, ²University of Verona, Italy, ³University of Pavia, Italy, ⁴University of Sassari, Italy

Background and Objective: Air pollution is a leading cause of global mortality and morbidity. Oxidative stress is considered a key mechanism underlying air pollution-mediated health effects, especially in the pathogenesis/exacerbation of airways impairments. However, little evidence is available on subgroups at higher risk of developing more severe outcomes. This multi-center study aims to evaluate the association between air pollution and oxidative stress in healthy adults and patients affected by different airways diseases from the Italian GEIRD (Gene Environment Interactions in Respiratory Diseases) multi-case control study. **Methods:** Current analyses include 1841 adults (49% females, 20-83 years) from four Italian centers: Pavia, Sassari, Turin, and Verona. Following a 2-stage screening process, cases of asthma (n=578), chronic bronchitis (n=23), rhinitis (618), or COPD (n=54) and controls (n=568) were identified. Systemic oxidative stress was quantified by measuring urinary 8-isoprostane and 8-OH-dG. Individual exposures to NO₂, PM₁₀, PM_{2.5}, and O₃ were derived at residential level during

2013-2015. We investigated the association between oxidative stress biomarkers and air pollution tertiles using multilevel multivariable regression models adjusted by age, BMI, smoking habits, education level and season of sample collection, with centers as random intercept.

Results: The geometric means (ng/mg creatinine) of 8-isoprostane and 8-OH-dG were 0.7 (95%CI:0.68-0.76) and 3.8 (95%CI:3.6-4.0), respectively. Only cases exhibited higher levels of log-transformed 8-isoprostane and 8-OH-dG in association with NO₂ (0.22 95%CI:0.00-0.45 and 0.20 95%CI: 0.03-0.37), PM₁₀ (0.34 95%CI: 0.12-0.55 and 0.21 95%CI: 0.05-0.37) and PM_{2.5} (0.27 95%CI: 0.05-0.49 and 0.18 95%CI: 0.02-0.34) compared to the first tertile of exposure (NO₂:5-26µg/m³, PM₁₀: 11-33µg/m³, PM_{2.5}: 8-24µg/m³). No association was observed for O₃.

Conclusion: Our findings suggest that exposure to air pollution may increase systemic oxidative stress levels in people suffering from airways diseases. Effective prevention strategies should consider early biological effects observed in susceptible people, whom additional risk level might be currently underrated.

DOI: 10.18332/popmed/163764

Risk analysis for the human health derived from sewage management: perspectives for the reuse

Ileana Federigi¹, Marco Verani¹, Roberto Salvadori², Simone Lippi², Annalaura Carducci¹

¹Laboratory of Hygiene and Environmental Virology, Department of Biology, University of Pisa, Italy, ²Acque S.p.A., Italy

Background and Objectives: In a changing scenario characterized by extreme weather events and water shortages, a paradigm shift is occurring on wastewaters: from waste to water resource. Europe is moving in that direction through the releasing of a regulation for water reuse in crops irrigation (EU 2020/741) and a profound revision, reuse-oriented, of legislative framework on wastewater management started during 2022. The implementation of reuse practices increases the possibility of human exposure to biological and chemical agents, that needs to be carefully evaluated in a public health perspective. This is the aim of a project funded by the National Operational Programme (NOP) on research and innovation (European Social Fund).

Methods: The project involves a university and a sewerage company in a collaborative effort for the selection of wastewater treatment plants (WWTPs) for reuse purposes. A water safety plan (WSP) is developed using both microbiological and physicochemical data from private repositories and field data obtained from dedicated monitoring campaigns, searching for fecal indicators (Escherichia coli, enterococci, bacteriophages) and human pathogens, namely Salmonella spp. and enteric and respiratory viruses (adenovirus, norovirus, enterovirus, coronaviruses). The health risk is assessed through the Quantitative Microbial Risk Assessment (QMRA) framework.

Results: In the first phase of the project, two WWTPs has been selected for agricultural and urban reuses. Repository data will be analyzed searching for a chemical proxy for microbial load, whose real-time monitoring allows the application of timely control actions along the sewage treatment (e.g., disinfection process).

Conclusion: The reuse processes are needed for a sustainable development and for adapting to climate change. Wastewater management plays a key role for a safety reuse, limiting health risks. Therefore, there is an urgent need for the application of WSP to sewage treatment in combination with the assessment of human health risks attributable to water reuse.

DOI: 10.18332/popmed/163765

Mortality and hospitalization in Italian contaminated sites of national concern for remediation: the global evaluation

Lucia Fazzo¹, Fabrizio Minichilli², Valerio Manno³, Ivano Iavarone¹, Marta Benedetti⁴, Paolo Contiero⁵, Alice Maraschini³, Giada Minelli³, Roberto Pasetto¹, Paolo Ricci⁶, Amerigo Zona¹

¹Italian national Institute for Health - Istituto Superiore di Sanità, Dept of Environment and Health, Istituto Superiore di Sanità, Italy, ²National Research Council, ³Italian national Institute for Health - Istituto Superiore di Sanità, Statistical Service, Istituto Superiore di Sanità, Italy, ⁴Italian national Institute for Health - Istituto Superiore di Sanità, ⁵Fondazione IRCCS Istituto Nazionale dei Tumori, Environmental Epidemiology Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Italy, ⁶Agenzia di Tutela della Salute della Val Padana, Unit of Epidemiology, Agenzia di Tutela della Salute della Val Padana, Italy

Backgrounds and Objective: In Italy, an epidemiological surveillance of the

populations living in the 46 contaminated sites of national concern for remediation (CSs) has been underway, since 2011 (SENTIERI Project). CSs are defined of national concern for their contamination due to the presence of pollution sources, such as chemical industries, petrochemical plants and refineries, landfills. We aimed at estimating the global mortality (2013-2017) and hospitalization (2014-2018) among the populations living in the 46 CSs (316 municipalities; 6,227,531 inhabitants).

Methods: The excess deaths (observed-expected) for the main groups of diseases were calculated for the 46 sites combined. A random effects meta-analysis of the Standardized Mortality and Hospitalization Ratios (SMR/SHR) of each CS was performed for all the sites and their groupings, based on the typology of pollution sources. 90% Confidence Intervals and I² value complemented SMR/SHR pooled value. The analyses were performed in general population and age-subgroups.

Results: In the 46 sites, 8,342 exceeding deaths (1,668/year) were estimated, 4,353 in males and 3,989 in females. Pooled SMR and SHR for all causes exceeded in both genders: males: SMRpooled=1.02 (90%CI:1.00-1.04); SHRpooled=1.03 (90%CI:1.01-1.04); females: SMRpooled=1.02 (90%CI:1.00-1.04), SHRpooled=1.03 (90%CI:1.01-1.05). These excesses are mainly attributable to malignant tumours. In subgroups of sites, exceeding SMRs were observed for all malignant mesotheliomas (MM) and pleural MM, lung and colorectal cancers in both genders. SHRs for all causes were in excess in the first year of life (males: SHRpooled=1.08, 90%CI:1.03-1.13; females: SHRpooled= 1.08, 90%CI:1.03-1.14); the hospitalization for all causes exceeded also in 0-19 and 20-29 groups (+3-5%); no excesses of mortality were observed in 0-29 years age-classes.

Conclusion: The results suggest that living in CSs is a risk factor for cause-specific mortality and hospitalization, even if the ecological approach and the mixtures of environmental exposures sources do not allow conclusions on specific etiological hypothesis.

Popul. Med. 2023;5(Supplement):A179

DOI: 10.18332/popmed/163773

What is the carbon footprint of food waste? results from an analysis in a hospital canteen in northeast Italy

Peter Cautero¹, Daniela Zago¹, Diana Menis¹, Federica Fiori¹, Lucia Lesa², Alessandro Conte³, Maria Parpinel¹, Laura Brunelli⁴

¹University of Udine, Department of Medicine, University of Udine, Udine, Italy, ²Azienda Sanitaria Universitaria Friuli Centrale, ³Azienda Sanitaria Universitaria Friuli Centrale, Medical Directorate, Hospital "Santa Maria della Misericordia" of Udine, Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy, ⁴University of Udine; Azienda Sanitaria Universitaria Friuli Centrale, Department of Medicine, University of Udine, Udine; Accreditation, Quality and Clinical Risk Unit, Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy

Background and Objective: Attention to economically and environmentally sustainable development has increased in recent years. Fundamental, in pursuing these goals, is attention to reducing food waste, which accounts for about one third of global production. The aim of this study was to evaluate the food waste generated by consumers in a hospital canteen in Italy.

Methods: We analyzed the meals of workers who accessed a northeastern Italian hospital canteen. We photographed trays before and after the consumption for five days in September 2022. We used a modified Comstock visual scale to estimate remaining food, and we estimated the carbon (CF) and water footprints (WF) of food waste using Barilla's SU-EATABLE LIFE database.

Results: We took before and after meal photos of 240 meals. A total of 188 meals (78%) were completely consumed, while 52 of them had waste left over. Food waste accounted for 2% of the total foods served. The average food waste per tray of leftovers was 10% and consisted mainly of salad. On average, 14 g CO₂eq./tray (CF) and 15 LH₂O/tray (WF) were generated by the wasted portion of the meal. The median value was 0(0-0) for both CF and WF. A total of 3.3 kg CO₂eq. was generated for the production of discarded foods, which is approximately equivalent to a 16.5 km car trip.

Conclusion: This study was able to establish that, despite the virtuous behavior of most of the consumers, waste in the observed hospital canteen was limited but not negligible. The degree of personalization of the portions offered by the canteen staff in addition to the standard portion could justify the small amount of food waste. In the future, it would be interesting to consider not only the waste generated by users, but also that one generated during preparation and serving.

DOI: 10.18332/popmed/163872

Different approaches to research on urban health: a meta-narrative review

Evelyn de Leeuw¹, Jinhee Kim¹, Ben Harris-Roxas¹, Peter Sainsbury²

¹University of New South Wales, Australia, ²University of Notre Dame, Australia

Background and Objectives: Urban health is a multi-disciplinary field of research and practice, and participants address urban health based on different ontological beliefs. Identifying and articulating the different approaches is integral for transdisciplinary research and practice. This meta-narrative review identifies which epistemic traditions have considered the broad topic of urban health. This review further aims to identify the cross-cutting themes that appear across the epistemic traditions.

Methods: In this meta-narrative review, we use bibliometric analysis as a guide to identify the different approaches that appear in the scientific literature on urban health. A search in Web of Science Core Collection retrieved 5,926 publications. Bibliometric network analyses of co-citation relationships produced clusters of closely related authors and publications. The highest co-cited publications in each cluster were selected and analysed against conceptual, theoretical, methodological and instrumental parameters.

Results: The document co-citation network analysis showed clustering of urban health research activities into five clusters: sustainable urban development, urban ecology, urban resilience, public health and urban planning, and urban green spaces and health. Each cluster has a different approach to the urban health concept. Meanwhile, several cross-cutting themes were found in the methodological and instrumental across all five clusters.

Conclusion: Urban health research topics extend beyond the traditional public health and the urban planning centred view. The cross-cutting themes that emerge across all topic areas underpin the paradigmatic differences that require even further efforts for collaboration than the disciplinary differences that require even further efforts for collaboration than the disciplinary differences. For urban health researchers to actively collaborate across diverse disciplines and research traditions, understanding which approaches exist and how these approaches are different and similar is critical. Such endeavours are required to produce the transdisciplinary knowledge for transforming policy.

DOI: 10.18332/popmed/163892

Adaptation planning for climate change: is the health and safety of rural women a priority for local government? a policy analysis

Elena Wilson¹, Karen Anderson¹

¹La Trobe University, Australia

Background and Objective: Recent fires and floods in rural Australia attest to public health challenges of climate change leaving many already vulnerable rural communities in turmoil. Growing evidence that gendered health impacts and increased risk of violence against women are characteristic of the aftermath of disasters is a health equity and justice concern.

The Victorian government in Australia mandates the development of climate change adaptation plans and health and wellbeing plans at local government level. Plans must consider health implications of climate change for each municipality in addition to proposing actions for preventing and responding to family violence, promoting gender equality and conducting gender impact assessments.

The aim of this study was to explore how rural municipalities in Victoria recognise and prioritise women's health and safety in relevant municipal plans.

Method: Municipal documents and websites, (191), were accessed for all 48 rural Victorian municipalities. Those which explicitly mentioned climate change and gender or women were included for analysis. Twelve documents (6%) from 11 municipalities met the selection criteria. A content analysis identified any recognition of health impacts on women and proposed adaptation strategies.

Results: Eight documents from seven municipalities, demonstrated minimal recognition of health impacts on women arising from climate change. This superficial recognition from a small proportion (15%) of rural municipalities lacked any explanation or actions to mitigate the impacts. Two documents mentioned vague adaptation strategies.

Conclusion: Women's health and safety was poorly recognised in the context of climate change suggesting that it has not been a high priority. The lack of a sense of urgency and commitment to adaptation planning is problematic and requires urgent action so that vulnerability of rural women is not exacerbated by disaster. Further research is needed to explore attitudes and capacity for adaptation planning in rural municipalities.

Popul. Med. 2023;5(Supplement):A182

DOI: 10.18332/popmed/163894

Global, local and individual context of climate change: what do medical faculty students think? A qualitative assessment

Merve Akbayrak¹, Isil Ergin¹

¹Ege University Faculty of Medicine, Department of Public Health, Bornova/İZMİR 35100", Turkey

Background and Objective: Societies that are aware of the global, local and individual context of climate change can succeed to develop appropriate social, economic and environmental strategies. This qualitative research aimed to determine the opinions of future doctors on; the effects of climate change at global, local and individual levels; the role of industry, states and individuals; awareness raising activities and training options.

Methods: Nine focus group interviews were conducted between August-October 2022 among Ege University internship students(n=65). Semi-structured interviews within a framework of five sections (1.definition of climate change-general impact, 2.role of industry, 3.role of states, 4.role of individuals, 5.training suggestions) lasted 43±11 minutes. Ethics Committee approval, consent of the participants were obtained. Records and observation notes were transcribed into written form. By content analysis, emergent themes were obtained. No financial support or conflict of interest existed.

Results: Of the participants %32 were women, %38 had rural roots and only 3 attended structured training for climate change. Three leading themes of the five sections were; 1.global warming, drought, impact on agriculture, 2.industry carbon emissions, avoiding responsibility, sustainable technologies, 3.inadequacy of inspections, necessity of sanctions, enabling/disabling preventive practices, 4.reducing water consumption, economic crisis invading the agenda, absence of environmental regulations as a barrier, 5.preschool/primary school education, visual tools in training, continuing education at all ages.

Conclusion: The knowledge and individual awareness of future doctors about climate change, its impact at different levels and the roles of different actors were detected to be sufficient yet their motivation to take role and interfere were lacking. Individual agendas invaded by economic crisis and personal needs were in competition with their interest on climate change even for those who were eager to take role. Lack of public solutions lead by local authorities prevents those who are eager to pay individual efforts.

Popul. Med. 2023;5(Supplement):A183

DOI: 10.18332/popmed/163972

Carbon and water footprint of food choices by users of a hospital canteen

Diana Menis¹, Daniela Zago¹, Peter Cautero¹, Federica Fiori¹, Lucia Lesa², Alessandro Conte³, Maria Parpinel¹, Laura Brunelli⁴

¹University of Udine, Department of Medicine, University of Udine, Udine, Italy, ²Azienda Sanitaria Universitaria Friuli Centrale, ³Azienda Sanitaria Universitaria Friuli Centrale, Medical Directorate, Hospital of San Daniele-Tolmezzo, "Azienda Sanitaria Universitaria Friuli Centrale", San Daniele del Friuli, Udine, Italy, ⁴University of Udine; Azienda Sanitaria Universitaria Friuli Centrale, Department of Medicine, University of Udine, Udine, Italy; Accreditation, Quality and Clinical Risk Unit, "Azienda Sanitaria Universitaria Friuli Centrale", Udine, Italy

Background and Objective: Food production is responsible for 30% of global CO2 emission, with beef having the largest impact. In Italy the mean value of CF and WF for meal is 1112±867 gCO2eq. and 1083±858 L. Many articles have highlighted the contribution to a sustainable development through the selection of food. The aim of this study was to evaluate the sustainability of food choices in a hospital canteen.

Methods: The study was conducted in San Daniele del Friuli hospital for 5 consecutive days in September 2022 taking photo of the lunch trays of workers who have access to the hospital canteen and agree to participate. The participants were also asked to fill in a questionnaire. The photos were taken before the meal was consumed. The carbon footprint (CF) and water footprint (WF) of the recipes were estimated using the SU-EATABLE LIFE database.

Results: We analyzed 240 meals, 201 of which were paired with a completed questionnaire. Participants (N=201) were 61 men and 140 women with a mean age of 49±10 years (median=51). The median CF estimated was 778 (604–1085) gCO2eq./tray and the median WF was 892 (668–1170) LH2O/tray for the lunch meal. A higher median CF (1076 vs. 797 LH2O/tray; p<0.001) and WF (981 vs. 693 gCO2eq./tray; p<0.001) were observed in men compared to women. The 16% of the participants (4 men and 29 women on 201) chose vegetarian and vegan courses.

Conclusion: Carbon and water footprint values were lower than those reported in the literature, with women performing better and showing lower propensity to choose meat than men. Our low values could be related to the canteen menu not containing beef and to the high proportion of women in the sample. Targeted interventions for men may be needed to raise awareness on sustainable diet

through food choices.

Quantification Of waste in schools: a case study in danang city, Vietnam

Nguyen Huong¹, Hoang Linh², Nguyen Nga³, Tran Trung⁴, Ngo Ngoc³, Tran Huan⁵

¹Phan Chau Trinh University Phan Chau Trinh University 9 Nguyen Gia Thieu, Dien Ban district, Quang Nam province Viet Nam, ²Da Nang University of Medical Technology and Pharmacy 99 Hung Vuong street, Hai Chau district, Da Nang city Viet Nam, ³Center for adaptive capacity building research Center for adaptive capacity building research Viet Nam, ⁴Center for adaptive capacity building research Nguyen Tran Anh Vu Center for adaptive capacity building research Center for adaptive capacity building research Viet Nam, ⁵Da Nang University of Medical Technology and Pharmacy

Background: Waste is a major problem that can affect the environment and health; especially in developing countries where there is often a lack of an appropriate system for waste treatment. Understanding the current situation of waste, its common type, and its amount are important to develop appropriate strategies for waste control, especially in a school-based setting. This study has been conducted to identify common types of waste that are disposed of in schools and quantify such waste.

Methods: This study used an audit method to identify the common types of waste and quantify such waste in Da Nang in 2021.

Results: There were four schools with a total number of 3064 students who participated in this study. The average total volume of waste that schools discharge in a day is 460kg (accounting for 7542 liters of storage volume); in which, organic waste has the most enormous volume of 261kg (57% of total volume) accounting for 2262 liters (30% of total volume); non-recyclable waste weights 175kg (38% of the total volume) and a maximum volume of 4524 liters (60% of the total volume); recyclable waste has a weight of only 22kg (5% of total volume) and accounts for 719 liters (10% of total volume); The remaining types of waste are insignificant. This study also showed the presence of a large number of plastic bags (2128 pieces), multi-layer packaging (2036 pieces), milk cartons (1047 boxes), straws (772 pieces), plastic bottles (670 bottles), foam boxes (531 pieces), plastic spoon (400 pieces), polypropylene plastic cup (327 pieces) in the total waste produced in 01 days of these schools.

Conclusions: Schools are emitting a large amount of waste, significantly plastic waste. Intervention programs in school-based settings are needed to reduce waste to ensure childrens health and protect the environment.

Canidelo, 4400-712 Vila Nova de Gaia, ⁵Departamento de Medicina Preventiva, Faculdade de Medicina FMUSP, Universidade de São Paulo, SP, Brazil, ⁶Department of Public Health, History of Science and Gynaecology, Faculty of Medicine, Miguel Hernández University, Sant Joan d'Alacant, Alicante, Spain, ⁷CIBER in Epidemiology and Public Health (CIBERESP), Madrid, Spain

Background and Objective: Eco-anxiety describes the mental distress resulting from extreme concern about environmental circumstances as well as the effects of climate change. The study aims to measure eco-anxiety, identify its determinants, and assess the associations between eco-anxiety and health, as well as pro-environmental behaviors in participants of Generation XXI birth cohort at the ages of 16/17 years.

Methods: A cross-sectional evaluation based on a web-based questionnaire is currently on-going in the entire cohort (N= 8647). Eco-anxiety was assessed using Hogg et al. scale (2021), which was translated and culturally adapted to Portugal.

The Beck Anxiety Inventory was used to assess generalized anxiety. The adoption of pro-environmental behaviors was evaluated using an adapted version of the Kaiser et al. (2007) instrument. Eco-anxiety scale was categorized in quintiles. Linear and logistic regression were used to estimate associations.

Results: We found that 18.5% of the participants have some degree of eco-anxiety, scoring higher than 9 (scale from 39). Individuals in the top quintile (quintile 5) of eco-anxiety were more likely to be females [OR=3.9, 95%CI 1.9-8.1] and have poor self-rated health [OR=2.4 1.0-5.6] when compared to those with lower scores (quintiles 2-4). Higher levels of generalized anxiety were associated with higher eco-anxiety scores [β =0.16, 0.12-0.21]. Participants scoring higher in the eco-anxiety scale engaged more often in collective (e.g., activism [β =0.03, 0.01-0.04], nature conservation initiatives [β =0.06, 0.04-0.08]) and some individual pro-environmental behaviors (e.g., reduced meat consumption [β =0.06, 0.04-0.09], recycling [β =0.04, 0.01-0.07]). They also more frequently read/look for information about environmental problems [β =0.08, 0.05-0.10].

Conclusions: These preliminary results showed that eco-anxiety is more common in females and seems to be associated with generalized anxiety and poorer self-rated health. Eco-anxiety appears to prompt adolescents to adopt some proactive behaviors. Because the data collection is still ongoing these results should be interpreted with caution.

Per- and polyfluoroalkyl substances (pfas) and depression: Associations stratified by body fat level

Geraldo Neto¹, Gorazd Stokin², Anna Bartoskova Polcova³, Martin Bobak³, Ludek Blaha⁴, Juan Rivas⁵, Jana Klanova³

¹International Clinical Research Center Of St. Anne's University Hospital Brno (FNUSA-ICRC) Pekařská 53, 602 00 Brno Czech Republic, ²International Clinical Research Center Of St. Anne's University Hospital Brno (FNUSA-ICRC), ³Research Centre for Toxic Compounds in the Environment (RECETOX), Faculty of Science, Masaryk University, Brno, Czech Republic. Kamenice 753, 625 00 Bohunice Czech Republic, ⁴Research Centre for Toxic Compounds in the Environment (RECETOX), Faculty of Science, Masaryk University, Brno, Czech Republic, ⁵The International Clinical Research Center of St. Anne's University Hospital in Brno (FNUSA-ICRC) Pekařská 53, 656 91 Brno Czech Republic

Background and Objective: The extensive use and bioaccumulation of per- and polyfluoroalkyl (PFAS)-containing substances over time raise concerns about their health impacts, which include mental issues such as depression. However, there is a lack of studies about this relationship, especially in middle-aged and older adults. Thus, the present study aims to evaluate the association between PFAS and depression. In addition, considering the importance of PFAS in the promotion of adipogenesis, and the fact of obesity and depression share about 12% to 20% of pleiotropic genes, the analyses will also be stratified by the body fat status.

Methods: A cross-sectional study with 479 subjects (56.4% women, 25-89 years) was conducted. Four PFAS were measured in serum: perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), perfluorodecanoic acid (PFDA), and perfluorooctane sulfonate (PFOS). The depression was assessed by the Patient Health Questionnaire (PHQ-9) or the Center for Epidemiologic Studies Depression scale (CES-D). The body fat percentage was predicted on a scale with multi-frequency bioelectrical impedance analysis.

Results: The prevalence of high body fat and depression were respectively, 41.1% and 7.9%. The fully adjusted model included the co-variables: age, sex, educational level, income, smoking, physical activity, and the questionnaire to assess depression. Only PFOA was significantly associated in the whole sample (Prevalence Rate - PR:1.95 Confidence Interval-CI 95%:1.04-3.65). However, in the group with normal adiposity, PFOA (3.11, CI95%:1.53-6.34), PFNA (2.54, CI 95%:1.32-4.90), and PFDA (2.10, CI95%:1.09-4.01) were also significant.

Conclusion: After stratifying the sample, associations with depression became more apparent in three of the four PFAS in the group with normal adiposity. Future research should investigate the role of obesity, as well as the biological plausibility and possible mechanisms increasing the limited number of evidence on the effect of PFAS on public mental health.

Evidence and practical insights on participation of vulnerable population groups and transdisciplinarity in the context of urban health

Janna Leimann¹, Patricia Tollmann¹, Heike Köckler¹, Eike Quilling¹

¹University of Applied Sciences Germany

Background and Objective: Social inequities in health are increasing in cities, particularly affecting certain sociodemographically defined communities, which are therefore more vulnerable than others. The urban health approach offers opportunities to promote health equity. Therefore, the participation of vulnerable groups is a promising strategy.

A transdisciplinary project on urban health in the Ruhr area (MUHR) investigates the international state of research on participation of vulnerable groups in the context of urban health. The objective is to present results on participation methods used, stakeholders involved, and the role of transdisciplinary collaboration.

Methods: To meet this objective, a systematic review was conducted and complemented by focus groups with experts from different disciplines related to urban health and participation. To adequately represent multisectoral aspects, social, medical and health science databases were systematically searched (PubMed, AgeLine, CINAHL Complete, APA PsychArticles and PsychInfo, SocINDEX, LIVIVO). International publications of the last ten years in English and German were considered. Two researchers screened independently considering defined exclusion criteria. The focus groups will address the identified research gaps and take place within a transdisciplinary forum.

Results: Of initially 841 manuscripts found, eight met the inclusion criteria and were included in the qualitative analysis. It can be increasingly seen that different disciplines are involved in the creation of healthy cities in the sense of transdisciplinarity and that the commitment to work together can represent an opportunity to support citizen empowerment. Commonly used methods for participation include Photo Voice, workshops, co-creation or community forums. The results of the focus groups will be available in February 2023 and will enrich the results with practical content.

Conclusion: The findings provide insights into the opportunities of urban health to promote health equity and public health in general. They represent direct impetus for structural change i.e. towards more community engagement in cities.

The case for indoor temperature in heat health warning systems: deployment of a real-time indoor temperature data ecosystem in community housing

Arlene Oetomo¹, Jasleen Kaur¹, Kang Wang¹, Zahid Butt¹, Peter Berry², Plinio Morita¹

¹University of Waterloo Canada, ²Health Canada

Heat waves are a major global public health concern and present a significant challenge to society, especially to underserved populations and those aged 50+, due to their increasing frequency and intensity. They also add significant burdens to the healthcare systems resources, and it has been shown that most deaths occur indoors. Still, our warning systems are based on outdoor temperature measurements. We have developed a real-time indoor temperature alert ecosystem that can capture indoor temperatures that may aid in assessing and responding during a heat wave. We placed ecobee smart thermostats into community housing homes with community housing partners and local health authorities (N = 70), recorded indoor temperature data in near real-time, and administered three surveys during the study period. We investigated: (i) indoor temperatures trends during the heatwave season of 2022 in Vancouver and Ottawa, Canada; (ii) behaviours of participants during this period; (iii) housing characteristics; (iv) delivery of time-sensitive temperature alerts to enable check-ins on participants, and (v) perceptions to heat risk and methods of communication. Initial results shows different observations that includes: a) unsafe indoor temperatures were reached and persisted (above 26°C and 31°C) despite a milder heat wave season than the previous year (in BC); b) gaps in understanding of best practices to stay safe exist; c) home characteristics increase risk of overheating; d) coordinating with community housing to check-in can protect individual health; and e) ensure individuals are protected during extreme heat events. Results suggest that implementing indoor temperature provides vital information to inform heat health response plans. The smart thermostat technology can be retrofitted into homes in Canada as it is commercially available. This study presents a scalable solution for monitoring indoor temperatures. It demonstrates how smart thermostats can monitor indoor temperature exposure conditions to prevent deaths during extreme heat events.

Modelling the Impact of Seasonal Climate Variability on Health Sector in Mozambique

Américo José¹, Tatiana Marrufo², Rachid Muleia³, Eduardo Gudo¹, Kathryn Colborn¹, Genito Maure⁴, James Colborn⁵

¹National Institute of Health of Mozambique Ministry of Health of Mozambique Estrada Nacional Nacional N°1, Bairro da Vila - Parcela n° 3943, Marracuene, Mozambique Micronesia, Fed States, ²National Institute of Health of Mozambique, ³Eduardo Mondlane University Ministry of Science and Technology 3453 Avenida Julius Nyerere, Maputo Mozambique, ⁴Eduardo Mondlane University Ministry of Science and Technology Estrada Nacional Nacional N°1, Bairro da Vila - Parcela n° 3943, Marracuene, Mozambique Mozambique, ⁵Clinton Health Access Initiative United States

Introduction: Seasonal climate variability impacts the health of millions of population around the world. The incidence of malaria increase in many regions of the world, mainly in Mozambique, as a result of variability in rainfall, minimum and maximum temperatures. Malaria is a Public Health problem in Mozambique. **Methodology:** Weekly Malaria data were extracted (2008 – 2022) from the Weekly Epidemiological Bulletin provided by Ministry of Health of Mozambique and climate data were derived from the European Center for Medium-Range Weather Forecasts. Pearson Correlation Coefficient (r) was used to determine the correlation between rainfall, minimum and maximum air temperature and weekly malaria incidence. We used the Distributed Lag Non-Linear Models (DLNMs) to estimate the favorable thresholds of climatic variables to increase the relative risk (RR) of weekly malaria incidence. The “Generalized Additive Model (GAM)” was applied to estimate positive cases of malaria in the rainy season (October – March) in Mozambique.

Results: In the northern region of the country, the province of Nampula had the highest positive correlation for the increase of malaria with the rainfall at lags around 4 and 5 (r=0.47), mainly when the rainfall reaches 250 mm (RR=85%) and 15 °C (RR=75%) of minimum in a given epidemiological week. In the central region, positive cases of malaria are severely impacted by rainfall in Zambézia province, at lags 3 or 5 (r=0.20&r=0.18) and reach their peak prevalence of the disease when 400 mm of rainfall (RR=88%) is recorded. In the southern region, the province of Inhambane increased the malaria incidence when the rainfall was at lags 1 and 11 (r=0.80 Climate; Malaria).

Cardiovascular health effects of outdoor air pollution in the most polluted city, Mongolia

Nandin-Erdene Bayart¹, Gavin Pereira², Christopher Reid¹, Krassi Rumchev¹

¹Curtin University Institute of Medical Sciences, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia Kent St, Bentley, WA 6102, Australia Australia, ²Curtin University

Background: Cardiovascular disease (CVD) are the leading cause of death globally. A major contributor to CVD mortality and morbidity is ambient air pollution (AAP) exposure. The AAP level in the capital city of Mongolia is considerably higher than the World Health Organisations air quality guideline. The main source of AAP is related to the traditional houses where people burn raw and processed coal for heating and cooking purposes. Although several studies have reported the association between AAP and CVD outcomes worldwide, scientific evidence in Mongolia is lacking. The purpose of this study is to evaluate associations between air pollution and CVD mortality in Ulaanbaatar.

Methods: We collected air pollution and meteorological data from the Centre for Environmental Monitoring and mortality data from the Health Development Centre between January 2014 and December 2021. Six criteria air pollutants were measured at 15 monitoring stations, including particulate matter with an aerodynamic diameter $\leq 2.5 \mu\text{m}$ and $\leq 10 \mu\text{m}$ (PM_{2.5} and PM₁₀), nitrogen dioxide (NO₂), sulphur dioxide (SO₂), ozone (O₃) and carbon monoxide (CO). An ecological time-series analysis was applied to examine the relationship between exposure and outcome variables.

Results: The highest concentrations of AAP, except ozone, were reported in winter. The average concentration of PM_{2.5}, PM₁₀, NO₂, SO₂, O₃ and CO were 118.2±73.8 $\mu\text{g}/\text{m}^3$, 219.8±119.6 $\mu\text{g}/\text{m}^3$, 76.1±20.3 $\mu\text{g}/\text{m}^3$, 71.9±52 $\mu\text{g}/\text{m}^3$, 21.9±19.8 $\mu\text{g}/\text{m}^3$, 1.8±1.07 mg/m³ respectively. A total of 33,931 deaths were identified, most of which occurred during cold seasons. In a multiple pollutant model, PM_{2.5}, PM₁₀ and SO₂ were significantly correlated (P-value<0.05) with CVD death, accounting for seasonal variations after adjusting other pollutants.

Conclusion: This research found evidence of a positive association between short-term exposure to PM_{2.5}, PM₁₀ and SO₂ and CVD mortality. These study findings provide evidence-based information for further research and policymakers to reduce current air pollution level in Mongolia.

Gender-specific variables of climate-change related health

Impacts: a global south perspective

Nilanjana Ganguli¹, Nilanjana Ganguli², Ann LeHolland³

¹Dahdaleh Institute for Global Health Research Canada, ²Dahdaleh Institute for Global Health Research, York University Canada, ³University of California, Irvine

Background and objective: Gender is critical for assessing the economic and social costs associated with climate change. Health impacts of climate change on women differ from impacts on men owing to complex social contexts and adaptive capacities. The objective of this study is to identify interactions within and across four subsystems—food security, communicable and non-communicable diseases, ecological services, and extreme weather—and their influence on gender-specific health impacts.

Methods: A systematic literature review guided by the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) framework was conducted to generate the database. From 62 included articles, information was extracted on health-related variables, climate induced change in the variable (positive or negative), exposure pathways and their resulting health impacts. An Influence Diagram was then developed to visualize the cause-and-effect relationships within variables and help explain the change in variables over time. A bibliometric analysis was conducted to understand the status of gender-focussed research in climate-change and health.

Results: 53 gender-specific variables were identified, with socio-economic variables playing a more dominant role than environmental. Gender was discussed most in relation to food security and least in relation to communicable and non-communicable diseases. The bibliometric analysis showed an upward trend in studies focussed on gender and climate change since 2015, and 53% of the articles were a collaboration between male and female authors.

Conclusion: Overall, women and girls are more susceptible to climate change. In certain situations, men have shown higher vulnerability to climate change than women. Hence, generalization of women to be the highest at-risk category in all climate change related situations should be consciously avoided. Understanding the complexity arising from multiple interacting variables requires holistic and context-specific research approaches.

Legionella contamination and human health: the risk of wastewater reuse in agriculture

Sara Bonetta¹, Cristina Pignata², Lisa Richiardi¹, Silvia Bonetta³, Elisabetta Carraro²

¹University of Torino Department of Public Health and Pediatrics, University of Torino, Torino Italy, ²University of Torino, ³University of Torino Department of Life Sciences and Systems Biology, University of Torino, Torino Italy

Background and objective: Wastewater reuse is a promising alternative source of water supply considering the water scarcity related to climate change. However, if not adequately treated, wastewater represents a source of microbiological health risk. The wastewater reuse in agriculture can promote the production and dispersion of aerosol containing pathogens such as Legionella opening new risk profiles for human health. The purpose of the study was to investigate risks related to Legionella occurrence in wastewater samples reused in agriculture.

Methods: Legionella (spp. e pneumophila) were monitored using both culture and molecular (qPCR) methods in influents (n=21) and effluents (n=21) of 3 wastewater treatment plants (WWTPs) equipped with treatments suitable for wastewater reuse (WWTP1 and WWTP2 with membrane bioreactor-MBR system and WWTP3 with ClO₂ disinfection)

Results: The qPCR revealed Legionella spp. presence in all samples. L. pneumophila was detected in 86% and 57% of the WWTP1 and WWTP2 influents and in all pre-disinfected samples of WWTP3, while only some WWTP3 effluents were contaminated. A significant reduction in Legionella contamination was obtained only with MBR highlighting that this treatment allows to control Legionella contamination. A lower Legionella contamination was observed with culture method respect to molecular one. The significant correlation between Legionella presence and physicochemical characteristics of wastewater (BOD-biochemical oxygen demand, COD-chemical oxygen demand, TSS-total suspended solids) highlights the possibility that these parameters support the risk evaluation of Legionella occurrence in wastewater.

Conclusion: Results obtained highlight the need to carry out further investigation on Legionella contamination in wastewater samples when the reuse of the effluents in agriculture is purposed. The use of molecular method could allow more precautionary risks estimation. This is particularly important considering that aerosol formation from wastewater contaminated by Legionella could represent an occupational health risk associated with reuse.

Arboviral transmission risk as driven by aedes aegypti resistance to insecticides and eco-bio-social factors in disease foci, côte d'ivoire

Julien Zahouli¹, Claver Adjobi², Pie Müller³

¹Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte d'Ivoire. Vector Control Unit "Adiopodoumé, KM 17, Route de Dabou 01 BP 1303 Abidjan 01 Côte d'Ivoire" Ivory Coast (Cote D'Ivoire), ²Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte d'Ivoire., ³Swiss Tropical and Public Health Institute Vector Biology Unit Switzerland

Background: Our ability to deal with Aedes mosquito-borne arboviral outbreaks in Africa is still limited. Thus, we assessed the risk of transmission arboviruses (e.g., dengue and yellow fever) and Aedes aegypti susceptibility to insecticides and breeding eco-bio-social determinants in disease foci in Côte d'Ivoire.

Methods: We sampled Ae. aegypti larvae and breeding sites, and household socio-ecological data in arboviral foci in Côte d'Ivoire from June to December 2020. We collected Aedes mosquito samples in two rubber tree areas (Koffikro and Samo), two oil palm areas (Ehania, and Agbaou), and two urban neighbourhoods (Bingerville and Cocody). Aedes larval indices (container index: CI, household index: HI and Breteau index: BI) were determined. Moreover, we tested Ae. aegypti larvae and adults against insecticides (DDT and deltamethrin), and recorded the mortality.

Results: The most productive Ae. aegypti breeding sites were tyres, discarded cans, water storage containers and rubber latex collection cups. Stegomyia indices were highest in urban areas, followed by rubber areas and oil palm areas, with HI of 98.3, 81.2 and 67.82 CI of 69.7, 57.3 and 29.5, and BI of 99.7, 65.9 and 13.8, respectively. Ae. aegypti showed possible resistance to deltamethrin (mortality: 87.3-90.8%) rubber and oil palm areas, and resistance to DDT (mortality: 57.3-60.1%) in urban neighbourhoods and permethrin (mortality: 79.5-85.4%) in rubber and oil palm areas. Ae. aegypti larval infestation was correlated with complex community behaviours, including water storage practices and solid waste management. Ae. aegypti breeding sites' positivity was associated with unmanaged solid waste, water supply interruptions, water storage duration and insecticide-susceptibility status.

Conclusions: In Côte d'Ivoire, Ae. aegypti larval indices and arbovirus transmission risk were correlated with socio-ecological factors and insecticide-resistance level. Integrated community-based vector control is recommended.

Prevalence of environmental certificates in unhealthy foods commercialized in Brazilian retail

Carolina Kikuta¹, Camila Borges², Ana Duran³

¹State University of Campinas Brazil, ²Center for Epidemiological Research in Nutrition and Health, ³Center for Food Studies and Research Brazil

Background and Objectives: Environmental certification used by food industries has been increasing aiming to show concern with environmental impact. Consumers' interest in green products is also increasing. This study aims to analyze the most prevalent environmental certification types on food and beverages packaging marketed on Brazilian retail and analyze their nutritional profile.

Methods: The analysis was conducted with 7,726 products founded in Brazilian retail between 2018 and 2021. Data were collected by trained researchers using images from all sides of the package. The products were classified by the NOVA classification in unprocessed and minimally processed foods, culinary ingredients, processed foods and ultra-processed foods. Nutritional profile was analyzed according to Pan-American Health Organization (OPAS). Were calculated the prevalence of types of environmental certificates according to NOVA and the proportion of products with certifications and high in critical nutrients.

Results: A total of 1,753 products had environmental certification on food packaging (22.7%). The most prevalent type was related to conservation of fauna and flora as the following certifies: FSC Mix, Projeto Tamar, SOS Mata Atlântica, Certified Humane Brasil, Dolphin Safe and Best Aquaculture Practice (45.9%), followed by transgenic certified (33.4%) and organic certified (10.5%). Environmental certifications were more prevalent on ultra-processed foods (81.9%) than processed foods (7.5%), culinary ingredients (2.6%) and unprocessed and minimally processed foods (19.7%). The most frequent certification on ultra-processed foods were related to conservation of fauna and flora (36.7%), and transgenic (30.9%). Between the products with environmental certifications, 22.8% of the ultra-processed and 19.0% of the processed were high in at least one critical nutrient.

Conclusion: Ultra-processed foods high in at least one critical nutrient showed more environmental certification on their packaging. This fact can cause misunderstanding among consumers who are concerned about environmental issues since ultra-processed foods are unhealthy.

Incidence tendencies and projection of climate sensitive diseases in mozambique

Oswaldo Inlamea¹, Érico Langa¹, Tatiana Marrufo¹, Américo José²

¹Instituto Nacional de Saúde Mozambique, ²Instituto Nacional de Saúde Oswaldo Inlamea Mozambique

Background and objective: Changes in climate patterns have been reported around the world. There is evidence that such changes can affect human health, particularly with climate sensitive diseases like Malaria and diarrhea. This effects are exacerbated in low and middle-income countries such as Mozambique. Thus, this study aimed to determine climate sensibility of Malaria and Diarrhea as well as the behavior they can take in the face of climate change.

Methods: Eight districts of Mozambique were selected. Malaria and diarrhea incidence data was obtained at Weekly Epidemiological Bulletins. Pearssons Correlation Coefficient was determined and Poisson's regression with distributed lags was used to determine relationship between the incidences, temperature and precipitation. Projections of climate change impact were determined based on IPCC emission scenarios. All analyzes performed using the R statistical software. Results: Positive correlation between diarrhea cases and precipitation and negative correlation between Malaria and maximum temperatures were observed. There is a high probability of an increase in the incidence of diarrhea if precipitation above 50 mm occurs. Thresholds of minimum temperate that favor an increase in Malaria vary from 17oC in Lichinga to 24 oC in Angoche, Beira and Tete. The models indicated to a possible increase in the incidence of Malaria in the low emissions scenario in all districts, except in Angoche and Moamba, where the low emissions scenario show a probable decrease in the incidences. The models also showed to a possible increase of diarrhea in the long term, with up to 35% increase in Mabalane district.

Conclusions: The analyses showed weak to moderate correlation between climatic variables and studied diseases. Precipitation most influences diarrhea cases, while Malaria is most influenced by minimum temperatures. According to the models, the incidence of both diseases will probably increase in most studied districts.

Does the proportion of children with limited day-to-day activities affect the provision of accessible and inclusive public playground in London?

Hynek Pikhart¹, Katerina Pikhartova², Aissa Gomez², Jitka Pikhartova³

¹UCL London United Kingdom, ²The Manchester School of Architecture United Kingdom, ³UCL IEHC London United Kingdom

Whilst play is a fundamental right of every child, and has been continually shown to provide opportunities for social, physical, cognitive and emotional development, a general lack in play provisions for children with disabilities has been reported in the past. Additionally, it has been suggested that the word 'inclusive' is regularly misused in playground guidance and play equipment providers. The study aim was to investigate the playground provision in London, and to assess whether boroughs, with the highest, mid- and lowest proportion of children with limited day-to-day (LDTD) activities (as classified by ONS), offer residents accessible and inclusive public play areas, and whether there are any differences between these boroughs. Four boroughs were selected to represent each of the three categories, and 20% of randomly selected playgrounds were then thoroughly investigated in each borough for accessibility and inclusivity. Borough-level analysis was conducted to assess the association between proportion of children with LDTD activities and average playground inclusivity scores. This analysis was then adjusted for different social and economic indicators including Index of Multiple Deprivation (IMD). Results showed that 1% increase in the proportion of children with LDTD activities was associated with a 0.82point decrease in the borough's average playground score. Further analysis suggested that this association may be, at least partly, due to the socioeconomic characteristics of the different boroughs. When the analysis was adjusted for the 2019 IMD the effect was reduced to 0.19points, (77% reduction of original association). Accounting for IMD data, a clear trend emerged showing that boroughs with lower financial deprivation commit more resources to providing accessible playgrounds for their residents. The study further highlights that designing for 'inclusive' spaces is generally poor

in London, even poorer in more deprived areas, suggesting designers should be more proactive in engaging with existing resources related to children's play.

A novelty strategy on adaptation for climate change in defense of climate justice was made in antioquia, colombia

Eliana Herrera¹, Camilo Molina-Betancur², Eliana Martínez-Herrera³, Camilo Molina-Betancur⁴

¹National School of Public Health Professor "62 St # 52 -59 33rd Building Medellin, Colombia, ²National School of Public Health UA, Colombia,

³National School of Public Health UA Professor Colombia, ⁴National School of Public Health Researcher Colombia

The implementation of strategies and actions to reduce social, economic and environmental health risks and vulnerabilities due to the climate crisis was possible in Antioquia because of the declaration of the emergency in the territory. In the formulation process, 4 major components were identified, a baseline or diagnosis, a vulnerability analysis, a strategic component to act against these problems and the transversally to the previous components through a participation, dissemination and public communication mechanism. Some important findings at the departmental level have to do with low institutional capacities in environmental health at the municipal level. It was identified how certain productive sectors (mining, agriculture and construction) increase the impacts on water, air and soil, increasing the probability of further damage in the face of the growing increase in extreme weather events such as fires, windstorms and floods, and increasing in turn the rates of morbidity and mortality from related diseases. Thus, the need for promotion and prevention programs in environmental health is evident to reduce the effects on health due to the effects of climate change. 45 adaptation strategies were formulated with short, medium and long-term actions, where strategies that provide mitigation co-benefits stand out, others are those based on socio-ecosystems and communities, or on the improvement of basic infrastructure and development sectors, coordination with risk management and those that promote the strengthening of institutional and community capacities. They were held many roundtables with the participation of more than 1,200 people, where the participating actors recognized the effects of climate change related them to health. This has been an opportunity to recognize that health must be transversal in all policies, which strengthens intersectoral and transectoral dialogue and synergies can be generated in resources, not only financial, but also human and technical knowledge.

Assessing the impact of air pollution on health outcomes using IoT sensors

Shahan Salim¹, Plinio Morita²

¹University of Waterloo Canada, ²University of Waterloo

Background and Objectives: Air pollution is a global public health concern. It is responsible for a cascade of adverse health outcomes ranging from minor physiological impacts to deaths from respiratory and cardiovascular diseases. Despite these increasing threats, current surveillance ecosystems cannot monitor indoor and outdoor air pollution levels to provide early warnings for high-risk individuals. Air pollution alerts are based on ecological data collected from outdoor air quality monitoring stations, limiting the ability to monitor individual-level exposure and provide recommendations on managing the impacts of air pollution.

The advancement of IoT and big data technologies can now allow public health officials and researchers to monitor air pollution levels and take appropriate and rapid actions to mitigate the harm.

Methods: We have partnered with UNICEF Mongolia to assess the impact of air pollution on health. Air pollution data were collected from 12 air quality monitoring stations placed across Ulaanbaatar, Mongolia. The National Center for Public Health (NCPH) provided public health data in form of ICD-10 codes for 2019 and 2020.

Results: We tested for exposure-outcome relationship using logistic regression models. Preliminary results indicate a mean PM10 is 139.7; and PM2.5 is 71.7. Results indicate hypertension (ICD I10) to be the most prevalent disease in the population. Acute tonsillitis (J03), acute bronchitis (J20), acute nasopharyngitis (J00) round out the top 4 diseases. We did not observe any relationship (OR 1.01; 95% CI 0.9-1.04) between high exposure to air pollution with rates of hypertension. Other outcomes are still being explored.

Conclusion: This study is a stepping-stone for using IoT based air pollution data to assess its impact on human health at a population level.

Estimating the environmental impact of antibiotics through drug utilisation and eco-toxicological data: The Italian context

Carlotta Lunghi¹, Valentina Giunchi¹, Michele Fusaroli¹, Emanuel Raschi¹, Elisabetta Poluzzi¹

¹University of Bologna Italy

Introduction: Antibiotics use in Italy is among the highest in Europe. This overuse can lead to anti-microbial resistance and harm humans, animals, and plants. Their accumulation in surface waters, and its consequent toxicity for animals and plants, is an emerging problem. This study aimed to estimate antibiotics environmental impact on the Italian surface waters.

Method: We integrated drug utilisation and eco-toxicological data to assess antibiotics burden on the Italian surface waters. We extracted the predicted no-effect concentrations (PNEC) from the European Medicines Agency (EMA) and the Swedish Medicines Agency (FASS) environmental risk assessment reports. We then estimated the Italian predicted environmental concentrations (PEC). We used Italian drug utilisation data for 2020, the total number of inhabitants on January 1st, 2020, and the default values proposed by the European Chemical Agency for wastewater production and disposal. We calculated the environmental risk as PEC/PNEC ratio and classified it as high (>10), moderate (>1), low (>0.1), and insignificant (≤0.1).

Results: We obtained the environmental risk for 56 antibiotics for which Italian consumption data were available. We found a high environmental risk for one glycopeptide (vancomycin: PEC/PNEC=71.002), two penicillins (ampicillin: 43.376; amoxicillin: 41.346), one cephalosporin (cefazolin: 26.201), and one macrolide (azithromycin, 10.263). The risk was moderate for two fluoroquinolones (levofloxacin: 8.333; ciprofloxacin: 3.371), three cephalosporins (ceftriaxone: 5.823; cefepime: 2.147; cefixime: 1.867), two penicillins (piperacillin: 3.194; flucloxacillin: 1.377), and one macrolide (clarithromycin: 2.917). Vancomycin, azithromycin, ciprofloxacin, levofloxacin, ceftriaxone, cefixime, piperacillin, and clarithromycin are also on the Watch group of the AWaRe classification.

Conclusions: Multiple antibiotics have a high/moderate environmental impact on Italian surface waters, most of which have a relatively high risk of selecting bacterial resistance (those in the Watch group). Appropriate prescription and adherence practices of these antibiotics may reduce the negative impact on the environment and improve purification procedures and green drug development.

Lead exposure is associated with reduced brain electrical activity in cognitively unimpaired older adults

Kyoung-Bok Min¹, Jin-Young Min²

¹Department of Preventive Medicine, College of Medicine, Seoul National University, Seoul, Republic of Korea, ²Veterans Medical Research Institute, Veterans Health Service Medical Center, Seoul, Republic of Korea

Background and Objective: Lead is a ubiquitous environmental pollutant affecting the central nervous system. Many studies have provided evidence that exposure to lead causes reduced cognitive performance or structural changes in the brain. Despite these neuroscientific studies, no study has yet investigated the association between body lead level and the brain electrical activity (which indicates cognitive dysfunction in the brain). This study examined the association between blood lead level and electroencephalography (EEG) in cognitively unimpaired older adults. **Methods:** A total of 93 cognitively unimpaired older adults (60 years or older) was included in this study. The level of cognitive function or impairment was evaluated by neurologists diagnose. EEG is a non-invasive method that records the brain electrical activity via electrodes placed on the scalp. A cap-type wireless EEG device was used for EEG recording, with linked-ear references based on a standard international 10/20 system. Blood lead levels were measured by inductively coupled plasma mass spectrometry. Multiple linear regression was employed to analyze relationships between lead and EEG features of the frontal, central, parietal, temporal, and occipital regions.

Results: The mean age of study population was 71.5 years, and 46.2% were female. The mean blood lead level was 1.60 µg/dL. We found a significant association between lead and EEG features. Specifically, elevated blood lead levels were significantly and negatively associated with EEG activity in the brains central, temporal, and occipital regions. The most robust finding was observed in occipital lobes, which are located at the very back of the brain and responsible for the visual processing area of the brain. The association was independent of covariates (i.e., age, gender, income, health behaviors, and chronic conditions). **Conclusions:** Environmental exposure to lead may be associated with cognitive performance

via reduced brain electrical activity in the central, temporal, and occipital lobes.

Dengue fever complex over climate change scenario in Rio de Janeiro state (Brazil)

Antonio Carlos Oscar-Júnior¹, Pedro Henrique de Castro¹

¹Rio de Janeiro State University, Rio de Janeiro, Brazil, ²Programa de Pós-Graduação em Geografia, Rio de Janeiro State University, Rio de Janeiro, Brazil

Dengue fever is currently considered the most important arbovirus in the world and since its reintroduction in Rio de Janeiro, in 1986, it has become endemic, with epidemic periods. In 2022, there are 1.3 million probable cases and 951 confirmed deaths across Brazil. It is a disease strongly associated with urban characteristics and climate due to the adaptation and development characteristics of the *Aedes aegypti* vector. Given this background, this study evaluated the relationship between global climate change and the risk of dengue fever diseases for the state of Rio de Janeiro. The projection of future climate susceptibility to vector proliferation in the scenarios RCP 4.5 (stabilization level) and 8.5 (high level) between 2011-2040 and 2041- 2070 were assessed using two models: Eta HadGEM2-ES and EtaMIROC5 considering relative humidity (RH), annual percentage of days with minimum temperature higher than the 90th percentile (TN90p), days in the year with precipitation higher than 10mm (R10), grouped by seasons. The results indicate that the tendency of thermal and hygrometric elevation may have repercussions on the intensification and spatial expansion of the risk of arboviral diseases in the state of Rio de Janeiro, since there is a spatial and temporal expansion of the optimal environmental conditions for the development of the vector. Such findings affect, above all, public health strategies, which are still based on the prevalence of the disease in summer and autumn. Both models used (Eta HadGEM2-ES and Eta MIROC5) point to an intensification of the dengue fever risk in all state of Rio de Janeiro, including Mountain Region, nowadays the lower in cases. This intensification results mainly from the gradual increase of the minimum temperature and warm nights over the future periods, important conditions for the spread of the disease, since they favor the development of the vector-mosquito.

Urban environment walkability and its relation with Noncommunicable Diseases: a scoping review

José García-Abajo¹, Marilina Santero², Ivan Solà³, Gerard Urrutia³, M. Puig¹

¹Hospital de la Santa Creu i Sant Pau, Spain, ²Iberoamerican Cochrane Centre, Biomedical Research Institute Sant Pau, Spain, ³Iberoamerican Cochrane Centre, Biomedical Research Institute Sant Pau (IIB Sant Pau), Spain

Background: The walkability of the urban environment is the facility of walking around the urban area. This includes the availability of safe and well-designed roads, air quality, green spaces, and cycling infrastructure among other features of the environment. Walking is proven to improve health, but not all urban spaces are equally walkable.

Aim: To explore the impact of the urban environment walkability on the prevalence and development of chronic non-communicable diseases (NCDs).

Methods: A scoping review will be conducted following the standards of the Joanna Briggs Institute and PCC framework. The results will be reported in accordance with the PRISMA-ScR statement. The review will contain articles published between 2001 and 2020 in the Medline and Embase databases. Systematic reviews, ecological studies, clinical trials, quasi-experimental and observational studies that meet the eligibility criteria will be included. The impact on outcomes such as physical activity, obesity, blood pressure, hypertension, diabetes, and others like mental health, quality of life, and healthy behaviors will be explored. **Expected results:** This study will help to identify how walkable environments are associated with NCDs. Furthermore, emphasize how the importance of considering indicators of the walkability of the urban environment when planning, designing and implementing public health interventions. This scoping review will identify the feasibility of urban environments to promote physical activity and better health outcomes.

The benefits of walkability: application and limits of the Walking Suitability Index of the Territory in L'Aquila

Melissa Corradi¹, Riccardo Mastroantonio¹, Stefano Greco^{2,3}, Leila Fabiani^{1,2}

¹Department of Life, Health and Environmental Sciences, University of L'Aquila, Italy, ²Italian Society of Hygiene, Preventive Medicine and Public Health, Italy, ³ASL Teramo, Italy

Background: There is an interdependence between the favorable environment and the state of individual and collective well-being, also determined by physical activity, for this reason the new concept of city should provide places that encourage active mobility: "point models" can be used to assess whether a city facilitates it and compare zones or cities. The University of L'Aquila wants to evaluate and compare the walkability of areas in the city of L'Aquila.

Methods: Applying the model on three areas of the city of L'Aquila, Pettino, Coppito, hospital area, and analyzing practicability, safety, urbanity and pleasantness, each category was divided into three indicators, which were assigned a numerical rating from very bad to very good: through the model formula, the Walking Suitability Index of the Territory (T-WSI) for each category and the Street Index-SI1 for each zone have been calculated.

Results: The application of the algorithm allowed to obtain the following average values on base 100.

Practicability Safety Urbanity Pleasantness SI1 34.2 43.9 5.1 81.7 41.2 COPPITO 46.3 15.5 15.5 83.5 40.3 PETTINO 56.68 64.46 15.5 83.7 55.4 HOSPITAL The data indicate in Coppito quantity and quality of pavements very bad in almost half of cases, the area of the hospital is on average safer than the other two but in a quarter of cases received a vote of 0. It is, however, the urbanity (breadth, furniture and activity in the streets) to be globally more lacking, while the pleasantness is the parameter where the three areas have higher scores, hosting green areas not approachable.

Conclusions: The strong limit in the model method is represented by not having discriminated green areas usable by areas that are not, describing the suburbs as livable. Future project is to critically analyze the T-WSI considering urban maps that discriminate the different types of green areas.

The future risk and prevention of climate-change induced arboviral diseases in the European Union through a planetary health perspective: a systematic literature review

Lena Mende¹, Pierre Thomas²

¹Maastricht University, The Netherlands, ²Maastricht University, Netherlands

Introduction: Climate Change redefines the spread of arboviral diseases. The European Union is becoming increasingly active in implementing adaptation and mitigation strategies, to limit greenhouse gas emissions and prevent adverse climate change effects.

Methods: A systematic literature review of 139 Reports using the PRISMA flowchart was performed to gather secondary data.

Results: The arboviral species Ixodes ricinus ticks, Aedes aegypti- and Aedes albopictus mosquitos, their spread, and the associated infectious diseases of dengue, zika, and chikungunya, tick-borne encephalitis, and Lyme borreliosis, are identified as the most important vectors in Europe. The European Union is increasingly reliant on One Health approaches to enact environmental policy, and aims at improving surveillance and data sharing, as a spread of arboviral diseases resulting from Climate Change is expected.

Discussion: The spread of the assessed arboviral diseases is predicted, current models however fail to predict the spread at the regional level. European Policy is present, but a more coherent shared vision is needed to enable better local, national and supranational decision-making. Inclusion of planetary health, one health and Nature-based Solutions offer increased biodiversity, human, environmental and animal health protection. The effectiveness of recent EU action remains to be established.

Conclusions: The European Union needs enhanced surveillance systems that can predict high-risk areas for the emergence and spread of diseases are necessary, to effectively protect the European region from the growing infectious disease risk. Nature-based Solutions hold the capacity to protect human and environmental health better, and, if efficiently researched and implemented, incorporate cross-sectoral decision-making and lower intervention costs.

Effect of climatic factors favoring dengue transmission in Islamabad Capital Territory, Pakistan, 2022

Nadia Noreen¹

¹Directorate of Central Health Establishments(DOCHE), Ministry of National Health Pakistan, Islamabad, Pakistan

Background: Dengue fever (DF) is a national public health problem in Pakistan.

Dengue is a crucial vector-borne viral human disease widespread throughout the tropical region, with local risk variations affected by rainfall, temperature, humidity, and unplanned rapid urbanization. The dengue epidemic is a major public threat in Pakistan since 2005. Dengue fever is now endemic in Pakistan throughout the year circulation of four dengue serotypes with a peak incidence in the post-monsoon period (September-November). This study investigates the impacts of climatic factors (temperature and rainfall) on DF transmission in the Islamabad Capital Territory, through statistical approaches.

Methods: A time series analysis of the climatic factors was used to explore the climatic variability from 2015 to 2022. Furthermore, multiple linear regression analysis was used to measure the simulating effect of climatic factors on dengue outbreaks in ICT from 2015 to 2022.

Results: The time series analysis revealed significant annual and monthly variability in climatic factors, favoring a dengue-supporting environment. A positive temporal relationship between climatic factors (rainfall and increased temperature) and DF was observed. Moreover, a substantial monthly relationship between climatic factors and dengue incidence was revealed by the regression analyses. The linear regression of rainfall versus dengue showed monthly R² = 21.3%, whereas temperature versus dengue presented R² = 42.1%. A monthly significance R² = 54.6% was observed by the multiple regression analysis.

Conclusions: This study provided a substantial consensus on climatic factors influences on dengue transmission in the Islamabad Capital Territory, Pakistan. An increasing dengue transmission risk is associated with frequent climate changes. The disease prevention strategies by public health authorities should emphasize the integration of the health prediction modeling of dengue regarding influences of climate variability which can be replicated and applied in other subtropical and temperate climates zones of Pakistan.

Epidemiological profile of dengue in State of São Paulo/Brazil from 2010 to 2021

Lisie Justo¹, Amarylis Gardin¹, Heber Babosa¹, Luiza Carminatti¹, Otavio Ravazzi¹

¹Faculdade São Leopoldo Mandic de Araras, Brazil

Background and Objective: It is known that climatic changes and the urban mobility are increasing the numbers of dengue cases. In 2019, were registered 5,2 million new cases, and World Health Organization aim to reduce mortality caused by this disease until 2030. Dengue is the main arbovirolosis disease, being a viral infection transmitted to human through by infected mosquitoes, mainly Aedes Aegypti. In the last 12 years, were notificaded 16,942538 cases in Brazil, whereupon São Paulo is the most prevalent state (26.9%). The objective of the study was to establish epidemiologic profile of dengue in the State of São Paulo/Brazil, in the last 12 years. **methods** This is an observational, descriptive, cross-sectional, and retrospective study, which was carried out through the analysis of secondary data collected from the National System of Notification Appeals (SINAN) and from SUS Computer Department (DATASUS).

Results: The total number of reported cases was 4,558,369 and 2015 was the year with the highest cases (1,033,070). The cases were predominant in the female sex (53.7%), white people (54.4%), high school completed (16.1%) and clinical and epidemiological criteria of confirmation (63.8%). Concerning hospitalization rates, there was a limited necessity of admissions (2.2%), as well as few deaths due to the notified disease (1557). **Conclusions:** There was a significant growth in the number of dengue cases in Brazil from 2019, during pandemic COVID-19, which represents a public health problem. Health promotion and prevention actions should be intensified in primary health care.

T05 - Ce.I.R.S.A., Torino, Italy, ⁸Prevention, Veterinary Public Health and

Food Safety Department, Public Health & Welfare Directorate, Piemonte Region, Italy, ⁹Department of Life Sciences and Systems Biology, University of Torino, Italy

Background and Objective: Enteric viruses are among the main causes of water-borne infectious diseases, therefore their monitoring in waters is crucial for public health. In the present work, financed by the Piemonte Region, the occurrence of seven enteric viruses was monitored in urban sewages of two Wastewater Treatment Plants (WWTP) and in livestock sewages of three farms (beef cattle, dairy cattle and pigs).

Methods: The nucleic acids of 16 influent and effluent samples of the two WWTPs were concentrated and extracted using eGeneUP® with magnetic silica, while the nucleic acids of 12 livestock manure samples were extracted using the AllPrep® PowerViral® DNA/RNA. The presence of enteroviruses (EV), adenoviruses (AdV), noroviruses (NoVs) GI/GII, hepatitis A virus (HAV), hepatitis E virus (HEV) and rotavirus (RV) was evaluated by PCR.

Results: All municipal wastewater samples (100%) tested positive for at least one viral pathogen. 93.7% of samples tested positive for RV (93.7%), followed by NoV GII (68.7%), and AdV (43.7%). High percentages of positive samples were also detected for EV, HEV and NoV GI (37.5%), while HAV was not identified. For all viruses, except RV, the percentage of positivity in the effluent was lower than in the influent of the two WWTPs. 91.6% of the livestock manure samples tested positive for at least one viral pathogen with RV being the most present pathogen (83.3%). HAV, HEV, EV, AdV, and NoV GI were detected in 33.3%, 33.3%, 25%, 8.3%, and 8.3% of the samples, conversely NoV GII was not found.

Conclusions: Since WWTP effluents are discharged in surface waters and livestock sewages can be reused as soil fertilisers, the results highlighted the need to consider and manage these matrices as potential sources of virus spread in the environment in order to protect humans in a one-health approach.

Public health impact of new sustainable agronomic practices: the TOMRES project

Elisabetta Carraro¹, Silvia Bonetta², Veronica Porro¹, Elisa Gasparro¹, Lisa Richiardi¹, Cristina Pignata³

¹Department of Public Health and Pediatrics, University of Turin, Italy,

²Department of Life Sciences and Systems Biology, University of Turin, Italy,

³Dept. of Public Health and Pediatrics, University of Turin, Italy

Background and Objective: Agricultural crops require high volumes of water and fertilizers. Nowadays, water resources are scarce, also for climate changes, and fertiliser production requires large amounts of non-renewable resources such as phosphorus. The TOMRES project (Horizon 2020, n. 727929) involved 25 partners from 10 European countries with the aim of increasing tomato tolerance to the combination of water and nutritional stress. Sustainable management strategies suitable for water and nutrients absorption from soil were tested and optimised, including fertilisation, irrigation techniques, symbiotic microorganisms and biostimulants use. With the purpose of assessing the effects on Public Health, the evaluation of the hygiene and sanitary impact of the new cultivation method was investigated.

Methods: Microbiological indicators and pathogens, ecotoxicological indicators, pesticides and heavy metals contamination were analysed on soil samples in relation to the agronomic techniques applied in the project trials. To evaluate the hygiene and sanitary impact a statistical comparison of the Results obtained in soil samples between pre- and post-cultivation (t-test) and among the different cultivation strategies applied in each trial (ANOVA) was carried out.

Results: The overall Results showed that the reduction of water and fertiliser use leads to a reduction of bioavailable heavy metals, microbiological contamination and ecotoxicity. However, the results underlined that the use of these sustainable agronomic practices should be managed with particular attention in areas where there may be over-fertilization due to previous agricultural activities because of the risk of toxic substances mobilization in the soil.

Conclusions: The agricultural practices evaluated in the TOMRES project are promising as they limit heavy metals mobility, microbiological contamination and ecotoxicity. So, resilient tomato cultivars could grow using new crop management techniques with a reduction of water and nutrient consumption that is a fundamental goal for linking the growth of the world population with climate changes.

Climate change and wastewater treatment: human pathogens and microbiological indicators in Alpine aquatic environments

Silvia Bonetta¹, Silvia Bonetta¹, Manuela Macri¹, Marta Catozzo¹, Silvia Bertolotti¹, Anna Marino¹, Elisa Falasco¹, Marco Minella², Francesca Bona¹, Stefano Fenoglio¹

¹Department of Life Sciences and Systems Biology, University of Turin, Italy,

²Department of Chemistry, University of Turin, Italy

Background and Objective: Recent research highlighted the negative impact that climate change has on social and environmental factors that determine human health, such as availability and quality of water resources. In particular Alpine rivers, frequently utilized for different human activities (e.g. drinking and irrigation), are more altered by climatic change showing a general flow rate reduction that can affect water quality. In fact, during the more frequent periods of drought, emissions from anthropogenic sources such as wastewater treatment plant (WWTP) discharges are less diluted determining an increase in the concentrations of pathogenic microorganisms. The aim of this study is to evaluate the wastewater discharge effect on spreading of human pathogens in Alpine rivers in relationship to flow rate reduction.

Methods: Samples upstream (U), downstream (D) and at discharge (W) of WWTPs in three Alpine streams were collected monthly for one year. Parameters investigated are: coliforms, enterococci and *Escherichia coli* quantification using Quanti-Tray™ 2000 (IDEXX Laboratories), *Clostridium perfringens* spores enumeration using membrane filtration method, presence/absence of *Salmonella* spp. and verocytotoxin-producing *E. coli* (VTEC) by PCR. Moreover, also ecological, chemical and hydrological aspects are investigated.

Results: Discharge samples (W) showed high contamination by the different indicators, but the effect of WWTP is mainly evidenced in one of the investigated rivers which shows an increase respect to U samples. *Salmonella* spp. was present in all rivers investigated, but similarly among U and D samples except for one river, indicating other contamination sources. VTEC presence seems to be not related to WWTP discharge.

Conclusions: The results obtained so far indicate that WWTP effect is detectable but strongly related to the sampling site underlining the need to monitor the microbiological contamination in river impacted by climatic change reducing human pathogen circulation and the possible indirect effect on human health.

Epidemiological update of human cases of Toscana Virus infections in the Emilia-Romagna region in the period 2010-2022

Daniela Azzalini¹, Elena Righi¹, Giuseppe Diegoli², Giulio Matteo², Andrea Mattivi², Gian Belloli², Giovanna Mattei²

¹Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, ²Regional Health Authority, Emilia-Romagna Region, Bologna, Italy

Background and Objective: Toscana virus (TOSV) infection often occurs asymptotically or with mild symptoms (asthenia, fever, headache) but it can also generate neurological clinical pictures (meningitis, encephalitis). This epidemiological update describes the trend of human confirmed cases of tosv in the period 2010-2022 in Emilia-Romagna region and the main characteristics of the population involved.

Methods: The elaborations refer to the notifications of infectious diseases, on the regional web-based system "Surveillance of Infectious Diseases" (SMI), provided by ministerial decree 15/12/90, based on the Arboviroses surveillance system (dgr 531/2022) of the 2022 Emilia-Romagna regional plan for the surveillance and control of Arboviroses (PSCA).

Results: In the period 2010-2022, 568 confirmed cases of TOSV were notified. The trend of reports of TOSV infections was variable: a minimum number of cases in 2011 (15 cases) and two peaks in 2013 and 2022 (88 cases and 109 cases, respectively). During the period 2010-2021 we observed a peak of cases in August, in 2022 the peak was observed one month later. In all years, TOSV infection was prevalent in males. In terms of incidence the most affected age group was 25-44 years followed by 45-64 years and over 65. Referring to 2022, we observed a wide overlap between the areas where more human TOSV infections were notified and the areas where more sandflies were caught. During the period 2013-2022 TOSV infections manifested mainly with meningitis, except in 2018 when we recorded more cases of encephalitis.

Conclusions: TOSV infections represent an emerging public health concern. The aim of the PSCA and the Emilia-Romagna region surveillance system is to rapidly identify TOSV infections' cases and to stimulate behaviors aimed at individual protection and prevention of the vector's spread in order to correctly invest future resources.

Exposure to neighbourhood greenness and hypertension in adults: a cohort study in Taiwan

Yi Zeng¹, Marc Chong¹, Xiang Lao¹

¹Jockey Club School of Public Health and Primary Care, The Chinese University of Hong Kong, Hong Kong, China

Background and Objective: There is limited information on the health effects of long-term exposure to neighborhood greenness in a longitudinal setting, especially in the Asian area with high population densities. This study aims to investigate the association between long-term exposure to neighborhood greenness and hypertension among adults from Taiwan.

Methods: We selected 125537 participants (≥ 18 years of age) without hypertension from Taiwan who joined the standard medical examination program between 2001 and 2016. Neighborhood greenness was estimated by normalized difference vegetation index (NDVI) derived from satellite images at a resolution of 250 m². The two-year average of NDVI within a 500m buffer around participants residences was calculated. A time-varying Cox regression model was used to investigate the association between greenness and incident hypertension. Mediation analyses were performed to investigate whether the association was explained by air pollution, physical exercise, and body mass index (BMI).

Results: Compared to participants living in the areas with the first quartile of neighborhood greenness, participants living in the areas with the second, third, and fourth quartiles of neighborhood greenness were associated with a lower risk of hypertension, with a hazard ratio (HR) (95% confidence intervals) of 0.95 (0.91, 1.00), 0.95 (0.90, 0.99), and 0.93 (0.88, 0.97), respectively. Each 0.1-unit increase in NDVI was associated with a 24% lower risk of developing hypertension (HR: 0.76, 95%CI: 0.66, 0.87). The associations were stronger among males and individuals with higher education levels. BMI slightly mediated the association, but there was no evidence of mediating effects of air pollution and physical exercise.

Conclusions: Our findings suggest the protective effects of neighborhood greenness on hypertension development, especially in males and well-educated persons. Our findings reinforced the importance of greenness for the neighborhood environment.

Biomonitoring the estrogenic effect of wastewaters: role of extraction phase and assay type

Marta Gea¹, Tiziana Schilirò², Federica Spina³, Roberta Revello², Giovanna Varese³

¹Department of Public Health and Pediatrics, University of Turin, Turin, Italy, ²Department of Public Health and Pediatrics, University of Turin, Italy, ³Department of Life Science and Systems Biology, University of Turin, Italy

Background and Objective: Endocrine disruptors, emerging contaminants of concern, are mainly spread in the environment through effluents of wastewater treatment plants (WWTPs), so an efficient monitoring of effluents is needed. Biological monitoring through estrogenic activity assays has been suggested to improve water quality assessment. This monitoring can evaluate the overall endocrine activity, considering all chemicals with the same mode of action. However, it could be influenced by many factors. This study compared the estrogenic activity of wastewaters extracted with different extraction phases and analyzed with different assays to establish whether phase and/or assay may affect monitoring results.

Methods: The effluents of six Italian WWTPs were collected in four seasonal samplings and extracted using two phases (HLB, C18). The extracts were tested using gene reporter assay on mammalian cells and yeast estrogen screen assay (YES). To assess whether the estrogenic activity posed an acceptable risk, Results of the cumulative effluent (discharged in surface waters) were compared with safe estrogenic levels reported in literature.

Results: The estrogenic activity of effluents extracted with HLB was significantly different from the estrogenic activity of effluents extracted with C18, showing that phase type can affect monitoring results. Moreover, the Results were also affected by the assay type. Using the gene reporter assay the estrogenic activity was generally higher than using YES, confirming that mammalian cell-based assays are more sensitive than yeast-based assays. Finally, gene reporter data suggested that estrogenic activity of the cumulative effluent might pose a risk to the receiving waters, while YES data suggested that it does not represent an environmental threat.

Conclusions: This study highlighted the need to define a standardized approach to assess the endocrine disrupting potential of waters and provided data that could be useful to choose the most appropriate extraction phase and assay to safeguard environment, thus protecting human health.

Evaluation of healthy housing: a strategy to improve environmental health

Laurent Gerbaud^{1,2,3}, Aurélien Alfaré⁴, Anna Shojijimaeva⁵, Aline Bonnet⁶

¹Institut Pascal, CHU Clermont-Ferrand, SIGMA Clermont, Université Clermont Auvergne, France, ²CNRS F-63000 Clermont-Ferrand, France, ³Service Santé Universitaire - UCA, France xxxUniversité Clermont Auvergne, CHU de Clermont-Ferrand, Inserm, Clermont-Ferrand, France, ⁴REVELEO, Paris, France, ⁵Communauté de communes de Brioude, Brioude, France, ⁶Centre Hospitalier de Brioude, Brioude, France

Background and Objective: Environmental quality of housing is a part of health protection. It combines reduced exposures to pollutions and access to available resources for protection and care services. In France, many local authorities lack of financing capacities or political will to improve housing, except for tourism (hotels, etc.) a key for local economy development. We developed a tool (Reveleo) able to check the environmental quality of the housing and applied it to tourism facilities (hotels, guest houses...) to check the feasibility and acceptability of both tourism holders and local authorities.

Methods: Reveleo combines open sources data (ie exposure to air polluting, noise,...) from French Governmental agencies and a questionnaire dedicated to the quality of buildings and close environment. We have tailored the questionnaire so that to clarify health issues and make it fillable by any tourism holder. We tested it, in an urban and rural area of 17000 inhabitants and also checked how it could match the question of tourism development policies.

Results: Among the 18 tourism holders, 10 answered. Hotel holders did not answer mainly due to the lack of employees they had to face. All the questionnaires were fulfilled, with 78% of the items answered. The scoring for quality of environmental housing goes from 18,6 to 100 (the best possible score). We presented the results to the technical and political staffs of the area which decided to continue the experiment and were able to see the kind of actions they can take. **Conclusions:** We need to make some improvement to our tool, for answers difficult to get. But, for now, its feasibility and acceptability are good, and there are good hopes that it will help improve or build better healthy environment policies.

The association between lead exposure and crime: a systematic review

Maria Talayero Schettino¹, C. Robbins¹, Maria Talayero Schettino¹, C. Robbins¹, Carlos Santos Burgoa¹, Emily Smith¹

¹The George Washington University Milken Institute School of Public Health, United States

Background and Objective: Prior research has demonstrated an association between lead exposure and criminal behavior at the population-level, however studies exploring the effect of lead exposure on criminal behavior at the individual-level have not been reviewed systematically. The intent of this study is to complete a systematic review of all studies assessing individual-level exposures to lead and the outcomes of crime and antisocial behavior traits.

Methods: We included peer reviewed studies that were published prior to August 2022 and were classified as cohort, cross-sectional, or case-control. Studies measuring the outcomes of crime, delinquency, violence, or aggression were included. The following databases were searched using a standardized search strategy: ProQuest Environmental Science Database, PubMed, ToxNet and the Public Affairs Information Service (PAIS).

Results: Seventeen manuscripts met our inclusion criteria. Blood lead was measured in 14 studies, bone lead in 3 studies, and dentine lead levels in 1 study. This systematic review identified a consistent and statistically significant association between exposure to lead in the prenatal and 5 - 6 y period and later delinquent and criminal behavior, with increasing blood lead concentrations in childhood prospectively associated with later arrests and convictions in six studies.

Conclusion: There is limited data at the individual level on the effects of prenatal or childhood lead exposure and later criminal behavior and more evidence is necessary to evaluate the magnitude of the associations seen in this review. Our review, in conjunction with the available biological evidence, suggests that an excess risk for criminal behavior in adulthood exists when an individual is exposed to lead in utero or in the early years of childhood.

The global diet quality score's correlation with the EAT-Lancet

sustainable dietary guidelines in Brazil

Marina Norde¹, Leandro T Cacau², Sabri Bromage³, Dirce M L Marchioni², Ana Vasques², Aline M de Carvalho², Megan Deitchler⁴, Licio A Velloso⁵, Edward Giovannucci⁶, Bruno Geloneze⁵

¹University of Campinas, Obesity and Comorbidities Research Center, University of Campinas, Campinas, SP, Brazil, ²School of Public Health, University of Sao Paulo, Sao Paulo, SP, Brazil, ³Institute of Nutrition, Mahidol University, ⁴Intake-Center for Dietary Assessment, FHI Solutions Washington, DC, United States, ⁵Obesity and Comorbidity Research Center, University of Campinas, Campinas, SP, Brazil, ⁶Harvard T. H. Chan School of Public Health, Harvard University, Boston, MA, United States

Background and objective: The world faces a global syndemic, in which diet is an important risk factor. The Global Diet Quality Score (GDQS) is a simple, timely and low-burden tool to track the contribution of diet to undernutrition and overnutrition globally. The Planetary Health Diet Index (PHDI) is an indicator of adherence to the EAT-Lancet Commission sustainable dietary guidelines. The present study aimed at investigating the correlation between the GDQS and PHDI in the Brazilian diet, to highlight concordances between them and shed light into the GDQS' potential as a sustainable diet metric.

Methods: The study was conducted in a nationally representative sample of 44,744 individuals aging ≥ 10 from the Household Budget Survey of Brazil, in which dietary data collection took place between 2017-2018, by trained interviewers using two 24-hour recalls per participant. The GDQS and PHDI were scored from the two 24-hour recall means of intake. Spearman's correlation coefficient between the GDQS and PHDI was estimated for the whole sample and across sex, age, and income strata.

Results: The correlation coefficient between the GDQS and PHDI was 0.21 ($p < 0.001$), varying from 0.17 to 0.29 by strata. Women, elderly individuals, and the highest income strata had the strongest correlation between metrics (0.23, 0.26, and 0.29, respectively). Classification of food components into healthy, unhealthy in excessive amounts or unhealthy was discordant between metrics for vegetable oils, fish and seafood, low fat dairy, eggs, poultry and substitutes, red meat, and deep orange tubers.

Conclusion: The GDQS is positively correlated with the PHDI in Brazil. Sources of discordances between metrics notably rely on the definitions of optimum intake of animal products, which should be subject to further evaluation.

Acknowledgements: To the Sao Paulo Research Foundation (FAPESP) for funding our work (grant 2013/07607-8; 2022/08172-4), and Prof. Walter Willett (Harvard University) for the contribution.

Situation analysis of drinking water quality and sanitary conditions in small scale water supply systems in rural areas in Serbia

Dragana Jovanovic¹, Vesna Karadzic¹, Milena Vasic²

¹Institute of Public Health of Serbia "Dr Milan Jovanovic Batut", Dr Subotica 5, Serbia, ²Faculty of Dentistry Pancevo, Serbia, "Zarka Zrenjanina 179, 26000 Pancevo", Serbia

Background and objective: Small scale water supply systems (SSWS) in rural areas in Serbia are facing with many challenges in providing safe drinking water to rural population, likewise in entire pan-European region. This was the first comprehensive situation analysis aimed at assessing the drinking water quality and the sanitary condition conducted in Serbia. Drinking-water quality monitoring in rural areas is less enforced in the Monitoring programme on drinking water quality in Serbia, hindering a comprehensive understanding and systematic assessment of the situation of SSWS, as well as the effective planning and implementation of adequate improvement measures at national and local levels.

Methods: This national survey was undertaken in rural areas of the Republic of Serbia in 2016 and on the basis of the WHO rapid assessment methodology. The total number 1,136 of small piped systems were inspected, using sanitary inspection forms for each water technologies and in total 1,168 of water samples were taken and analyzed for E. coli and selected physico-chemical parameters against national standards for drinking water quality.

Results: Only 66.9% of water samples taken from SSWS were in compliance with the National standard regarding E.coli, 55.6% were in compliance regarding physico-chemical characteristics, while overall compliance was 36.9%. The most prevalent identified sanitary risks were: absence of fence in 73%, managing by unqualified personnel in 70%, close vicinity to the source of contamination in 64%, and unsatisfactory technical conditions in 55%.

Conclusion: This study pointed to the high health risk for rural population in Serbia as a consequence of microbiological contamination of drinking water from rural

SSWS and revealed poor sanitary conditions. It is crucial to develop an action plan at national and local level for the improvement of the situation on small-scale water supply systems in rural areas.

Sustainable and green hospital project in the province of Padua, Italy

Emanuela Zilli¹, Suada Tikvina², Guido Di Gregorio³, Davide Bonaldo³, Antonella Ruffatto³, Marzia Serafini⁴, Luisa Fontana⁴, Tommaso Caputo⁴

¹Azienda ULSS 6 Euganea, Hospital Direction, Hospital of Cittadella, ULSS 6 Euganea, Padua, Italy, Via Casa di Ricovero 40, Cittadella (Padua), Italy,

²Department of Cardiac, Thoracic, Vascular Sciences and Public Health,

University of Padua, Italy, ³Azienda ULSS 6 Euganea, Department of

Reanimation and Intensive therapy, Hospital of Cittadella, ULSS 6 Euganea, Padua, Italy, Via Casa di Ricovero 40, Cittadella (Padua), Italy, ⁴Azienda

ULSS 6 Euganea, Quality manager, ULSS 6 Euganea, Padua, Italy

Background and Objective: Cittadella's Hospital in the province of Padua, currently under construction, offers 400 beds. Given the changes in the population and environmental demand, more functional and secure areas of healthcare were needed. The new structure is set to be completed in 2026 introducing interesting features in order to project a safe, modern and green hospital concept.

Methods: An innovative approach was used in the design of this new structure, dedicating the utmost attention to environmental sustainability, green materials, insertion in the urban and social context, enhancement of existing buildings, functional organization of the treatment areas and circulation zones, accessibility for all people, and humanization of the hospital experience.

Results: The interior design was inspired by the external environment (sun movement, climate, landscape). Areas of care and diagnostic-treatment paths were reorganized according to guidelines set during the pandemic. There is an extensive use of renewable energy (solar panels, geothermal heat pumps, photovoltaic-battery hybrid system), a 4th-generation heating system and practical and easy to sanitize surfaces were designed. There is particular focus on the quality of the staff areas, which include spaces dedicated to psycho-physical well-being (relax points, yoga gym), and areas to encourage collaborative work (study rooms, centralized conference room). Outdoor recreational spaces and gardens for music and watercolor therapy were included and a Tai-chi gym is dedicated to oncology patients. Integration in the urban and social context is emphasized through window placement towards the gardens (maternal-infant, mental health and rehabilitation wards) and the city medieval walls.

Conclusion: Green healthcare provides benefits to patients, healthcare professionals and the environment. The use of renewable energy, a fourth-generation heating system, safety in air quality and ventilation, easily sanitized and maintainable surfaces and green materials contribute to the reduction of emissions into the atmosphere for a more sustainable future on the planet.

Spacial injustice: the imbalance between supply and demand for Ecosystem Services

Nausicaa Berselli¹, Maria Gatti², Claudia de Luca³

¹University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Via Campi 287, 41125, Modena, Italy,

²Ausl Modena, Epidemiology and Risk Communication Unit, Department of Public Health, Strada Martiniana 21, 41126, Modena, Italy, ³Alma Mater Studiorum University of Bologna, Department of Architecture, Viale del Risorgimento 2, 40136, Bologna, Italy

Background and Objective: Ecosystem Services (ES) are benefits that natural systems generate and contribute to human well-being. The study intends to map the supply and demand of an important ES for climate regulation, the cooling given by green infrastructures, in the province of Modena (northern Italy), in order to identify situations of spatial injustice.

Methods: The cooling capacity given by green infrastructures (supply of ES) was calculated using the InVEST (Integrated Valuation of Ecosystem Services and Tradeoff) software, which calculates the heat mitigation index based on shading, evapotranspiration at albedo and distance from the green infrastructure. The characteristics of vulnerability to heat (demand of ES) considered were age over 80 or under 14, condition of fragility in old age, status of foreigner and low per capita income, obtained through demographic registers or surveillance systems. The cooling capacity given by green infrastructures and the heat vulnerability characteristics were achieved for each municipality in the province of Modena, thus building maps of the supply and demand of the ES.

Results: The study shows the presence of a lower cooling capacity and, at the same time, a greater concentration of subjects more vulnerable to high temperatures, in the city center and in the flat municipalities, especially the most industrialized. The comparison between the supply and demand maps of ES highlights a situation of social injustice, in which the greatest demand is present in places where the climatic mitigation given by greenery is minimal and where summer heat waves occur.

Conclusion: This study is a guide for policy makers for a correct urban redistribution and the implementation of nature-based solutions in areas where the demand is higher, using small-scale solutions (e.g. vertical greenery, green roofs) where there is no possibility to increase public green spaces.

Evaluation of indoor air quality and its architectural, environmental, and occupational determinants in a primary health care center - a research protocol

Francisca Pulido Valente¹, Diogo Cortes Lopes¹, Dinis Loyens¹, Ana Baptista¹, Francisco Barcelos¹, Maria Borges¹

¹Public Health Unit of Amadora Portugal

Background and Objectives: Indoor air quality (IAQ) is a significant determinant of health and well-being. Most people spend 90% of their time inside, so maintaining a high level of IAQ is essential. As primary healthcare facilities serve large populations and have many employees, it is especially critical to characterise their IAQ. However, scant research has been done on this topic, and there is no specific legislation regarding IAQ in these locals. In this study protocol, it is proposed to determine what factors contribute to poor IAQ at Amadora Primary Health Care Center (PHCC).

Methods: Using the environmental monitor EVM-7, PM2.5, PM10, CO2, total volatile organic compounds, temperature, and relative humidity will be measured in the treatment rooms, waiting rooms, and consultation rooms of the functional units of the PHCC of Amadora. Buildings and rooms will be characterised according to their architectural features, surroundings, and occupation, utilising the form explicitly developed for this purpose. IAQ will be described by referring to Portuguese IAQ legislation. Using the statistical analysis software Stata® 17, multilevel regression models will identify statistically significant associations between the variables.

Results: Results are expected to provide insight into how buildings, facilities, and occupant behaviour affect IAQ at PHCC of Amadora. Additionally, they will enable the development of recommendations designed to protect patients and workers health, quality of life, and well-being.

Conclusion: IAQ in PHCC has not been sufficiently studied, and research has been primarily focused on the hospital context and microbiological parameters. This protocol will identify architectural infrastructure and human occupation as determinants of poor IAQ in PHCCs and stimulate discussion on the need to revise Portugal's air quality legislation. A collaborative approach is emphasised between the public health sector and engineering, architectural, and occupational health.

An ecological study on climate vulnerability and health in India- case for an improved risk index

Jaya Kshatri¹, Kavitha Ak¹, Sanghamitra Pati¹

¹Indian Council of Medical Research (ICMR) "ICMR RMRC Nalco Square Chandrasekharpur, Bhubaneswar" India

Background and Objective: Climate change has the most direct and immediate effect on a population's health, highlighting the need for assessing vulnerability of communities towards this effect. This study examines the relationship between common health outcomes and a 'climate vulnerability index (VI)' used in India to assess its predictive capability.

Methods: This was an ecological study using districts of India the unit of analysis. Secondary data of four nationally representative datasets obtained from the National Data Analytics Platform was used in this study: fifth round of the National Family Health Survey (NFHS-5), National Health Missions Health Management Information System (HMIS), estimates of district vulnerability, and the latest Census of India. We used some common health outcomes available with these datasets to estimate their correlation with the districts Vulnerability Index (VI), which was the exposure of interest.

Results: The VI of the districts was between 0.34 and 0.75. Among them 222 districts were classified as Very highly and highly vulnerable (VI: 0.59-0.75), 258 as moderately vulnerable (VI: 0.51- 0.59) and 132 districts as low or very low vulnerable (VI: 0.34 – 0.51). There was a statistically significant correlation

between VI and prevalence of obstetric complications including gestational diabetes mellitus, still births, spontaneous abortions as well as the incidence of childhood pneumonia, asthma, and sepsis. However, the VI had few health parameters in its construction and is not suitable for predicting health related outcomes.

Conclusion: The vulnerability index used in India to classify districts did not significantly or consistently correlate with measures of population health, making it unsuitable for use in health impact assessments.

Popul. Med. 2023;5(Supplement):A221

DOI: 10.18332/popmed/164098

Effects of mud-therapy on pain, function and quality of life in patients with rheumatic and dermatologic diseases: A systematic review and meta-analysis

Maria Facchini¹, Stefania Paduano¹, Francesco Venturelli², Michele Antonelli³, Valentina Mingrone¹, Isabella Marchesi¹, Federica Valeriani⁴, Maria Bassi⁵, Annalisa Bargellini¹

¹Department of Biomedical, Metabolic and Neural Sciences, Section of Public Health, University of Modena and Reggio Emilia, Italy, ²Epidemiology Unit, Azienda USL-IRCCS di Reggio Emilia, Italy, ³Department of Public Health, Azienda USL-IRCCS Reggio Emilia, Italy, ⁴Department of Movement, Human and Health Sciences, Public Health Unit, University of Rome 'Foro Italico', Italy, ⁵Medical library, Azienda USL-IRCCS di Reggio Emilia, Italy

Background and Objective: Various studies examined mud-therapy in the last twenty years, but mechanisms of action of these non-pharmacological treatments (mudpack or mud-bath) are still almost unknown and it is difficult to establish the efficacy of mud-therapy approach.

The aim of this meta-analysis is to offer an update of the existing literature on the efficacy of mud-therapy in rheumatic and dermatologic diseases.

Methods: Electronic bibliographic databases (PubMed, Embase, Medline, Central, Scopus, Pedro) were screened for articles published in English or Italian from January 2000. Studies that compared mud-therapy (alone or combined with drug or thermal or physical therapies) to any other intervention or to no intervention in adults (≥18 years) with rheumatic and dermatologic diseases were selected.

The main outcomes were pain, function, quality of life, adverse events. Randomized clinical trials, non-randomized trials, and comparative cohort (prospective and retrospective) were eligible if they assessed at least one main outcome. Non comparative case series and case reports were included for safety outcome only. For categorical outcomes, the effect measure is synthesized calculating Risk Ratio and Risk Difference and for continuous outcomes calculating Mean Difference or standardized Mean Difference. A meta-analysis is performed based on heterogeneity between included studies, assessed statistically.

Results: Of the 3332 articles screened after duplicates removing, 76 studies satisfied the eligibility criteria and were included. Preliminary analysis showed an improvement in 29/35 (82.9%) articles evaluating quality of life in adults treated with mud-therapy; this improvement was reported as significant in 54.3% (19/35). Similar evidence was found in studies evaluating function (36/48, 75.0% of improvement; 28/48, 58.3% of significant improvement) and pain (37/46, 80.4%; 31/46, 67.4%, respectively). Meta-analysis is ongoing.

Conclusions: These preliminary results suggest a therapeutic effect of mud-therapy for rheumatic and dermatologic diseases. Meta-analysis is necessary in order to reach definitive conclusions on the current evidence.

DOI: 10.18332/popmed/164231

Gender differences in the Effects of Urban Greenness on Cardiovascular Disease Outcomes

Alessandro Bianconi¹, Angela Coa¹, Giulia Longo¹, Matteo Fiore¹, Davide Gori¹

¹University of Bologna Department of Biomedical and Neuromotor Sciences Italy

Background and objectives: Cities are expected to host more than two third of the world population by the half of XXI century. Some aspects of the built environment in the urban context, such as residential greenness, may impact citizens' health. Many studies highlighted how urban greenness (UG) is correlated to better cardiovascular health. Built environment is experienced differently by genders. Aspects of greenness design, such as visibility and maintenance state, are more impactful on perceived safety on women than in men. The aim of this study is to assess if the effects of UG on cardiovascular diseases (CVD) is the same in both men and women.

Methods: The PRISMA Statement guidelines were followed while conducting this systematic review. A systematic search of the current literature was performed

through Scopus and PubMed databases. Primary research studies analyzing associations between residential UG exposure measures and CVD outcomes were searched. Only study presenting stratified analyses by gender were finally included.

Results: Eight studies that performed stratified analyses by gender were found. Five studies found a protective effect of UG exposure on CVD outcomes that was statistically significant only in men. Two studies found no statistically significant effect of UG on cardiovascular outcomes in both male and female. One study highlighted an inverse correlation between residential UG and CVD morbidity in both men and women.

Conclusion: This study suggests the presence of underlying gender-specific mediators on UG impacts on CVD outcomes. Since the small number of literature examples of gender-stratified impacts assessment of UG on cardiovascular health, further studies are needed to understand the explanatory mechanisms involved.

Popul. Med. 2023;5(Supplement):A223

DOI: 10.18332/popmed/164411

Heatwaves perceived impacts and adaptive behaviours - results of a cross-sectional study in pakistan

Farman Ullah¹, Francesco Barone-Adesi², Ives Hubloue³, Luca Ragazzoni¹, Martina Valente²

¹Università del Piemonte Orientale CRIMEDIM - Center for Research and Training in Disaster Medicine, Humanitarian Aid, and Global Health - Università del Piemonte Orientale (UPO), 28100 Novara, Italy I Piano, Via Bernardino Lanino, 1, 28100 Novara NO Italy, ²Università del Piemonte Orientale, ³Vrije Universiteit Brussel (VUB), Brussels, Belgium Research Group on Emergency and Disaster Medicine (REGEDIM), Brussels, Belgium

The frequency and severity of heatwaves have been on the rise, thus seriously posing a great challenge to human health and societal well-being. To find out how people perceive impacts and adapt to heatwaves, this cross-sectional study was carried out across Pakistan.

Data was collected using a standardized questionnaire using Likert Scale technique. Heatwaves perceived impacts were measured using a total of five items using a scale i.e., Not at all "1", Less likely "2", Fairly "3", Very Much "4", A great deal "5". Whereas individual adaptation was measured using a total of 14 statements using a five-point Likert scale of Never "1", Rarely "2", Sometimes "3", Very Often "4", and Always "5" respectively. Demographic information included age, gender, marital status, education, employment, income, ethnicity, living arrangements and type of residence.

A total of 698 responses were received with the majority belonging to urban areas (60.64%) compared to rural areas (39.36%); with most of the respondents being male (71.14%) compared to female (28.86%). Majority of the respondents were from ethnic background "Pashtun" (34.99%) followed by Punjabis (17.78%), other ethnicities (17.20%), Urdu Speakers (16.47%) and Sindhi and Baluchi (13.56%).

Results for perceived impacts suggest extreme impacts in terms of a higher perceived negative personal health impacts, increased perceived negative health impacts on relatives, extreme worry about overall heatwaves impacts in general, high perceived likelihood of heatwaves events and high perceived negative consequences of heatwaves in Pakistan.

Respondents' individual adaptive behaviours were measured using fourteen statements, for example "Use an umbrella/cloth when walking outside" (Cronbach's alpha=0.91). The total individual adaptive behaviour score was then dichotomized into low (14-43) and high (44-70) at "midpoint". The study results can play an important role in targeting certain activities at the grassroots level keeping in mind the vulnerable situation of different ethnic groups.

Overcoming the challenges of problem identification in complex systems of urban health

Geoff Bates¹, Daniel Black²

¹Institute for Policy Research, University of Bath, Bath, United Kingdom, ²Bristol Medical School, University of Bristol, United Kingdom

Brief outline of the overall workshop: Global public health challenges such as climate change, non-communicable diseases, and health inequalities are driven by innumerable interacting factors. Tackling these challenges is increasingly recognised as requiring new and large teams from a wide range of disciplines and sectors spanning large and complex systems, who must identify and agree the root causes of problems to target. The challenge of problem identification becomes substantially greater in complex systems, and for large teams with heterogeneous backgrounds, expectations, and priorities. This workshop looks at how large research teams can identify and develop shared understandings of problem areas

in complex systems, with a view to fostering effective collaboration with critical, targeted stakeholders. Through presentations introducing key concepts followed by structured small group work and whole group debate, participants will hear and contribute to Discussions on problem identification within large research teams and approaches to targeted stakeholder engagement in complex systems. The workshop draws on the presenters' critical reflections from TRUUD (Tackling the Root Cause Upstream of Unhealthy Urban Development), a five-year collaboration between five universities in the United Kingdom and their partners in industry, government, and the public.

Specific Aims/ Objectives and Component Parts: This workshop aims to develop knowledge and ideas that can support large teams to develop shared conceptualisations of complex public health problems. Key objectives are i) to share knowledge about the challenges of problem identification in large research teams and understand why this is critical for tackling complex public health challenges, ii) to define what constitutes good co-production of problem identification with stakeholders in a complex system, and iii) to improve knowledge of the processes and tools that can support large teams to develop shared understandings on these issues. The workshop will include a mixture of presentations, audience questions, and structured discussions in small groups. Firstly, facilitators will share their learnings from the TRUUD project on problem identification and developing shared understandings in inter- or trans-disciplinary teams, and stakeholder engagement in complex systems. Secondly, workshop attendees will be invited to ask questions to the facilitators and to share their reflections on key concepts. Thirdly, attendees will be divided into small groups to debate issues in engaging the wide range of stakeholders relevant to research on complex public health problems, including how to identify stakeholders and when engagement should occur. The session will conclude with a final plenary session where groups will feed back their ideas and we will identify areas of consensus for approaches to stakeholder engagement in a complex system.

Key questions that the workshop will seek to address: The workshop will explore the overall question 'How can large research teams conceptualise and develop shared understandings of complex health problems to support intervention development?'. Sub-questions include: 1. How can researchers from multiple disciplines develop shared understandings of complex problem spaces? 2. How can stakeholder engagement be managed to help identify and understand problem spaces in complex systems? 3. What tools, methods, and processes help teams to coalesce around specific problems in complex systems?

How can the public health community support litigation to protect public health in the context of climate change and other environmental threats to health?

Farhang Tahzib¹, Stephen Holgate², Brigit Toebes³, David Patterson⁴

¹UK Faculty of Public Health, United Kingdom, ²University of Southampton School of Medicine, United Kingdom, ³Aletta Jacob School of Public Health, Netherlands, ⁴Groningen Centre for Health Law, The Netherlands

Outline: Climate change and environmental health are important cross-cutting issues to address within the public health sector. Encouraged by wins on asbestos and against big tobacco, the public health community and environmental advocates are turning to litigation to sue governments and private sector interests for public health harms from environmental pollution and climate change. Climate litigation can be supported using essential public health functions while simultaneously raising awareness about the health impacts on planetary health. Increasingly, climate cases submitted to courts include a focus on health. Yet there remains a lack of awareness and training among the public health community. In October 2021 the European public health association (EUPHA-law) co-hosted a webinar on public health, climate change and strategic litigation which highlighted how strategic partnerships between public health practitioners, environmental advocates, legal experts and affected communities are needed. In response to this, the UK faculty of public health, EUPHA-law, and the Groningen Centre for health law (in collaboration with lancet countdown, Greenpeace, and other stakeholders) will publish a toolkit for public health practitioners on supporting litigation to protect public health in the context of climate change and other environmental threats to health. The toolkit will answer common questions from public health practitioners: legal systems are as varied as health systems, yet there are principles common to all jurisdictions. In particular, the choice of legal forum is key: which court is best placed to hear a given case? Who can initiate legal proceedings? What is the most suitable legal basis for the claim? It could be under a national constitutional protection of the right to life, a human rights treaty, or environmental or tort law. And, what evidence is required and what evidential standard should be met?

Workshop Aim: The workshop will provide an overview of how the public health community can better support climate change litigation. Sound scientific evidence is as critical to successful litigation as to effective public health policies. Increasingly, public health practitioners are asked to testify in court about the known health impacts of environmental threats. Collecting this evidence requires foresight, meticulous record-keeping, peer support, and the courage to withstand questioning of professional capacity. The workshop will provide an overview of the toolkit content and its proposed uses, building on collaboration with environmental and legal organisations. Opportunities to engage with public health practitioners in the global south will be explored. Participant feedback will be welcomed. The key questions that the workshop will address the workshop will address three key questions: 1) how can the public health competencies be strengthened to understand and support climate change litigation 2) what essential public health functions can contribute to litigation in the context of climate change and other environmental threats to health?, and 3) how can public health professionals work better with lawyers and communities to protect population health in the context of climate change?

Climate, migration and health: questions of ethics and public health

Gözde Ercan¹, Edith Haghnazarian², Colleen Kraft³, Roger Worthington⁴

¹University Of Health Sciences Sancaktepe Training And Research Hospital, Dept. of Child Health and Diseases, Turkey, ²Emergency Department, Los Angeles Children's Hospital, United States, ³University Of Southern California, Keck School of Medicine, United States, ⁴Higher Education Sustainability Initiative, SDG Fellows Groups, 6 St Georges Court, Tunbridge Wells, TN 4 9GX, United Kingdom

Background and Objective: Migration is being increasingly driven by climate change, and the aim of the workshop is to:

consider the ethical implications of migration caused by climate change to help prevent unnecessary harm and suffering; consider learning needs for healthcare professionals treating migrants; consider leadership issues to help ensure sustainable global and public health policy as these trends become more marked. **Methods:** The workshop will begin with a short introduction, followed by small group discussion, ending with a plenary.

Delegates in small groups will consider:

Moral obligations on populations to accommodate migrants forced to relocate because of climate change making it impossible for them to continue living in areas affected by persistent drought, extreme heat and/or frequent/widespread flooding; Continuing professional development needs for healthcare professionals treating migrants from different countries, cultures, and climates; Policy implications for healthcare leaders faced with increasing demand for public health services, for example, in relation to SDGs 3, 4, 5, 6 and 13

Results: Each group will summarise their findings and feedback to the plenary.

Conclusion: During the plenary discussion, facilitators will seek to identify key findings that can be shared and used to prepare for anticipated changes in public health policy and provision in response to climate-related migration.

COP 27: African Perspective

Osahon Enabulele¹, Harsha Somaroo², Armand Nkwescheu³, Lwando Maki⁴, Lwando Maki⁴

¹Coalition of African Medical Associations-Coalition of African Medical Associations Abuja Nigeria" Nigeria, ²Public Health Association of South Africa, Cape Town, South Africa, ³African Epidemiological Association, Abuja, Nigeria, ⁴South African Medical Association South African Medical Association "Pretoria South Africa" South Africa

Background and Rationale

Globally, climate-related disasters killed thousands of lives, affected nearly 100 million people, and a financial cost of US\$310 billion in 2019 alone[1]. South Africa has been witnessing catastrophic manifestations of climate change, including unseasonal snows, veld fires, droughts, and floods.

The United Nations Framework Convention on Climate Change (UNFCCC) is an international treaty that compels its signatories to develop national programs to reduce their emissions of greenhouse gases. The Congress of the Parties (COP) is the supreme decision-making body of the UNFCCC. African countries are signatories to the UNFCCC, the Kyoto Protocol, and the Paris Agreement. The COP held its 27th Conference in Africa at Sharm el-Sheikh Climate Change Conference, held from 6 November until 20 November 2022. Health-related civil society from

around the world attended with PHASA being one from Africa.

The World Health Organisation (WHO); World Federation of Public Health Association (WFPHA) and the Public Health Association South Africa (PHASA) recognise climate change as a threat to individual and population health; acknowledge the environmental footprint of the global healthcare sector; and are acting to reduce waste and prevent pollution to ensure healthcare sustainability. PHASA, therefore, holds membership in the Global Climate Health Alliance Board and has a special interest. PHASA, as one of the leading Public Health organisations in South Africa, sees the professional and moral need to leverage WFPHC to engage its African and Global stakeholders on the African perspectives of addressing the climate crisis to ensure sustainable health systems. PHASA seeks to achieve this by hosting a workshop event at the World Congress of Public Health 2023, in collaboration with current and developing strategic partners.

Objectives: Create a platform to advocate for climate and health related mitigation and adaptation in Africa and globally;

Create a platform to advocate for climate and health related capacity building in Africa and globally;

Create a platform to interrogate the latest data and literature on climate change impacts on health and wellbeing in Africa;

Propose strategies to educate/ raise awareness among health professionals on impact of climate change on health;

To raise the relevance of addressing social determinants of health (SDH), including environmental determinants, to address the climate and health risks, in communities in Africa.

Methodology: A Panel discussion, with moderation.

What does the future of public health need to know about climate-health?

Laurent Chambaud¹, Karl Conyard², Mary Codd³, John Middleton⁴, Tara Chen¹

¹Association of Schools of Public Health in the European Region France, ²Association of Schools of Public Health in the European Region (ASPHER), Ireland, ³UCD School of Public Health Physiotherapy and Sports Science, Ireland, ⁴ASPHER United Kingdom

Synopsis

The climate crisis is a public health emergency. Evidence has highlighted climate change impacts to the social and environmental determinants of health- from clean air, safe drinking water, food security, and even, the built environment. The public health systems have an important role in preventing and reducing these health impacts, requiring further understanding of the intersection of climate change and public health. Climate change brings complex and multi-faceted challenges for public health. Trainees and new graduates are not equipped with the tools to develop effective climate change responses. Academic institutions and public health authorities in the European region have received the call for action to support climate-health training through the EU Health Policy Platform, ASPHER Joint Statement. The joint statement has accelerated leadership buy-in, but the challenge to move forward is exacerbated by the implementation process. ASPHER is currently partnered with various agendas and roadmaps at European and planetary level to move forward with driving climate health conversations which vary from moving forward with deskilling/upskilling the workforce, and reviewing the job market to match workforce needs. This workshop looks to provide the latest research, agendas and policies in the European region from ASPHER and partners, and to share and advocate for climate-health education for the future public health, health workforces and policy makers.

Format

The workshop will be held in a roundtable discussion with three invited panellists who will provide a brief overview of activities from the perspectives of ASPHER (organization), Competencies (education), and Workforce (young professional). Throughout the presentation, there will be intentional opportunities to engage and explore with the audience to understand their background, and their sense of what they see in action and believe is missing in the role of public health in the climate crisis.

Specific Aims/Objectives: • To increase the knowledge of delegates around the latest developments by ASPHER and its partners • To share and reflect the climate-health competencies results with delegates and identify reactions across different roles and countries • To link individuals in the space with the wider network of climate-health advocates in public health • To propose some common actions at European and worldwide level to propel moving forward with climate-health needs

Key Questions

- What is the role of public health systems in climate change?
- What is the role of public health professionals across different career trajectories in the climate

crisis? • How can we support the future public health workforce in education and training?

Following the COVID19 playbook and battling another infodemic: Conspiracy beliefs around human Monkeypox among the Lebanese population

Dalal Youssef¹

¹Ministry of Public Health, Beirut, Lebanon

Introduction: The non-endemic multicountry outbreak of monkeypox (MPX) has emphasized the issue of conspiracy theories that go viral in times of societal crisis. Given the adverse consequences of conspiracy beliefs, this study aimed to assess the extent of endorsement of MPX conspiracy beliefs among the Lebanese population and to identify its associated factors. **Methods:** Using a convenience sampling technique, a web-based cross-sectional was conducted among Lebanese adults. Data was collected using an Arabic self-reported questionnaire. Multivariable logistic regression was performed to identify the factors associated with the MPX conspiracy beliefs scale.

Results: Conspiracy beliefs regarding emerging viruses including MPX were detected among 59.1% of Lebanese adults. Participants endorsed particularly the conspiracy theories linking the virus to a deliberate attempt to reduce the size of the global population (59.6%), gain political control (56.6%) or pharmaceutical companies financial gain (39.3%), and the manmade origin of MPX (47.5%). Remarkably, the majority of surveyed adults exhibited a negative attitude toward the governments preparedness for a potential MPX outbreak. However, a positive attitude was revealed toward the effectiveness of precautionary measures (69.6%). Female participants and those having a good health status were less likely to exhibit a higher level of conspiracy beliefs. Divorced or widowed adults, those having a low economic situation, poor knowledge level, and negative attitude toward the government and precautionary measures were more prone to disclose a higher level of conspiracy beliefs. Notably, participants relying on social media to get information about MPX were also more likely to have a higher level of conspiracy beliefs compared to their counterparts. **Conclusions:** The widespread extent of conspiracy beliefs endorsement regarding MPX among the Lebanese population urged the policymakers to find ways to reduce people's reliance on these theories. Future studies exploring the harmful impacts of conspiracy beliefs on health behaviors are recommended.

Cholera outbreak investigation among children in Nishter Town District Lahore, Pakistan - May- June 2022: a retrospective cohort study

Shamaila Usman¹

¹CDC, Rawalpindi Cantt., Pakistan

In April 2022, National IHR Focal Point of Pakistan reported laboratory confirmed outbreak of Cholera. District Lahore reported highest number of Cholera cases from May – August 2022 in Province Punjab thus been epicenter of Cholera. WHO Global Task Force on Cholera Control focuses on containing Cholera outbreaks. In this regard joint field investigation team was formed of FELTP fellows, Communicable Disease & Epidemic Control Department and WHO to assess magnitude of outbreak, evaluate associated risk factors and recommend Prevention control measures. Retrospective Cohort study was designed on AWD/ suspected Cholera cases enrolled from Children hospital. Cholera suspected case was defined as any child up to 12 years of age presenting with acute watery diarrhea of three or more loose watery (non-bloody) stools and severe dehydration within 24-hour period resident of Nishter town from 15th May -30th June 2022. Pre tested Questionnaire was adopted for Epidemiological Analysis. Environmental drinking Water and stool samples were sent to Public Health Lab for microbiological analysis. Descriptive analysis, attack rates and Risk factors were evaluated by applying logistic regression at CI=95% and p-value<0.05. Out of 288 AWD cases, Vibrio Cholera was isolated in 30 cases (Attack rate 10.4%). The mean age was 3.8 years (Range: 1 -12 years) included 163 (56.5%) male. Data Analysis showed Clustering of Cholera cases in age group 0-2 years(AR= 48%). Among five water sources used by residents, filtration plant water (AR=22%)(RR;4.6 95%CI=2.0-8.2) Municipal water (AR=16.6%)(RR;1.7; 95%CI=0.5-4.9) and Underground water (AR=4%)(RR;0.18; 95%CI=0.08-0.42) had highest water specific attack rates. On Logistic regression AOR 6.77 (CI=2.7-16.7) for filtration plant water was found significantly associated with cholera. Microbiological Examination of Filtration plant water reported E-coli and Coliform growth. **Conclusions:** This was point source outbreak due to Filtration plant mixed with sewage water. Multisectoral

approach and Community awareness on WASH is suggested.

Incidence and determinants of loss to follow-up of human immune virus pre-exposure prophylaxis among key and priority population groups in Addis Ababa health centers, Ethiopia

Addisu Aragaw¹

¹GAMBY medical and buisness collage, Addis Ababa, Ethiopia

Background: 'Loss of follow-up' is a significant public health concern globally. Retention in preventive care among at-risk key and priority population groups is critical for the successful prevention of Human immune virus acquisition. Loss to follow-up of individuals has countless negative impacts on Human immune virus prevention outcomes. There is, however, limited information about the incidence and predictors of loss to follow-up in the study area. Thus, this study aimed to determine the incidence rate and predictors of loss to follow-up among pre-exposure prophylaxis users.

Methods: A retrospective cohort study was undertaken using 240 pre-exposure prophylaxis users between May 2020, and May 26, 2022, at Addis Ababa selected health centers. All eligible clients who fulfilled the inclusion criteria were included in the study.

Results and Discussion: A total of 240 participants with a median age of 32.0 years (interquartile range [IQR]: 27.0 to 40.0) had a median time since initiation of pre-exposure prophylaxis 21.2 months (IQR: 6.5 to 22.1). Almost half 122 (50.8%) were married, Being male is associated with 1.77 times in risk of getting lost than female (ARR=1.77, 95% CI =1.12-2.79).those who had no adherence counseling were associated with 1.86 times in the chance of LTFU as compared to those who had have adherence counseling (ARR=1.863, 95% CI =1.184, 2.930, P-value=0.003). 86 (35.8%) experienced loss to follow-up and the overall incidence rate of loss to follow-up was 7.3 (95% CI: 4.3-12.6) per 100 person-years of observation (PYs). PrEP adherence strategies should developed and designed as a holistic approach, acknowledging the contextual factors of key population groups.

Conclusions: About 35.8% of clients became lost follow-up of pre-exposure prophylaxis users. the overall incidence of 7.3(4.3-12.6) per year of observation. Research preparedness involving key and priority population groups should be strengthened for Human immune virus prevention intervention evaluations in Ethiopia.

Tsetse flies infected with trypanosomes in three active Human african trypanosomiasis foci of the Republic of Congo

Irina Bemba¹, Arsene Lenga², Herman Awono-Ambene³, Christophe Antonio-Nkondjio³

¹Marien Ngouabi University, Democratic Republic of Congo, ²Marien Ngouabi University, Congo, ³Organization for the Coordination of the Fight Against Endemic Diseases in Central Africa (OCEAC), Cameroon

Human African Trypanosomiasis (HAT) is a neglected tropical disease still endemic in the Republic of Congo. Despite the continuous detection of HAT cases in the country, there is still not enough data on trypanosome infections in tsetse flies, trypanosome species and tsetse flies' species distribution in endemic foci. The present study is intended to fill this gap and improve understanding of trypanosome circulation in three active foci in the centre and south of Congo. **Methods:** Pyramid traps were set in various places in villages to collect tsetse flies both during the rainy and dry seasons. Once collected, tsetse flies were identified using morphological keys. DNA extracted from flies was processed by PCR for species identification and for detection of trypanosome presence. A second PCR was ran for different trypanosome species identification.

Results: A total of 1291 tsetse flies were collected. The average apparent density of flies per day was 0.043 in Mpouya, 0.73 in Ngabé and 2.79 in Loudima. Glossina fuscipes quazensis was the predominant tsetse fly collected in Ngabé and Mpouya, while Glossina palpalis palpalis was the only tsetse fly found in Loudima. A total of 224 (17.7%) flies were detected infected by trypanosomes; 100 (7.91%) by Trypanosoma congolense savannah, 22 (1.74%) by Trypanosoma congolense forest, 15 (1.19%) by Trypanosoma vivax, 83 (6.56%) by Trypanosoma brucei (s.l.) and 2 (0.16%) undetermined species. Loudima recorded the highest number of infected tsetse flies. **Conclusions:** The study provided updated information on the dynamics of tsetse fly populations as well as on the transmission of trypanosome species in the different active HAT foci in Congo. These data suggest a high risk of potential transmission of animal trypanosomes in these foci stressing the need for active surveillance in this endemic area.

Malaria remains a public health problem in Cameroon. The prevention of this disease is slowing down by insecticide resistance, mosquito changing behaviour and the fast demographic growth of urban population. To manage those challenges, larval control could be effective. In the frame of a larviciding trial in the city of Yaoundé, a study was conducted in 26 districts from March 2017 to November 2020 to assess its impact on adult anophelinae densities, malaria transmission dynamic and prevalence. A baseline survey was performed during one year then the larviciding was applied in 13 districts while the 13 others served as control. Entomological surveys were carried out once every two months to collect adult mosquitoes using CDC light traps and Human Landing Catches. Mosquitoes were identified up to the species level via PCR then analysed for plasmodium falciparum infectivity via ELISA. Two parasitological surveys were also conducted through malaria testing using blood smears and RDTs while dried blood spots were collected on filter papers to identify Plasmodium species. Slides were stained with Giemsa and examined by microscopy for malaria parasites detection. Indoor and outdoor anophelinae densities recorded with CDC declined by 69.13% and 61.55 % respectively during the larvicide treatment. The same trend was observed with HLC densities regarding the reduction rate of 79.99% and 63.47% recorded. Results also show that the spatio-temporal distribution of anophelinae species in the city was affected by the treatment. In the same way, larviciding reduced indoor and outdoor transmission by 68.97% and 61.77% respectively. The intervention was also associated with a reduction in malaria prevalence. The study highlights the efficacy of larviciding in reducing anophelinae density, malaria transmission and malaria prevalence in the city of Yaoundé Cameroon. This approach could be undertaken to sustain the efficacy of existing tools.

Keywords: larviciding, malaria, transmission, Yaoundé, Cameroon

Association between house characteristics and community practices on anophelines distribution and malaria prevalence during a larviciding program in the city of Yaoundé-Cameroon.

Carmène Ngadjieu¹, Abdou Talipou^{1,2}, Patricia Doumbe-Belisse^{1,3}, Landre Djamouko-Djonkam^{4,2}, Parfait Awono-Ambene⁵, Sevilor Kekeunou¹, Charles Wondji⁶, Christophe Antonio-Nkondjio²

¹Faculty of Sciences, University of Yaoundé I, Yaoundé, Cameroon, ²Laboratoire de Recherche sur le Paludisme, Organisation de Coordination pour la Lutte Contre les Endémies en Afrique Centrale (OCEAC), Yaoundé, Cameroon, ³Laboratoire de Recherche sur le Paludisme, Organisation de Coordination pour la Lutte Contre les Endémies en Afrique Centrale (OCEAC), Yaoundé, Cameroon, ⁴Vector Borne Diseases Laboratory of the Biology and Applied Ecology Research Unit (VBID-URBEA), Department of Animal Biology, Faculty of Science, University of Dschang, Cameroon, ⁵Laboratoire de Recherche sur le Paludisme, Organisation de Coordination pour la Lutte Contre les Endémies en Afrique Centrale (OCEAC), Yaoundé, Cameroon, ⁶Vector Group Liverpool School of Tropical medicine Pembroke Place, Liverpool, United Kingdom

The most efficient malaria vectors bite and rest inside houses, hence houses play a determinant role in malaria transmission. During the implementation of additional vector control tools such as larviciding, individual disease risk perception could be affected. We carried out this study to evaluate the influence of house structures, community knowledge and practices on anophelines diversity and malaria prevalence, before and during a larviciding program. The study was

conducted before and during larviciding intervention in 26 districts. Indoor CDC light traps were used to collect mosquitoes. Questionnaires were administered to collect data on house characteristics and to evaluate the impact of larviciding on population knowledge and behaviour. After morphological identification, anophelines were tested by ELISA to detect infection to Plasmodium parasites. RDT was used to test the blood samples of participants. Binary analyses were used to assess the correlation between different variables. The majority of houses were made with cement walls. The most abundant anophelines was An. coluzzii, followed by An. gambiae s.s, with the highest densities in traditional houses before the treatment in control sites, whereas, they were most abundant in modern houses in treated sites. Opened eaves and absence of ceiling exposed people to anophelines bites. Possession of LLINs before the treatment in control sites exposed people to anopheline bites while they were protected in treated sites. Infection to Plasmodium and malaria prevalence were highest in modern houses found in control sites; while in treated sites, infection to Plasmodium was highest in modern houses, but malaria prevalence was the same in both house types. People who lived in treated sites knew more about malaria prevalence and mosquito breeding sites, and the latter used fewer LLINs. Well-built houses protect people against anophelines species. The implementation of larvicide control improved the knowledge of people and decrease their personal protection against mosquito bites.

Assessing dengue and chikungunya infections among febrile patients visiting four healthcare centres in Yaoundé and Dizangué, Cameroon

Stella Nana-Ndjangwo¹, Borel Djiappi-Tchamen^{2,3}, Ruth Mony⁴, Maurice Demanou⁵, Joyce Keumezeu-Tsafack^{6,3}, Roland Bamou⁷, Parfait Awono-Ambene⁸, Charles Bilong⁴, Christophe Antonio-Nkondjio⁸

¹University of Yaoundé I, Cameroon, ²University of Dschang, Dschang, Cameroon, ³Organisation de Coordination pour la lutte contre les Endémies en Afrique Centrale (OCEAC), Cameroon, ⁴University of Yaoundé I, Yaoundé, Cameroon, ⁵World Health Organization, IST West Africa, Ouagadougou, Burkina Faso, ⁶University of Douala, Cameroon, ⁷OCEAC (Organisation de Coordination pour la lutte contre les Endémies en Afrique Centrale), University of Dschang, Dschang, Cameroon, ⁸OCEAC (Organisation de Coordination pour la lutte contre les Endémies en Afrique Centrale), Yaoundé, Cameroon

Dengue and chikungunya are widely distributed in Cameroon but there is still not enough information on their prevalence in different epidemiological settings. This study was undertaken to assess dengue and chikungunya prevalence in both urban and rural settings in Cameroon using 3 diagnostic tools. From December 2019 to September 2021, willing febrile (temperature >38°C) outpatients visiting 4 healthcare facilities in the cities of Yaoundé and Dizangué were screened for dengue and chikungunya. Clinical symptoms were recorded and blood samples collected in EDTA tubes were centrifuged to obtain plasma, then analysed using rtRT-PCR, RDTs and ELISA. Odds ratios were used to determine the level of association between socio-demographic factors, clinical features and the infection status. Kappa statistic permitted to assess the level of agreement between RDTs and ELISA. Overall, 301 patients were recruited: 198 in Yaoundé and 103 in Dizangué. The prevalence varied according diagnostic tool. For dengue, 110 patients were positive to rtRT-PCR: 90 (45.45%) in Yaoundé and 20 (19.42%) in Dizangué. The prevalence of dengue IgM using ELISA varied from 22.3% in Dizangué to 30.8% in Yaoundé. Dengue positivity rate using RDTs was 7.6% in Yaoundé and 3.9% in Dizangué. For chikungunya, one (0.5 %) patient (Yaoundé) was tested positive to rtRT-PCR. The prevalence of chikungunya IgM with ELISA varied from 18.4% in Dizangué to 21.7% in Yaoundé, while using RDTs, it was 4.5% in Yaoundé and 12.6% in Dizangué. RDTs for either chikungunya or dengue displayed very poor sensitivity. Abdominal and retro-orbital pains were significantly associated to acute dengue infection. All the four dengue serotypes were recorded with a predominance of DENV-3 (35.45%) and DENV-4 (25.45%). This study further confirms endemicity of both dengue and chikungunya in Yaoundé and Dizangué. These data stress the need for active surveillance of cases to prevent outbreaks occurrence across the country.

Tuberculosis-related knowledge, practices, perceived stigma and discrimination, and adherence to anti-tuberculosis medication among patients with tuberculosis

Rana Hamawi¹

¹GHD Eastern Mediterranean Public Health Network (EMPHNET), Jordan

Background: Tuberculosis is ranked among the top 10 causes of death worldwide and is the leading cause of death from a single infectious agent. Tuberculosis knowledge, practices, adherence to treatment, perceived stigma, perceived family and health workers support among patients with tuberculosis are key factors in management of the disease. This study aimed to assess tuberculosis related knowledge and practices, perceived stigma, discrimination and their associated factors, adherence to medication and its associated factors, reasons for diagnosis/treatment delay, perceived family and health workers support, perceived level of satisfaction with healthcare services and impact of COVID-19 among patients with TB in Jordan.

Methods: A cross-sectional study was conducted among patients who were under treatment for Tuberculosis in Jordan. A structured questionnaire was developed, and pilot tested among 10 patients with tuberculosis. Categorical variables were described using percentages and quantitative variables were described using means and standard deviations. General linear procedure and binary logistic regression were used to determine association with different variables.

Results: The majority of patients with tuberculosis had low to moderate overall tuberculosis-related knowledge score. The duration between the onset of tuberculosis symptom(s) and diagnosis had a mean of 43.2 days and the duration between diagnosis and treatment had a mean of 6.4 days. The majority of patients with tuberculosis thought that there was a delay in diagnosis and/or treatment of tuberculosis.

Conclusions: Efforts should be made to increase public awareness and knowledge about tuberculosis and to educate them about the importance of seeking early care. A patient centric approach, where motivational counseling and patient support groups should be adopted.

The first national prevalence survey of soil transmitted Helminths in Pakistan

Waleed Rabbani¹

¹Interactive Research and Development, Lahore, Pakistan

Objective: WHO estimates, 21.7 million School Age Children in Pakistan are infected with STH, along with 9.3 million preschool-age children. However, prior to implementing the large-scale deworming program, it was necessary to determine the geographical distribution of STH in the country. The Objective of the survey was to report the prevalence and intensity of STH across Pakistan and provide information to the government for evidence-based interventions.

Methods: WHO's sentinel site approach was used to estimate the baseline prevalence of STH infections. Schools were considered sentinel sites whereby one school was selected for every 300,000 children aged 5-10 years in each of the nine ecological zones of Pakistan. Mobile lab teams with technical and non-technical members were deployed in four provinces (Punjab, Sindh, Baluchistan, and Khyber Pakhtunkhwa (KPK)) as well as the territory of Azad Jammu and Kashmir (AJK). A total of 77 schools across the country were approached, and 5188 parents consented to their child's stool being analyzed for STH using the Kato-Katz Methodology.

Results: The weighted prevalence of STH in the different ecological zones ranged from 0% to 37.5%, there are regions where the prevalence is significantly higher. Rawalpindi and Gujrat have a prevalence of 56% and 36%, respectively, representing the highest prevalence in the Northern Regions of Punjab. STH is endemic across Northern regions of KPK, with the highest prevalence around the district of Swat (37%). Much of the Southern Region of Pakistan has low levels of infection, with the notable exception of the Karachi area where prevalence reaches 20%. The survey also revealed that hygiene and sanitation infrastructure and basic hygiene practices at schools and households across all areas were poor.

Conclusions: There are regions with a sufficiently high prevalence of STH that indicate that mass deworming programs should be conducted that subsequently renders a multi-dimensional impact on health, education, and livelihood.

Adherence and factors associated with Cotrimoxazole preventive therapy among adult human Immunodeficiency Virus (HIV) Patients attending antiretroviral clinics in Jigjiga Hospitals

Shyamkumar Sriram¹, Seada Kasim²

¹Ohio University, Ohio, United States, ²Jigjiga University, Ethiopia

Background: Co-trimoxazole, a fixed-dose combination of two antimicrobial drugs offers a synergistic effect with a broad spectrum of antimicrobial action. Adherence to cotrimoxazole preventive therapy has been found to reduce

the incidence of opportunistic infections and other AIDS-related illnesses. Cotrimoxazole preventive therapy is self-administered, and therefore, adherence cannot be insured, and the adherence has been low and opportunistic infections continue to be the major cause of mortality and morbidity in HIV, accounting for 47% of AIDS-related deaths. This study aimed to assess adherence and factors associated with cotrimoxazole preventive therapy (CPT) among adult human immunodeficiency virus (HIV) patients attending antiretroviral clinics in Jijiga hospitals.

Methods: Institutional-based-cross-sectional study was conducted from November to December, 2021 among 422 randomly selected adult HIV-positive patients attending Jijiga hospital. The collected data was entered into EPI-data version 3.1 and exported to SPSS version 24 for analysis. Binary and multivariable logistic regressions were used to identify factors associated with CPT adherence. **Results:** 417 patients with HIV participated in the study with an overall adherence of CPT of 76.3% with 95% confidence interval (CI): 72.4%-81.3%; level of education can read and write (AOR= 1.50, 95% CI: 1.39 -2.73), taking substance (AOR= 1.88, 95% CI: 1.22-2.93), distance of the health facility greater than 5km (AOR= 1.79, 95% CI: 1.07-2.98), residence being rural (AOR =1.90, 95% CI: 1.14-3.17) not receiving counseling at refill (AOR= 1.33, 95% CI: 1.13-2.80), duration of ART less than 6 years and not disclosing HIV status to other family members (AOR =5.40, 95% CI: 3.42-8.14, and 3.30, 95% CI: 2.12-5.41 respectively) were significantly associated with magnitude of CPT.

Conclusions: To improve the adherence, continuous education and counselling, giving group service support for clients and patients having trends to disclose HIV status to other members of the family are some of the possible solutions.

Measles seroprevalence national survey among a sample of the Tunisian population: is there an explanation for the 2019 measles epidemic in a mostly vaccinated population?

Emna Mziou¹, Mouna Safer², Aicha Hchaichi³, Fatma Youssef³, Hejer Letaief³, Sonia Dhauadi², Leila Bouabid², Soudes Derouiche², Rym Mhadhbi², Souha Bougatef², Olfa Bahri⁴, Nissaf Alaya⁵

¹National Observatory of New and Emerging Diseases, Sfax, Tunisia,

²National Observatory of New and Emerging Disease, Tunis, Tunisia,

³National Observatory of New and Emerging Diseases, Béja, Tunisia,

⁵Department of Microbiology and Biochemistry, Hopital Aziza Othmana,

Tunis, Tunisia, ⁶Observatoire National des Maladies Nouvelles et

Émergeantes, Tunis, Tunisia

In Tunisia, the measles vaccine is included in the national-immunization-programme. An outbreak of measles occurred with 3896 notified cases and 39 deaths in 2019. We conducted this study to estimate measles IgG-antibodies seroprevalence before the occurrence of 2019-outbreak. We conducted a national seroprevalence survey of measles immunity using blood samples serocheque collected during the 2014-2015 National Viral Hepatitis cross-sectional survey. Written informed consent for using the sera for further analysis was obtained from participants (parents for minors). A subsample of 3500 individuals was included based on expected seroprevalence of 85%, a precision of 0.2% and 95%CI. ELISA was used to detect IgG antibodies against measles. Participants with serum positive for measles antibody were considered protected or immune to measles disease. From 3454 serum samples tested, 3279 were positive for measles IgG antibodies, representing a seroprevalence of 94.9% (95%CI: 94.3%-95.6%). Seroprevalence was significantly lower in rural area (p<0.001). The prevalence of measles IgG antibodies was different by age (p<0.001). The seroprevalence among children aged 0-5 years was 94.7%. It was 96% for both 5-10- and 10-15-year-old populations. However, it declined significantly among 20-30 years population, 1982-1997 birth cohort, with a seroprevalence of 83.2% (95%CI: 79.7%-86.1%). Among 40-50, 50-60 and >60-year-old populations, seroprevalences were to 98.1%, 99.2%, and 98.6% respectively. In this context, during 2021, the Tunisian government, provided and recommended getting a booster dose targeting adults born between 1982-1997 (20-30 years), and advancing the first dose for children from 12 to 9 months, in order to ensure a sufficient immunization rate. This study, a pre-epidemic measles seroprevalence survey, showed that seroprevalence among vaccinated population aged 20-30 years in Tunisia was low. To prevent future outbreaks, a nationwide-vaccination-campaign was implemented in 2021, aiming to boost immunity against measles. It was delayed for 2022, as a consequence of the COVID-19 pandemic.

Short hospital stays for malaria cases despite gaps in

management: case scenario for high and low malaria endemic counties of Kenya, 2021

Nassoro Mwanyalu¹, Freshia Waithaka², Dorcas Mutiso³, Maurice Owiny³

¹Field Epidemiology and Laboratory Training Program, Zoonotic Disease Unit, Ministry of Health, Nairobi, Kenya, ²Field Epidemiology and Laboratory Training Program, Ministry of Health, Kenya, ³Field Epidemiology and Laboratory Training Program-Ministry of Health, Kenya

Introduction: Kenya Malaria Strategy(KMS) 2019–2023 targets to reduce malaria incidences and deaths by at least 75% by 2023. In 2020, there was a decline in facilities reporting inpatient malaria data by 18%, reducing the number of malaria admissions in the country. Therefore, we aimed to assess inpatient Malaria cases, case management and Data Quality Audits in low and high malaria endemic counties of Kenya.

Methods: We used a mixed-method approach in Makueni, Taita-Taveta and Lamu counties. We retrieved reports from Kenya Health Information System(KHIS), reviewed inpatient registers and medical records for malaria data from admitting facilities. All malaria records for clients attended, 2020-2022 were eligible. We administered questionnaires to healthcare workers in the visited facilities to assess malaria case management. Descriptive statistics were performed.

Results: Of the 23 inpatient facilities visited, only 52% reported into the KHIS platform; Makueni at 45%(5/11) and Lamu at 36%(4/11) contributed the highest number of facilities not reporting. A total of 131 malaria records were abstracted, ages ranging from three months to 72 years(median 22 years), with a Case fatality rate of 2.3%. Makueni county being a low-risk county, had more cases than Lamu county at 33%(44/131). On diagnosis, 46%(60/131) were uncomplicated, while 1.53% were clinical malaria admissions. Those treated with Artemether-lumefantrine(AL) and Artesunate drugs were 61%(80/131) and had the shortest hospital stay, 1–7 days. Only 51%(36/70) of healthcare workers were trained in malaria case management, and 44%(16/36) were clinicians. On International Classification of Diseases 10/11, 59%(13/22) of Health records officers were trained, and 36%(10/28) of laboratory officers were not conducting malaria species quantification.

Conclusions: Patients treated with both Artemether-lumefantrine and Artesunate drugs were below the 80% KMS target and had shorter hospital stay. There were gaps in malaria diagnosis and management of cases.

The effectiveness of the prevention and control methodsapplied towards the elimination of malaria in Botswana

Collen Saudu¹

¹Young Leaders Organization, Johns Hopkins University, United States

Background: In 2008 the Ministry of Health (MOH) in Botswana was inspired by an overall decline of malaria prevalence within the population from 4.2% in 2000 to less than 1% in 2008. These Results motivated the government of Botswana to embark on complete elimination of malaria by 2015. Heavy rainfalls in 2017 led to an epidemic which caused a huge setback to this elimination target, due to the malaria cases reported in the South-East District, a region not classified as endemic in Botswana. This study examines the progress, effectiveness, and challenges of prevention and control methodsfor a successful elimination of malaria in Botswana.

Materials and Methods: Retrospective data about cases of malaria in Botswana covering endemic districts, and data about Indoor Residual Spray (IRS), Long lasting Insecticides Nets (LLINs) and larviciding from 2000 to 2018 were obtained from the Botswana MOH. Rainfall data from the Department of Metrological Services were also obtained. Intervention datasets were compared against rainfall amount and number of cases to establish their relationship.

Results: There was a direct proportion between percentage of malaria incidence and percentage of mean annual rainfall. Intensifying interventions in Botswana had no effect on number of cases based on this study. IRS coverage and intensity increased over years to 80%, yet one heavy rainfall season Resulted in increased cases of malaria in Botswana.

Conclusions: Improved forecasting can be used to predict malaria in Botswana, indicating malaria in Botswana is heavily dependent on the climate . IRS, LLINs and larviciding should be carried out at the right time, not after mosquito bites and consistently without failure, to eliminate malaria. The steep decline of cases of malaria from 2000 to 2013 was due to the dry weather, not control methodsapplied.

The increasing problem of Tuberculosis in Nepal

Prabin Shrestha¹

¹Young Professional Development Society Nepal, Nepal

Background and Objective: Tuberculosis (TB) is a major public health problem in Nepal. It is a major cause of ill-health, one of top ten causes of deaths and leading cause of death from single infectious agent. Government of Nepal has put TB as a priority program and is committed to eliminate TB. The aim of the study was to describe the problem of TB epidemic in Nepal. Methods: Different literatures, reports, policy documents and guidelines were reviewed and the Results were presented through descriptive analysis.

Results: In 2018/19, Nepal conducted the first National TB Prevalence survey, which showed higher prevalence, incidence and mortality of TB than the previous estimations. The TB prevalence was estimated to be 416/100000 with around 117000 people with TB disease in the country living. Similarly, the incidence was found to be 245/100000 with an estimated of 69000 cases. The mortality was also found to be 3.1 times higher than the previous estimates. In the year 2020/21, National TB Programme (NTP) registered 28,677 (38% females and 62% males) cases with nearly 58% missing cases than the projected cases showing higher incidence notification gap. The missing cases were higher among elderly due to challenges in access to health care services. Of the registered cases, the proportion of childhood TB was found to be 6.6% which was low suggesting existence of high TB transmission and requiring early diagnosis and treatment of childhood TB. The case notification rate (CNR) was 95 per 100000 population and 9 districts were considered to be high TB burden districts based on the CNR. **Conclusions:** There exists a huge gap between the estimated and notified cases. NTP must work to reduce the gap and identify the missing cases through accountable, equitable, quality, universally accessible and patient centered care and services.

Knowledge of Monkeypox among medical students in the Eastern Mediterranean Region

Assem Gebreal¹, Samar ElHafeez², Shaimaa Abdelmoneim³, Ramy Ghazy⁴

¹Faculty of Medicine, Alexandria University, Egypt, ²Epidemiology Department, High Institute of Public Health, Alexandria University Egypt, Egypt, ³Alexandria Clinical Research Administration, Alexandria University, Egypt, ⁴Tropical Health Department, High Institute of Public Health, Alexandria University, Egypt

Background and Objective: Human monkeypox epidemic represents a public health emergency. In epidemics, medical students act as alert and reliable public information sources. This study aimed to assess knowledge of Monkeypox among medical students recruited from the Eastern Mediterranean Region

Methods: A cross-sectional study was performed between August-October, 2022. Data was collected through an online predesigned questionnaire that was distributed via social media. The questionnaire consists of two sections; the first is on the sociodemographic characteristics (gender, age, educational year), and the second section included 30 items to assess the knowledge on HMPX (five items on the source and nature of HMPX, 7 items on the mode of transmission of HMPX, 6 items on the clinical manifestation, 8 items on the prevention and control, and 4 items on treatment modalities). The level of knowledge was classified into high (80-100%), moderate (60-80%), and low (less than 60%). For analysis, descriptive statistics were performed.

Results: A total of 1,740 medical students participated in the study. The mean age of the participants was 21 years, 63% were females, and 47% of them were in the fifth and fourth-year. Only 10% received a training program on human monkeypox. The findings from this study showed that the majority of participants 848 (48.73%) had a moderate level of knowledge regarding HMPX, 274 (15.747%) had poor knowledge, and 618 (35.49%) had high knowledge. Almost one-third (32%) had knowledge of the availability of the licensed monkeypox vaccine. There was no significant association between knowledge and education year, country of residence, or area of residence (urban/rural) ($p=0.23$), ($p=0.92$), ($p=0.07$) respectively.

Conclusions: The study emphasized that knowledge towards human monkeypox introduced to currently enrolled undergraduate medical students in the Eastern Mediterranean Region is inadequate and should be increased to enhance the prevention and control of monkeypox.

Case of yellow fever in the Manankoro area, Bougouni health district, Sikasso region, December 2019

Soungalo Diakite¹

¹Responsible for Epidemiological Surveillance of Infectious Diseases,

Ministry of Health and Social Development of Mali, Mali

Introduction: Following the confirmation of two (2) cases in the health district of Bougouni on 03/12/2019. We conducted an investigation whose objective was to describe the cases of yellow fever in the Manankoro health area in time, place and people and to put in place control and prevention measures against the epidemic. **Methodology:** We conducted a cross-sectional descriptive study in December 2019, a case of yellow fever was any person who stayed in Manankoro or surrounding village between October 20 to December 05, 2019 and who presented during this period the following signs: Fever or notion of fever in the previous days and jaundice in the 2 weeks following the onset of the signs. We conducted a search for other unreported cases based on data collected using a questionnaire. The data was analyzed in time, place and person. **Results:** Case confirmed by the laboratory, this is a 25-year-old adult, farmer, male gender, residence Kémingouara / Republic of Côte d'Ivoire, came on November 06, 2019 for consultation at the Lafia cabinet in Manankoro in a table of coma and referred to the CSRéf of Bougouni for better care where he died 11 hours after his blood sample on 08/11/2019. **Conclusions:** The investigation made it possible to identify 12 additional cases among which 3 cases of death, the age group of 30 to 34 years was the most represented, that is to say 33%. The male sex was predominant with 10 cases. Fever, jaundice and vomiting were the most frequent symptoms. The *Aedes* species responsible for yellow fever was not found during this investigation.

Role of genetic variability in Toll-Like receptors (TLR2, TLR4 and TLR9) in HIV-1 disease progression

Gaurav Kaushik¹, Richa Vashishtha²

¹Department of Allied Health Sciences, Sharda University, India, ²All India Institute of Medical Sciences (AIIMS) New Delhi, Rajnagar, India

Background: It has been demonstrated that TLR2, TLR4 and TLR9 which were initially known for recognizing bacterial product are involved in detection of viral components. It was planned to undertake a prospective longitudinal study among ethnically homogenous ART and ATT naïve HIV-positive patients representing the north Indian population. The aim of the study was to investigate the influence of TLR2, TLR4 and TLR9 polymorphism in HIV disease progression. **Methods:** Present study was designed to investigate genetic polymorphism in TLRs (TLR2, TLR4 and TLR9) among HIV-infected patients with and without TB co-infection. The study population consisted of two groups (i) HIV-positive patients without TB infection and disease (n=223, HIV+ patients); (ii) HIV-positive patients with latent tuberculosis infection (n=150, HIV+LTBI patients). These subjects were of either gender between 18-60 year of age and treatment naïve for both TB and HIV. HIV+ and HIV+ LTBI patients were longitudinally followed-up for the period of two years to study HIV disease progression.

Results: On comparing TLR2 and TLR4 allelic and genotypic frequencies between 306 HIV+ patients (no TB/AIDS) and 47 HIV+ patients progressed to active TB/AIDS, no significant difference was observed between two groups. The frequency of 'A' allele in TLR9 was found to be significantly increased in 47 HIV+ patients who progressed to active TB/AIDS (61.7%) as compared to 42.16% in 306 HIV+ patients (no TB/AIDS), (p<0.001). Also, a significant increased frequency of 'AA' genotype in TLR9 was observed in 47 HIV+ patients progressed to active TB/AIDS (55.32%) as compared to 20.26% in HIV+ patients (no TB/AIDS). **Conclusions:** Findings of the present study revealed that genetic variability in TLR9 may influence the HIV disease progression. The AA genotype in TLR9 may be associated with progression to TB/AIDS during 2-year time period in HIV+ patients.

Demographic and housing factors in Lassa fever transmission in a high disease burden State in Nigeria

Alphonsus Aigbiremolén¹, Faith Ireye², David Anderson³, Stephanie Hsieh³, JaMuir Robinson³, Danny Asogun^{4,5}

¹Department of Community Medicine, Irrua Specialist Teaching Hospital (ISTH), Irrua, Edo State, Nigeria, ²World Health Organization, Asaba, Nigeria, ³Walden University, Baltimore, United States, ⁴Department of Community Medicine, ISTH, Irrua, Edo State, Nigeria, ⁵Irrua Specialist Teaching Hospital (ISTH), Irrua, Edo State, Nigeria

Background and Objective: Lassa fever is endemic in Nigeria and there are yearly outbreaks in many areas including Edo State with associated severe morbidity and high mortality rates. Empirical evidence on the contribution or otherwise of socio-demographic characteristics to transmission of the infection is sparse. This study was designed to determine demographic and housing factors related to Lassa

fever transmission in Edo State, Nigeria. **Methods:** This was a cross-sectional study in which a sample of 336 adults was drawn from 6 Local Government Areas (LGAs) in the state using multi-stage sampling technique. A questionnaire was used to obtain information from respondents. Analysis of data was done using SPSS version 25 and relationship between demographic and housing characteristics and transmission of Lassa fever were tested with Chi square and multi-nomial logistic regression.

Results: Majority of respondents (76.5%) lived in rural areas. More than two-thirds (69.9%) resided in brick houses, 54.8% reported presence of rodent entry points in their houses, and more than one-third were observed to have bushy or littered house surroundings. Urban residence, ethnicity, and poor housing were significantly associated with high Lassa fever transmission (X²= 54.490, p<0.001; X²= 66.648, p<0.001; X²= 25.435, p<0.001 respectively). Rural residence increased the odds of low transmission by 6.991 times (B= 1.945, 95% CI: 3.580-13.651). **Conclusions:** There is a significant relationship between some demographic and housing characteristics with transmission of Lassa fever. Effective and sustainable control strategies for the deadly disease require strong consideration of these factors. **Keywords:** Lassa fever, demographic factors, housing, Edo State

The case for collecting, analysing, and utilizing sex-disaggregated data and gendered data to inform outbreak responses, a systematic review of the literature 2012-2022

Emelie Phillips¹, McKenzie Gales², Shirin Heidari³, Leah Pao², Marie-Amélie Degail⁴, Christine Dubrey², Clara Ribas⁴, Marie Meudec⁵, M. Siddiqui⁶, Simone Carter⁷

¹Epicentre, Türkiye, ²Centers for Disease Control, United States, ³GENDRO, Switzerland, ⁴World Health Organisation, Switzerland, ⁵Institute of Tropical Medicine Antwerp, Belgium, ⁶UNICEF, United Kingdom, ⁷UNICEF, Democratic Republic of Congo

Introduction: Understanding sex-related differences and gendered roles in outbreak dynamics is critical to deliver an effective response. We examined the extent to which sex-disaggregated data and gendered data for outbreak analytics and responses are collected, analyzed, and utilized in low-and middle-income countries (LMIC).

Methods: A systematic literature review was conducted. Five databases were searched for peer-reviewed literature examining sex- and gender-specific outcomes for communicable disease outbreaks, published in English between January 1, 2012, and April 12, 2022. Results were independently screened, and all articles meeting the inclusion criteria were included in the review.

Findings: A total of 71 out of 15,601 screened articles were included in the analysis. The literature describes sex- and gender-related differences in outbreak susceptibility, risk of exposure, symptoms, severity of illness, healthcare-seeking behavior, and access to treatment and support services. Findings varied by disease, setting, and population. Gaps in the analysis and use of sex-disaggregated data and gendered data in outbreak response were identified. The analysis showed that identified sex and gender-related differences were not systematically utilized to address sex and gender-related barriers to health, implement sex and gender-specific prevention messaging, and adapt disease detection and treatment across all aspects of the outbreak response.

Conclusions: Despite existing recommendations and minimum requirements, collection, analysis, and use of sex-disaggregated data and gendered data, including operational analytics, are seldom included in outbreak response. While sex data is often collected during outbreaks in LMIC, few publications disaggregated outcomes by sex or discussed gendered roles in outbreak dynamics, and even fewer examined the implications of the observed differential outcomes. Mounting evidence calls for an approach to outbreak prevention, detection, response, and recovery that includes sex and gender specificities. Context-specific guidance for the systematic collection, analysis, and utilization of sex-disaggregated data and gender data is urgently needed.

Screening campaign for the elimination of the Hepatitis C virus in the generic risk population born between 1969 and 1989 in an Italian Local Health Authority - preliminary data

Doriana Vallone¹, Samantha Rollo¹, Vincenzo Allegretti¹, Catia Sias², Luca Casertano³, Giuseppe Luzio¹, Giancarlo Pizzutelli¹

¹Department of Prevention, ASL Frosinone, Frosinone, Italy, ²Department of Clinical Pathology, ASL Frosinone, Frosinone, Italy, ³Medical Management, ASL Frosinone, Frosinone, Italy

Background and Objective: Chronic infection caused by the hepatitis C virus (HCV) represent the main causes of morbidity and mortality related to liver disease. An estimated 3.9 million individuals are chronically infected with HCV in EU/EEA countries. In Lazio it's estimated about 53000 patients with chronic active HCV infection who have not yet been treated with antiviral therapy. The purpose of this free screening, promoted by the Ministry of Health and launched also in the Lazio Region, is to identify, among the subjects enrolled in our Local Health Authority of Frosinone (ASL), the positivity to HCV antibodies (HCVAb) and reflex testing for HCV RNA by serological testing, for start them the assessment to free specific treatment.

Methods: In our Asl, this screening started on 4 Oct 22 and will end on 31 Dec 23. The target population is represented by subjects born between 1969 to 1989. Therefore, circa 140000 subjects in the Province of Frosinone are eligible. The team of the HCV screening coordination provide through an active phone-call and by sending an ordinary mail to invite the eligible subjects to participate at the screening, fixing an appointment for the blood test in one of the centers of our ASL, based on the residence; eligible subjects can still self-booking on "Salute Lazio". **Results:** The preliminary data as of 2 Dec '22, shows that out of n. 570 exams booked in our ASL: n. 384 subjects tested negative for HCV AB; only n.1 subjects tested positive for HCV Ab and negative for HCV RNA. No positive reflex testing for HCV RNA was currently found.

Conclusions: Without an effective hepatitis C vaccine, this screening can detect undiagnosed HCV infections and improve early diagnosis for health care coverage policies and clinical decision making; as well as interrupting the circulation of the virus, preventing new infections.

DOI: 10.18332/popmed/165402

Private sector care-seeking pathways and delays in TB care in India, Indonesia and Nigeria in times of COVID-19

Charity Oga-Omenka¹, Nathaly Vasquez², Angelina Sassi², Rishav Das³, Madhukar Pai², Lavanya Huria⁴, Bony Lestari⁵

¹University of Waterloo, Canada, ²McGill University, Canada, ³McGill University, Canada, ⁴McGill International TB Centre, Canada, ⁵Department of Epidemiology and Biostatistics, Universitas Padjadjaran, Indonesia

India, Indonesia, and Nigeria have the 1st, 3rd, and 6th highest burden of TB globally. Combined, they accounted for 44% of new cases and 50% of deaths from TB globally in 2021. In these countries, a majority (71% on average) of initial TB care-seeking are with private providers, yet private providers accounted for only 15-31% of TB notifications. The WHO reported that there are 1.8M (or 43% of global total) people with TB that are were not diagnosed in these countries. Reports also show that COVID-19 pandemic has reversed years of progress in the TB response due to control measures and overwhelmed healthcare systems. Our study in these 3 countries show how care-seeking pathways for TB care has changed in 2021, and what implications these changes have for health system recovery post-pandemic. We used cross-sectional surveys with 529 patients in India (n=200), Indonesia (n=149) and Nigeria (n=180) to find onset of symptoms, care-seeking pathway, TB diagnosis and treatment initiation, healthcare use during COVID-19, and the impact of COVID-19 on their care. The results showed significant increases in care-seeking delays, and in numbers of encounters with public and private sector providers. Our study highlights the need to strengthen public-private partnerships, equip the private sector with more access to TB testing tools, implement effective bidirectional screenings for TB and COVID and increase training for private providers on TB detection.

Candida auris: a bibliometric analysis of an emerging global health threat

Paolo Ragusa¹, Simone Pizzini¹, Alessandro Prinzivalli¹, Giulia Libero¹, Giuseppina Moro², Valerio Brescia³, Giacomo Scaioli¹, Davide Minniti⁴, Roberta Siliquini¹, Fabrizio Bert⁵

¹Department of Public Health Sciences, University of Turin, Italy,

²Department of Sciences of Public Health and Pediatrics, University of Turin, Italy, ³Department of Management, University of Turin, Italy, ⁴Health Local Unit ASL TO3, Turin, Italy, ⁵University of Turin, Department of Public Health Sciences, Italy

Background and Objective: Candida auris (CA) is an emerging fungus identified in 2009 that, given its worldwide spread and unique characteristics, has been classified as an urgent global health threat: it resists to common antifungal drugs and decontamination procedures; identification requires specific tools; transmissibility and mortality are high in healthcare settings, especially for

patients in intensive care units. Infection and colonization can be long-lasting, leading to problems in isolation procedures and the risk of outbreaks. This study aims to evaluate publication and citation related metrics, identify major Keywords and topics, and assess geographic distribution of published articles.

Methods: A list of all publications containing "Candida Auris" in all fields was extracted from Web Of Science on date 2022/11/18. Bibliometric analysis was conducted using the bibliometrix and biblioshiny packages on RStudio.

Results: Total publications (TP) were 1234 with an annual growth rate of 51.58%. Only 12.7% of 4859 contributing authors published ≥ 3 articles about CA. Total citations were 26901, with an average of 21.8 citations per paper. The core sources are 9 out of 317, according to Bradfords law. In only 42 countries where CA was identified, articles on the topic were published (89%). The origin of TP is heterogeneous: 31% Europe, 29% North-America, 25% Asia, 8% South-America, 4% Africa, 3% Oceania. Trending topics about CA include epidemiology, identification and resistance.

Conclusions: Our analysis shows a growing interest in scientific literature on the topic of CA, led by Europe. In some countries where CA has been identified, no papers have been published. Despite the multidrug-resistance of CA, the topic of therapy is not much debated. Our findings highlight the need to increase focus on CA in order to promote health systems' preparedness and to properly address the spread of this worrisome pathogen.

Epidemiological and clinical differences of cases of MPOX at the Chilean outbreak

Alejandra Acevedo¹, Marcela Valdebenito²

¹Magíster en Epidemiología, Universidad de los Andes, Santiago, Chile,

²Departamento de Epidemiología y Estudios en Salud, Universidad de Los Andes, Clínica Universidad de los Andes, Chile

Background: In the present MPOX outbreak, differences related to clinical and epidemiological features have been observed with respect to historical evidence. In Chile, the first case was reported in June and until now, there are more than 1400 cases. **Objective:** To identify differences between confirmed and discarded cases of MPOX during 2022 Chilean outbreak. **Methods:** This is a retrospective case-control study from the Institute of Public Health database from all suspected cases between June 1st and September 30th of 2022. Patient samples were processed by real-time PCR at the same Institute. RStudio and Microsoft Excel were used for statistical analysis. Means, frequencies and percentages were calculated. Fisher's test was used to compare groups.

Results: We collected 1456 suspected cases. 87% were men between 30-39 years. Positivity increased from 20% at the start to 73% at the peak. 100% had exanthema. The proportion of lymphadenopathy (31% vs 12%), fever (42% vs 29%), myalgia (35% vs 25%), and type of lesion: pustule (36% vs 27%), scab (25% vs 17%) and umbilicated lesion (24% vs 7%) was mayor in positive than negative case (p < 0.05). In the confirmed cases, the most frequent site of lesion was genital and anal area, 48% had multiple sexual partners and 14% having had contact with a positive case. 41% have a history of sexually transmitted diseases (HIV=39%). **Conclusions:** Main differences between confirmed and discarded cases were lesion features and distribution. Principal risk factors were previous contact with another positive case and multiple sexual partners. The current case definition seeks to be highly sensitive to capture the largest number of cases, being strategic at the beginning to detect an outbreak. We postulate that, for sustained epidemiological surveillance, a more specific definition in accordance with findings of current outbreak could be formulated.

A qualitative exploration of challenges in childhood TB patients identification and diagnosis in Bangladesh

Malabika Sarker¹, Sharmin Shitol², Sharmin Shitol², Avijit Saha², Mrittika Barua², Kazi Towhid³, Akramul Islam⁴

¹BRAC James P Grant School of Public Health, Bangladesh, ²BRAC James P. Grant School of Public Health, Bangladesh, ³National Tuberculosis Control Programme, Bangladesh, ⁴Communicable Diseases, Water, Sanitation, and Hygiene (WASH), Integrated Development, and Humanitarian Crisis Management, BRAC, Bangladesh

Background and Objective: As childhood TB is difficult to identify and diagnose, the experiences of the caregivers and healthcare providers of childhood TB patients remain a potential area of study. This study aims to illustrate the challenges caregivers and healthcare providers encounter in identifying and diagnosing childhood TB in two sub-districts of Bangladesh.

Methods: We conducted semi-structured in-depth interviews with eight caregivers of childhood TB patients and key informant interviews with 36 healthcare providers from July 2019 to June 2020 from different levels of the TB control program in Keraniganj (with high childhood TB cases notification), Faridpur Sadar (with low childhood TB cases notification), and Dhaka city.

Results: There is a dearth of understanding among caregivers about childhood TB. Passive case finding process and focus on cough during community mobilisation contribute to delay in childhood TB identification. The stigmatisation that caregivers anticipate and experience has an impact on their mental health and implies that there are misunderstandings about tuberculosis in the community. Furthermore, diagnostic dilemma among healthcare providers accounts for diagnosis delays. Some, but not all, institutions in different geographical locations provide free diagnostic tests and have GeneXpert devices. **Conclusions:** Awareness should be raised in the community on childhood TB. The identification and diagnosis mechanism of childhood TB should be strengthened to minimise challenges faced by the caregivers and the healthcare providers so that children with TB can have an early identification, diagnosis, treatment initiation, and successful completion of treatment. Overall, addressing the challenges would lead to better case identification and diagnosis.

Vaccination strategies against seasonal Influenza in long term care setting: lessons from a Mathematical Modelling study

Matteo Ratti¹, Diego Concina², Maurizio Rinaldi³, Ernesto Salinelli², Agnese Brisco⁴, Daniela Ferrante², Alessandro Volpe², Massimiliano Panella²

¹University of Eastern Piedmont, Italy, ²Department of Translational Medicine, University of Eastern Piedmont, Italy, ³Department of Pharmaceutical Science, University of Eastern Piedmont, Italy, ⁴Department of Studies for Economics and Business, University of Eastern Piedmont, Italy

Background: Despite specific vaccination campaigns, many outbreaks of seasonal influenza like illness (ILI) in long term care (LTC) facilities are occasionally reported. We explored the dynamics of influenza starting from real data collected from a nursing home located in Italy and a mathematical model. Our aim was to identify the best vaccination strategy to minimize cases among the guests. **Materials and Methods:** The model consists of a classical SEIR part describing the spreading of the influenza in the general population and a stochastic agent based model that formalizes the dynamics of the disease inside the institution. After a model fit of a baseline scenario, we explored the impact of varying the HCW and guests parameters (vaccine uptake and vaccine efficacy) on the guest attack rates (AR) of the nursing home.

Results: The aggregate AR of ILI in the nursing home was 36.4% (ward1 = 56%, ward2 = 33.3%, ward3 = 31.7%, ward4 = 34.5%). The model fit to data returned a probability of infection of the causal contact of 0.3 and of the shift change contact of 0.2. We noticed no decreasing or increasing AR trend when varying the HCW vaccine uptake and efficacy parameters, whereas the increase in both guest vaccine efficacy and uptake parameter was accompanied by a slight decrease in AR of all the wards of the LTC facility. **Conclusions:** We can conclude that a nursing home is still an environment at high risk of influenza transmission but the handover situation carry no higher relative risk. Therefore, additional preventive measures in this circumstance may be unnecessary. Finally, in a closed environment such as a LTC facility, the vaccination of guests, rather than HCWs, may still represent the cornerstone of an effective preventive strategy.

Diagnosis and treatment of febrile children in a Ghanaian hospital

Lydia Rautman¹, Benno Kreuels², Oumou Maiga-Ascofaré², Jürgen May², Ralf Krumkamp²

¹Infectious Disease Epidemiology, Bernhard-Nocht Institute for Tropical Medicine, Germany, ²Bernhard-Nocht Institute for Tropical Medicine, Germany

Background and Objective: While a large proportion of fever among children in sub-Saharan Africa is accompanied by malaria, malaria is not always the main cause of fever. In areas of high malaria prevalence, antimalarials are frequently over-prescribed. Our objective was to achieve a better understanding of malaria infection dynamics and hospital diagnoses in an area where malaria is highly endemic. **Methods:** The fever without source study was conducted 2013-2015 at Agogo Presbyterian Hospital (APH) in Agogo, Ghana. Febrile children under 15 admitted to the pediatric ward were recruited to the study. Demographic, clinical, and laboratory data were collected and analyzed descriptively and graphically in R.

Results: A total of 1503 admissions were included in the analysis. Malaria parasites were detected in a majority (59%) of patients but analysis of changes in practitioner diagnoses from admission to discharge revealed that sepsis and malaria were frequently over-diagnosed: almost one-third of malaria and over 80% of sepsis admission diagnoses were not confirmed at discharge. Among children with malaria parasites detected in the blood, 95% received antimalarial treatment and 52% received antibiotics. Among those without malaria parasites, 30% were given antimalarials and 95% were given antibiotics.

Conclusions: Adherence to World Health Organization guidelines for the management of malaria and clearer diagnostic guidelines for the diagnosis of non-malarial febrile illness are needed. Further development of these guidelines could improve hospital diagnoses, reduce delays in treatment, and minimize unjustified antibiotic prescription.

Toxigenic diphtheria cases in North Queensland, Australia

Allison Hempenstall¹, Jay Short², Valmay Fisher¹, Caroline Taunton¹, Annie Preston-Thomas³, Tonia Marquardt³

¹Torres and Cape Hospital and Health Service, Australia, ²Townsville Hospital and Health Service, Australia, ³Cairns and Hinterland Hospital and Health Service, Australia

Background and Objective: Diphtheria is predominantly caused by toxigenic *Corynebacterium diphtheriae* and presents as both respiratory and cutaneous disease. Locally acquired tox-gene-carrying diphtheria is rare in Australia and cases have all but disappeared from the country since the 1950s with widespread uptake of the diphtheria toxoid vaccine. Since 2018, there has been an increase in locally acquired cutaneous and respiratory cases of toxigenic C diphtheriae across North Queensland, Australia with whole genome sequencing of specimens identifying a genetically-linked cluster of cases in the region. Here we present the epidemiology of this outbreak.

Methods: We retrospectively reviewed all notifications of confirmed *Corynebacterium diphtheriae* cases occurring in the North Queensland region between 2000 and 2022. Demographic, clinical and exposure source details were extracted from Queensland Health's Notifiable Conditions System and laboratory typing results obtained from Queensland Health Forensic and Scientific Services. Data were de-identified and analysed using Microsoft Excel 2021. The Townsville Human Research and Ethics Committee approved the study.

Results: There have been 29 notified cases of genetically linked tox-gene-carrying diphtheria across North Queensland since 2020, 23 of which occurred in 2022. Three cases presented with classic respiratory diphtheria, four with mild respiratory diphtheria and 22 with cutaneous diphtheria. All infections were acquired in Australia and all cases had epidemiological links to the North Queensland region. A total of 86% of cases (25/29) identified as Aboriginal and/or Torres Strait Islander people. All cases were managed with penicillin or azithromycin, vaccination, and diphtheria antitoxin (DAT) where appropriate. Household contacts were screened for symptoms, administered chemoprophylaxis, and offered a diphtheria-containing vaccination if due.

Conclusions: This outbreak contributes to the broader global concerns for increasing diphtheria outbreaks. Timely vaccinations in children, adolescents, pregnant women, and eligible older people remain of upmost importance. Australian clinicians and public health professions should remain vigilant for future cases.

Facilitators and barriers to integrated malaria prevention in Wakiso district, Uganda: a photovoice study

David Musoke¹, David Musoke¹, Grace Biyinzika Lubega¹, Filimin Niyongabo¹, Suzan Nakalawa¹, Rhoda Wanyenze¹, Moses Kanya²

¹Makerere University School of Public Health "New Mulago Hospital Complex P. O. Box 7072, Kampala, Uganda" Uganda, ²Makerere University School of Medicine "New Mulago Hospital Complex P. O. Box 7072, Kampala, Uganda" Uganda

Background and Objective: Malaria continues to cause significant morbidity and mortality particularly in Sub-Saharan Africa. Appropriate combinations of non-chemical and chemical methods of malaria vector control in the context of integrated vector management have been recommended by the World Health Organization. Integrated malaria prevention, which promotes the use of several malaria prevention methods holistically, is being explored. The aim of the study was to explore facilitators and barriers to using integrated malaria prevention in Wakiso district, Uganda

Methods: The qualitative study employed photovoice among 20 community members in Kasanje Town Council, Wakiso District. The photos taken by participants for a period of 5 months using smartphones were discussed monthly with the researchers. The discussions were audio-recorded, and resulting data analysed using thematic analysis with the support of NVivo (2020).

Results: Various conventional and non-conventional measures were being used for preventing malaria such as: insecticide treated nets; clearing overgrown vegetation and draining stagnant water near houses; mosquito coils; smoldering of cow dung; spraying insecticides; plant repellents near houses; as well as closing doors and windows on houses early in the evening. Facilitators to using several malaria prevention methods holistically included: low cost and convenience of some methods such as slashing overgrown vegetation; and support provided for certain methods such as receiving free mosquito nets from the government. Barriers to using several malaria prevention methods holistically included: inadequate knowledge of some methods such as housing improvement; allergic reactions to chemical-based methods such as insecticide treated nets; unaffordability of some methods such as insecticide sprays; and inaccessibility of certain methods such as body repellents.

Conclusion: Several barriers to using integrated malaria prevention were identified. These barriers need to be addressed so as to contribute to malaria prevention efforts in endemic communities.

Outbreak investigation of cholera at district Quetta, Baluchistan 2022

Aabad Khan¹, Ehsan Larik¹, Rabia Baloch¹, Shahkoh Mengal²

¹Provincial Health Directorate, Balochistan FELTP Health Department, Balochistan Director General Health Services, Sariab Road Quetta, Pakistan,

²Health Department of Balochistan, Government of Balochistan, Civil Secretariate of Balochistan, Zarghoon Road Quetta, Pakistan

Introduction: Unusual occurrence of 10 suspected Cholera cases at Pashtoon Bagh Quetta were reported to Provincial Disease Surveillance and Response Unit Quetta on 18th May 2022. FELTP team was deputed to investigate and recommend preventive measures for outbreak.

Methodology: A descriptive followed by matched case control study was conducted to investigate Cholera outbreak at District Quetta. Case was defined as any person living at District Quetta who had suffered 3 or more, loose watery stool in last 24 hours from 18th May to 12th October. We reviewed hospital records and active case finding was conducted through house-to-house survey. Matched for age and sex neighborhood controls were taken with the ratio of 1:1 and interviewed. We collected stools and water samples for microbiological testing. We performed associated risk factor survey. We calculated Odds Ratios (OR) at 95% confidence interval (95% CI). Data was analyzed using Epi Info 7.

Results: We identified 48 positive Cholera cases. There were 28 (58%) hospitalizations. Males (67%) were more affected than females. Median age was 09 years (range: <1-61 years) with highest Attack Rate among <01-to-09-year old's (54%). Attack rate was 4.1/1,000,000 with 2% mortality rate. Drinking contaminated pipeline water was strongly associated (OR: 12.8, P value <.05, CI 4.9-33.7) with illness. While drinking Tube well water was protective (OR=0.12, 95%CI=0.05-0.29). The water samples of damaged water pipeline confirmed the fecal contamination and Cholera isolation from 10 samples out of 15.

Conclusion: This cholera outbreak was associated with drinking pipeline water likely contaminated after monsoon rains. Outbreak probably resulted from insufficient access to clean water & poor sanitation. A robust surveillance system placed with support of partners. Intersectoral response and WASH cluster activated. We conducted 30 health education sessions. OCV drive conducted based on this study recommendation. We recommended Sustained health education and provision of purified water.

Active provision of influenza vaccination in diabetic individuals aged 18-64 years in ASL Rome 1: experience and evaluation of results in the 2020-2021, 2021-2022 and 2022-2023 influenza vaccine campaigns

Mattia Macino¹, Marta Marino¹, Marta Marino¹, Mattia Macino¹, Fabiola Valentini¹, Raffaella Mosco¹, Sara Ciampini¹, Aurora Santagata¹, Paolo Maggolini¹, Patrizia Cortesi¹, Anna Zoppegno¹, Lelio Morviducci¹, Patrizia Chierchini¹, Gennaro D'Agostino¹, Antonietta Spadea¹

¹Azienda Sanitaria Locale Roma 1 Italy

Introduction: The Ministry of Health Circular "Prevention and control of influenza: recommendations for the 2022-2023 season" identifies diabetics as being at higher risk of contracting invasive infectious diseases and developing serious complications.

Materials and Methods: During the 2020-2021 flu season, influenza vaccination was actively offered to diabetic individuals aged 18-64 years.

GPs and pediatricians were invited to actively call their diabetic patients.

In the 2021-2022 flu vaccination campaign, mass mailing of letters via postal service was carried out to the 17,121 diabetic patients identified by the Lazio Region to promote their immunization.

Finally, a comparison was made with what was done in the three metropolitan Local Health Authorities (ASL Roma 1, 2 and 3).

The 2022-2023 immunization campaign is still ongoing and the results will be presented at the conference

Results: During the 2020-2021 influenza season, 3,624 subjects were vaccinated by GPs and vaccination centers.

In the 2021-2022 CVA, despite the general decline in adherence in all target categories, there was an increase in the absolute number of vaccinated diabetics with 4,437 subjects.

This figure corresponds to 15.18% of what was achieved in the Lazio Region, but when compared with what was achieved in the Roman ASLs (1, 2, and 3), the figure recorded in ASL Roma 1 corresponds to 34.44%, in line with the residence data.

Conclusions: In the light of the results achieved, we can affirm that the strategy of active calling of the target population, based on a principle of proximity, has proved successful and makes the need to create synergies with the territory to reach capillary the immunizable subjects more and more evident.

Influenza vaccination in healthcare workers in ASL Roma1: best practices, outreach offer, and trend assessment of CVA 2020-2021 and 2021-2022 and 2022-2023

Sara Ciampini¹, Antonietta Spadea¹, Aurora Santagata¹, Mattia Macino¹, Marta Marino¹, Francesca Speranza¹, Giuseppe Furia¹, Paolo Maggolini¹, Valentina Ungari¹, Anna Zoppegno¹, Andrea Barbara¹, Paolo Parente¹, Patrizia Chierchini¹, Gennaro D'Agostino¹, Raffaella Mosco¹, Antonietta Spadea¹

¹Azienda Sanitaria Locale Roma, Italy

Introduction: The Ministry of Health Circular "Prevention and Control of Influenza: Recommendations for the 2021-2022 Season" recommends influenza vaccination coverage for Health Care Workers of at least 75%, so as to ensure reduction of individual risk of illness, risk of transmission to individuals at high risk of complications/hospitalization, reduction of social costs related to morbidity and mortality and related absenteeism.

Materials and Methods: Informative/training meetings were held at all the corporate Presidia of ASL Roma1 to raise awareness of influenza vaccination among health care workers, and vaccination was actively offered and on site.

Results: During the 2020-2021 flu season, 18,753 health care workers were vaccinated in our Company out of a total of 50,798 vaccinated in the Lazio region, or 36.9%. Achieved coverage data were compared with those of the three ASLs in the urban area of metropolitan Rome, in which 34,996 workers were vaccinated. In the 2021-2022 flu season, there was a decline in the adherence of all target groups, including health workers: 10,586 vaccinated in our company out of 30,635 workers vaccinated in the region, or 34.56 percent. Following the same comparison with the three metropolitan Rome ASLs, the ratio was 53.3 percent. The 2022-2023 campaign is ongoing and the results will be presented at the conference

Conclusions: It is widely documented that health worker vaccination has multiple values: it reduces the infectious risk of workers, protects patients from infection in care settings, and protects the operation of care services. Therefore, it is a priority to encourage the co-administration of influenza and anti-SARS-CoV-2 vaccination, to encourage vaccination promotion policies aimed at increasing awareness of the risks associated with the disease, and to promote on-site vaccination, training and information events of health care workers by validating the 5 C model (Confidence, Constraints, Complacency, Calculation and Collective responsibility).

Epilepsy care in resources-constrained settings: the nodding syndrome alliance experience in three clinics in Western Equatoria, South Sudan

Beatrice Sgorbissa¹, Chiara Scanagatta², Jacopo Rovarini³, Stephen Jada⁴, Beatrice Sgorbissa², Francesca Tognon², Fabio Manenti², Giovanni Putoto²

¹Doctors with Africa CUAMM; Department of Public Health, University of Padova (ITALY), Italy, ²Doctors with Africa CUAMM Italy, ³Amref Health Africa Italy, ⁴Amref Health Africa South Sudan

Nodding Syndrome (NS) is a degenerative neurological disease with poorly understood etiology which mainly affects children in some regions of Sub-Saharan Africa. Since 2019, a consortium of NGOs (the "Nodding Syndrome Alliance"), led by Amref Health Africa, has been working with the Ministry of Health of South Sudan to respond to the multi-sectoral needs of people with epilepsy (PWE), including NS, in three counties of Western Equatoria. Three clinics were set up, at Lui Hospital, Maridi Hospital and Mundri Primary Health Care Centre, supported by Doctors with Africa CUAMM.

Descriptive statistical analysis was conducted from patients' databases maintained in Microsoft Excel at the clinics. Between May 2020 and August 2022, 3454 patients were enrolled, majority of them during the first year (increase of 160' of patient admissions from May 2020 to May 2021). Among all the patients, 963 (27.8%) were under 18 years old, the most represented age group was 15–24 (56.1%) and 48.2% were Female. 7 patients received a diagnosis of confirmed NS, based on the WHO case definition. Patients with probable NS accounted for 61.7% of the total (n. 2131), while the rest were diagnosed with other forms of epilepsy. Mortality rate among the enrolled patients was 1.3%. Carbamazepine was administered in 1906 (55.2%) patients, followed by Phenobarbital (787; 22.8%), Phenytoin (506; 14.6%) and Valproic Acid (252; 7.3%). The monthly average defaulter rate during the last six months of the project was 37.5%. Among all patients, 90% reported an improvement of their quality of life after receiving treatment (47% described it as much better and 43% as better) and 90% reported a reduction in seizures frequency. Epilepsy, including NS, represent a health, social and economic burden for the affected population. Further studies are needed to better investigate etiology, epidemiology, efficacy of treatments and prevention interventions.

DOI: 10.18332/popmed/163724

Global burden of anthrax: a systematic review

Carlotta Di Bari¹, Carlotta Di Bari¹, Christina Fastl¹, Brecht Devleeschauwer¹
¹Sciensano, Belgium

Background and Objective: Bacillus anthracis, the etiologic agent of anthrax, primarily infects herbivores and is transmitted to humans through contact with infected animal products. Despite its clinical impact, there is currently no global estimate of its disease burden. We aimed to identify incidence and clinical data to contribute towards calculating a Disability-Adjusted Life Years estimate for anthrax.

Methods: 14,146 articles published between January 1990 and December 2021 were identified from eight databases relating to human anthrax. In addition, we also reviewed international surveillance databases. We derived appropriate disability weights for anthrax from the Global Burden of Disease study.

Results: Sixteen studies from the review provided information on incidence, and 45 on clinical manifestations. Data were available for 30 countries in Europe, the Middle East, Sub-Saharan Africa, Asia and the Caribbean. Anthrax incidence varied widely between countries, ranging from 0.03 in Ghana to 1.4 in Georgia per 100,000 inhabitants. Based on the literature, we assumed that 95% of all cases are cutaneous and that the remaining 5% are gastrointestinal. For the disease model, we summarized the clinical manifestations into three main forms of cutaneous anthrax – mild (DW 0.074), moderate (DW 0.228), and severe (DW 0.597), and two health states for gastrointestinal anthrax – oropharyngeal (DW 0.223) and intestinal (DW 0.550). The duration was estimated following the same clinical manifestation, with a time frame between two for the less severe forms and eight weeks for the critical ones.

Conclusion: Epidemiological and clinical data are essential for accurate assessments of the burden of disease. For anthrax, urgent efforts are needed to fill in the missing data in developing countries, specifically focusing on the duration of the post-acute phase and underreporting. Meanwhile, an integrated approach to disease surveillance involving human health and veterinary services would allow for a better understanding of disease dynamics.

Immeuble Diplomate, 13ème étage, Tunisia, ²National Observatory of New and Emerging Diseases, Tunisia, ³National Observatory of New and Emerging Diseases, Full professor, 5-7 Rue Elkhartoum, Immeuble Diplomate, 13ème étage, Tunisia

Background and Objective: Hemodialysis Facilities (HF) are high-risk environments for the spread of Hepatitis C Virus (HCV). This study aimed to detect HCV in hemodialysis patients as part of the National Plan for the Elimination of VHC in Tunisia.

Methods: We conducted a national screening study in all HF from Mars 2021 to November 2022. Hemodialysis patients more than 18 years of age, were enrolled in this study. All samples were screened for HCV antibody by Enzyme linked immunosorbent assay (ELISA) and HCV RNA by Polymerase chain reaction (PCR). **Results:** A total of 11653 patients (mean age 56,8 years) from 187 HF were enrolled among them 9985 patients completed HCV screening (86,3%). The overall prevalence of HCV antibody was 3,2% ranging from 0% to 27,9% : 0% in 56 centers, 0,1 to 5% in 88 centers and more than 5% in 36 centers. The prevalence was 3,5% among Female and 3% among male. The mean age of positive patient was 57,3 years. Only 28,1% of HCV antibody positive patients were positive for HCV RNA by PCR.

Conclusion: Early detection of new HCV infection, the prevention of the infection transmission by the application of universal hygienic precautions program and the treatment of all screened patients are needed to achieve the objective of HCV elimination in Tunisia.

Determining levels of knowledge, worry, anxiety and intention to get vaccinated during the recent monkeypox outbreak: a cross-sectional study from the United Arab Emirates (UAE)

Basema Saddik¹, Rouba Zeidan², Ankita Shukla², Amal Hussein², Hamzah AlZubaidi², Mohamad-Hani Temsah³, Mohamed Alhajjaj², Najlaa Al-Bluw², Manal Awad², Hawra Alsayed⁴, Narjes Sharif-Askari², Zahraa AlHano², Qutayba Hamid², Raibh Halwani²

¹University of Sharjah, Department of Family and Community Medicine; Sharjah Institute of Medical Research; University of New South Wales-School of Population Health, United Arab Emirates, ²University of Sharjah, ³King Saud University, Saudi Arabia, ⁴Dubai Health Authority, United Arab Emirates

Background: Monkeypox cases increased in non-endemic countries in May 2022, raising global concerns. Past outbreaks of infectious diseases, including COVID-19, have been associated with several psychosocial effects due to a lack of knowledge and the rapid spread of misinformation and fear. In this study, we examined knowledge, worry, and anxiety levels among the general population about monkeypox, as well as their willingness to receive a vaccine.

Methods: An online cross-sectional survey of adults in the UAE was conducted in June 2022. Information on monkeypox-related beliefs, perceived risks, knowledge, worry, anxiety, previous COVID-19 infection and vaccination status, and willingness to receive a vaccine for monkeypox was collected. Bivariate and logistic regression analysis determined associations and predictors between dependent and outcome variables.

Results: A total of 959 participants were included in the analysis. A median knowledge score of (12/19) indicated suboptimal knowledge. Only a quarter of participants believed they were at high risk of monkeypox infection; however, 46% believed that infection would have a significant impact on their health, and 57% believed that fear of monkeypox in the community was justified. Knowledge scores were higher among women, healthcare workers, and those whose sources of information were considered reliable. Perceived high risk of infection, changes in precautionary measures, and belief that treatment would be difficult predicted higher levels of worry and anxiety among participants. Participants with higher levels of worry and who had received two or more doses of the COVID-19 vaccine were more likely to take a vaccine once it became available.

Conclusion: These findings demonstrate low levels of knowledge and high levels of worry and anxiety among the UAE population and highlight the need for raising public awareness regarding monkeypox and future outbreaks. Additionally, these findings will inform policymakers and health regulators on the promotion of vaccination campaigns.

Descriptive epidemiology of visceral leishmaniasis in Afghanistan, 2018-2022

Mohammad Tamim¹, Khwaja Saeed²

***Malaria and other Vector Borne Diseases Program of Afghanistan (MVDP), Head of Epidemiology and Surveillance of Malaria and other Vector Borne Diseases (MVDP) & AFETP fourth cohort resident, Darulaman Road, Sanatorium street, MVDP, Kabul, Afghanistan, *FETP, MoPH**

Background/Objective: Visceral Leishmaniasis (VL) is fatal if left untreated in 95% of cases. An estimated 50,000 to 90,000 cases of VL occur worldwide annually. Afghanistan is an endemic country for V. This study aims to illustrate the epidemiological profile of VL and report treatment outcomes in Afghanistan. **Methodology:** A descriptive study using secondary data was conducted to reflect the epidemiological profile of VL in Afghanistan. It covers period of 2018-2022 using a paper-based surveillance system at Malaria and other Vector Borne Diseases (MVDP) for VL cases. The study included 18 provinces with confirmed diagnosis. The treatment outcomes were collected by phone calls. Epi Info V7.2.1 was used for data analysis.

Results: Totally 77 VL cases were recorded during 2018-2022 of whom 48 (62%) were males. More than half of 45 (58%) were in age group of 1-3 years while 3 (4%) were in age group of 10-13 years. Geographically, 28 (36%) were reported from Faryab followed by Baghlan 9 (12%) compared to Ghazni 1(1.2%). Four (5%) and 7(9%) cases reported family member with cutaneous leishmaniasis VL respectively. Fever 75 (97%), splenomegaly 71 (92%) and weight loss 26 (34%) were common clinical manifestations. Upon follow-up, 42 out of 77 total cases responded of whom 31 (74%) were cured and 11 (26%) had died. Apparently, 22 (85%) with early diagnosis were cured compared to 9 (56%) with late diagnosis. **Conclusion:** Most of the cases were recorded from northern region with high burden in males. Splenomegaly was a prominent clinical feature. Early diagnosis had good outcome compared to late diagnosis. Further study is required to identify the risk factors. Additionally, access to diagnosis is recommended for the betterment of outcome.

Background and Objective: Poverty is a risk factor for HIV/AIDS but previous studies on the impact of conditional cash transfer programs (CCT) have shown inconsistent results. We evaluated the effects of one of the world's largest CCTs, the Programa Bolsa Família (PBF), on all sequential AIDS outcomes, using data from a nationwide cohort of the poorest Brazilian people on the Unified Registry for Social Programs (Cadastro Único).

Methods: We analyzed a cohort of 22.7 million low-income Brazilian people for the period between 2007 and 2015, comparing PBF beneficiaries and non-beneficiaries, using a quasi-experimental impact evaluation design. We used inverse probability of treatment weighting (IPTW) to adjust for selection into receipt of BFP benefits and then fitted multivariable Poisson regressions, adjusted for all relevant socioeconomic and demographic confounding variables, to estimate the effect of PBF on AIDS incidence, mortality, and case-fatality rates. We also performed subgroup analyses.

Results: Exposure to PBF was associated with a lower incidence of AIDS (RR: 0.59; 95% CI: 0.57-0.61), mortality (RR: 0.61; 95% CI: 0.57-0.64) and case-fatality rates

(RR: 0.75; 95% CI: 0.66-0.85). PBF associations were significantly stronger among individuals living in extreme poverty, in comparison with those experiencing poverty (RR0.53 versus RR0.84 for incidence; RR0.54 versus RR0.90 for mortality, and RR0.72 versus RR1.00 for case-fatality). PBF impact was also stronger among females and adolescents.

Conclusions: Conditional cash transfers could significantly reduce AIDS morbidity and mortality, especially in extremely poor populations. During the current dramatic rise in global poverty, due to the COVID-19 pandemic, CCT investments could protect against potential increases in the HIV/AIDS burden, and contribute towards achieving AIDS-related Sustainable Development Goals (SDGs).

(Funded by the National Institute of Allergy and Infectious Diseases - NAIDS/NIH, Grant Number: 1R01AI152938).

Tracking patient pathway for assessing public health and financial burden to community of Pulmonary Tuberculosis: Pointer from Central India

Dr Sinha¹

¹Pt. JNM Medical College Raipur, Ayush University Raipur Chhattisgarh, 401 A block aditya heights ring road 1 telibadha, India

Background: Pulmonary TB predominantly act as reservoirs of its transmission. Delays in seeking care may worsen the disease with increase risk to death. The National Tuberculosis Elimination Programme (NTEP) offers timely TB care without out-of-pocket expenses i.e. free diagnosis and treatment. Objective of this study was to document deferent delays in seeking TB care and calculate the out of pocket expenses pertaining to Pulmonary TB care in Raipur district of Chhattisgarh.

Material and Methods: This cross-sectional study was conducted among randomly selected 252 TB patients from Nov – Oct 2022 by taking in-depth interview following informed verbal consent. Their journey from initial symptoms until they reached the public health facility and their 'out-of-pocket expenditure' (OOPE) pertaining to TB care were documented.

Results: Total TB care delay on average was 91±72 days, while isolated patient delay 31±45 days (median: 15 days, IQR: 0 days to 43 days); diagnostic delay; 57±60 days (median: 42days, IQR 14-78 days), treatment delay 19 ± 18 days (median: 15days, IQR: 11-19 days). A patient delay (> 30 days) was significantly associated with ignorance about classical symptoms of pulmonary TB, adoption of self-medication, illiteracy, and middle and lower social class. Diagnostic delay was significantly higher among those who contacted private health facilities, were unaware of signs and symptoms, had more than 2 consultations and not getting an appropriate referral for TB care. Almost all (97%) had Out of Pocket Expenses (OOPE) with median total expenses were INR 6155 (IQR: 2625-15175) and were showed upward trend with delays in seeking care. (r =1).

Conclusion: Delay in TB care due to low awareness about signs and symptoms of TB and poor seeking care, lack of proper consultation and appropriate referrals with out of pocket expenses leads to remarkable public health and financial burden is still in unacceptable range.

Background: In Lombardy (a region in northern Italy, 10 million inhabitants), a network of public health and clinical laboratories was established to tackle and respond to emerging human infectious diseases. This study aimed at: 1) detecting and investigating the role of EVD68 in respiratory infections in Lombardy from July-2021 to November-2022; 2) describing the epidemiological features of EVD68.

Methods: From July-2021 to November-2022, respiratory samples were collected from: i) outpatients with influenza-like illness (ILI) in the framework of influenza surveillance network, ii) inpatients with severe acute respiratory infection (SARI) in 8 hospitals in Lombardy. Samples were tested for EV-RNA by all virological laboratories; the EV-positive sample were promptly tested for EVD68 by 2 second-level laboratories.

Results: 347 laboratory-confirmed EV-positive samples were detected: 139 from ILI and 208 from SARIs. EVD68 was identified in 38.6% (n=134) of EV-positive specimens. EVD68-positive individuals had a median age of 3 years (IQR: 4.5 years). EVD68-positive rate among SARI cases was statistically higher than that observed in ILIs (46.2% vs. 27.3%; $p < 0.0001$), with a risk of infection from EVD68 3-fold higher (OR:3.0; 95%CI:1.9-4.8) in SARIs than in ILIs.

EVD68 circulated with two consecutive epidemic waves. The first wave – accounting for 25% of EVD68s – started in September-2021, peaked at end of November, ended in March-2022; the second wave – accounting for 72.6% of EVD68s – started in July-2022, reached a peak in the beginning of October-2022 and is still ongoing.

Conclusion: The tight collaboration and close networking of public health and clinical laboratories allowed disclosing in real-time two EVD68 outbreaks in Lombardy over the last year. A greater contribution of EVD68 was observed in SARIs than in ILIs. Collaboration and networking of public health and clinical laboratory through molecular surveillance need to be advocated and endorsed as a successful key strategy to uncover and respond to emerging pathogens.

Respiratory Syncytial Virus: a preliminary analysis of epidemiological data in Verona University Hospital

Nicola Sorio¹, Diana Dalla Valle¹, Adele Olivieri¹, Silvia Colpo¹, Francesco Zunino¹, Francesca Moretti¹, Stefano Tardivo¹

¹University of Verona, Italy

Background and Objectives: In the United States (US), an unexpected wave of Respiratory Syncytial Virus (RSV) has hit pediatric wards in 2022. In November 2022, a seasonal increase in RSV cases is also observed in Europe. The present work is a preliminary analysis on the epidemiology of RSV, using data from the Integrated University Hospital of Verona (AOUI VR). We compared the epidemic curve in the 2022-2023 season with the previous ones. Furthermore, the temporal trend will be compared with the current primary epidemiological data (European Centre for Disease Control ECDC and Centre for Disease Control CDC).

Methods: Data about number of RSV-positive patients were collected via Hospital Discharge Forms of AOUI VR (ICD9-CM diagnosis codes: 079.6, 480.1, and 466.11). We analyzed seasons from 2018-2019 to 2022-2023, with specific focus on the 0-4 age group. ECDCs Atlas platform and CDCs RSV-NET interactive dashboard were compared.

Results: In 2018-2019 and 2019-2020, the trend of the AOUI RSV remained similar over time: an abrupt start of the epidemic was observed in December, followed by a peak of about 40 monthly hospitalized cases in January and a significant decline in March. Conversely, in 2020-2021, no RSV cases were hospitalized in AOUI. The epidemic resumed in the 2021-2022 season, starting in October, peaking in November and ending in January. In contrast, the first cases of the 2022-2023 season were already detected in September, without any significant increase (<5 new cases monthly) until now. Data collection is in progress.

Conclusions: Although the RSV epidemic season is still ongoing, differences between 2018-2023 AOUI data and the epidemic trend in the US are detectable. Given these preliminary results, an increased focus on acquiring additional data through a dedicated national surveillance network could significantly improve RSV epidemic management.

Tuberculosis in the Local Health Authority (LHA) of Cagliari: study of epidemiology for a qualitative approach to the prospects of improvement in public health management

Wisam Salameh¹, Alberto Lai², Maria Zedda¹, Serenella Secci², Federica Schirru², Alessia Raggio², Martina Lallai², Alessandra Murgia²

¹University of Cagliari Italy, ²ASL Cagliari Italy

Materials and methods

An anonymized database of TB cases was created. The cases were reported through the notification forms and received by the LHA of Cagliari from 2017 to 2021, carrying out a descriptive statistical analysis of the data.

Results: 307 notification forms were received (average incidence of confirmed cases 2.44/100,000 inhabitants per year) with an average age of 45, male prevalence and Italian citizenship over foreign citizenship. The median between the day of onset of symptoms and the start of therapy is 47 days: it is higher in those born in Italy than in those born abroad (67 days vs 27 days). In most cases, no treatment monitoring report was received from the physician.

Conclusions: The epidemiological study on the spread of Tuberculosis, particularly among the categories at risk, is one of the LHA's priorities. The diagnostic delay, particularly for those born in Italy, presents a data higher than the Italian average and the target value set by international organizations: the LHA of Cagliari intends to propose a study with a qualitative approach on the attitudes and knowledge of general practitioners in order to organize a training course aimed at the needs identified. The lack of data on the outcome of the treatment underlines the need to share a health care procedure with an ad hoc public health measure.

Reporting trends of measles cases in Italy, January 2013 to November 2022, and progress towards elimination

Martina Manso¹, Antonietta Filia¹, Maria Rota¹, Antonino Bella²

¹Istituto Superiore di Sanità Italy, ²Istituto Superiore di Sanità Italy Italian measles epidemiological surveillance network Italian local and regional health authorities Italy

Background and Objectives: Measles is a vaccine-preventable contagious acute viral illness targeted for elimination in all six WHO Regions. Elimination requires high two-dose vaccination coverage in the population. In Italy, vaccination uptake in 2021 was 93.8% among two year-old children (one dose) and 85.6% for two doses at 5-6 years. Measles cases are reported to the national integrated measles and rubella surveillance system, implemented in 2013 and coordinated by the National Health Institute. The aim of this study is to describe measles epidemiology in Italy in the last decade.

Methods: We analyzed reporting trends in measles cases with symptom onset during January 2013 to November 2022.

Results: During 1 January 2013 to 30 November 2022, 14,913 measles cases were reported to the Italian national integrated measles and rubella surveillance system, of which 2,270 in 2013, 1,695 in 2014, 256 in 2015, 862 in 2016, 5,397 in 2017, 2,683 in 2018, 1,622 in 2019, 105 in 2020, 8 in 2021 and 15 in 2022. Epidemic peaks of over 300 cases occurred in the months of June 2013 and January 2014, March 2017 (973 cases), April 2018 (495 cases) and April 2019 (309 cases). From May to December 2019 there was a progressive decrease in the number of reported cases but an increasing trend was observed in the first months of 2020, followed by a drastic decline during the COVID-19 pandemic (range 0-4 monthly cases from April 2020 to November 2022). Overall, 74% of reported cases were laboratory confirmed, 13% of cases were probable cases and 13% were classified as a possible cases.

Conclusion: Widespread circulation of measles occurred in Italy during 2017 to 2019, as in other EU/EEA countries. This was followed by an abrupt decrease in the number of reported cases since April 2020. Measles vaccination coverage remains suboptimal.

An unusual outbreak of acute infectious gastroenteritis

Fionn Donnelly¹, Eimear Burke²

¹Department of Public Health, South East St Canice's Hospital Lacken Co. Kilkenny Ireland, ²Department of Public Health, South East

Introduction: We present the case of a large outbreak of gastroenteritis with a food and beverage premises as the source. This outbreak had more than 100 suspected cases although only a sample of these were tested and interviewed by Public Health.

Case description

This investigation was prompted by several complaints of acute gastrointestinal illness made by members of the public to the Environmental Health service and the Food Safety Authority of Ireland. All complaints had a common exposure history and the majority had symptoms which developed within 48 hours of being in the premises. Initial investigations identified contaminated water and ice as the likely source of infection and a further rapid case/control study confirmed this.

The premises were fully inspected by the local council and Environmental Health officers and the water supply was found to have extremely high levels of bacterial contamination. This was despite the fact that the water supply to the premises came from the local mains water supply and not from a private well. The premises in question did have a private well but water from this was only used for watering plants and washing outdoor equipment according to the business operator. Of the stool samples tested from affected patrons, five were positive for Norovirus, and none had evidence of bacterial infection.

Discussion

This outbreak presented a particular challenge to the Health Protection team as due to the scale of the outbreak it was impossible to interview and test all of those affected. In addition, despite only isolating Norovirus from the stool samples, it seems improbable that the levels of bacterial contamination seen in the water samples would not have been responsible for much of the illness caused.

High consequence infectious diseases in Europe - the need for an expert clinical support service

Arne Brantsæter¹, Svein Henriksen², Catherine Leport³, Bente Lund⁴, Ingebjørg Skrinde², Marta Mora-Rillo⁵, Timo Wolf⁶, Jake Dunning⁷, Francesco Vairo⁸

¹Oslo University Hospital Department of Acute Medicine and Department of Infectious Diseases Norway, ²Directorate of Health, ³Paris Cité University Infectious diseases, 1137 research unit France, ⁴Directorate of Health Norway, ⁵La Paz University Hospital IdiPAZ, CIBER-Infec Spain, ⁶Universitätsklinikum Frankfurt Medizinische Klinik II, Infektiologie Germany, ⁷Royal Free NHS Foundation Trust Department of Infectious Diseases United Kingdom, ⁸National Institute for Infectious Diseases, Italy

Background and objective: During the 2014 Ebola virus disease outbreak in West Africa, the Centers for Disease Control and Prevention and the World Health Organization hosted telephone conferences for an ad hoc network of clinicians involved in the care of medically evacuated patients to Europe and the US. This informal network has also proved valuable during subsequent outbreaks and has revealed the need for a digital communication platform for clinical consultation and information sharing. Work package (WP) 10 of the EU Joint Action SHARP addresses case management and infection prevention and control in response to high consequence infectious diseases (HCIDs). Among the WP activities, a feasibility study of an expert consultation platform for HCIDs is ongoing. Here we report our preliminary results.

Methods: We searched literature for references to existing digital platforms and consulted colleagues and authorities in Europe about their experiences. We solicited legal and technical advice, and drew on experiences from the COVID-19 pandemic.

Results: The use of a digital expert clinical support service remains challenging with respect to availability of technical solutions, legislation, and funding. A digital platform should feature facilities for clinical consultations and information sharing among experts, but may also provide a channel for other requests, e.g. international referral, and deployment of equipment, staff, and therapeutics. The European Reference Network (ERN) operates a digital platform that has many of the required features. Some legal challenges remain, but these may be resolved by further development of European Health Union legislation, e.g. the European Health Data Space.

Conclusion: There is a need for a formal network of European clinicians with expertise in HCIDs, a need for a digital platform meeting defined technical and legal criteria, and a need for long-term funding. One solution could be to establish a new clinical network for HCIDs within the ERN.

Multi-country Viral Hepatitis COMMunity Screening, Vaccination, and Care (VH-COMSAVAC): Project outline

Angelo Pezzullo¹, Pietro Lampertico², Camila Picchio³, Leonardo Villani¹, Domenico Pascucci¹, Roberta Pastorino¹, Matteo Pumpo¹, Lena Van Selm³, Delfina Boudou³, Davide Fortin³, Giorgos Kalamitsis⁴, Giuseppe Colucci², Antonio De Belvis¹, Carlo La Vecchia⁵, Stefania Boccia^{1,1}, Jeffrey Lazarus^{1,1}

¹Università Cattolica del Sacro Cuore Italy, ²Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Italy, ³Barcelona Institute for Global Health (ISGlobal) Spain, ⁴Hellenic Liver Patients Association "Prometheus" Greece Massimo Colombo Hospital San Raffaele Italy, ⁵University of Milan, Italy Chronic viral hepatitis infection caused by hepatitis B and C viruses (HBV and HCV) is a major public health challenge. In high-income countries, HBV and HCV

infections are more prevalent among marginalized communities, such as migrants and refugees. The EU4Health program has funded Multi-country Viral Hepatitis COMMunity Screening, Vaccination, and Care (VH-COMSAVAC) to reduce the liver cancer burden caused by HBV and HCV infections in the European Union (EU). In line with "Europe's Beating Cancer" plan, the project seeks to leverage established partner networks offering community-based HBV and HCV screening and appropriately link people to specialist care and vaccination. An economic assessment of the impact and value of these interventions on the liver cancer burden will be performed to inform future policies and guidelines. VH-COMSAVAC activities will take place in three EU member countries: Greece, Italy and Spain. The project employs effective and established community-based care models for hard-to-reach, marginalized populations, specifically migrants and refugees, to adapt and scale up early HBV and HCV screening using simple and innovative diagnostic tools, decentralized vaccination against HBV and linkage-to-care with hospitals specializing in the treatment of viral hepatitis. It is expected that migrant and marginalised populations included in the project will benefit by knowing their HBV and HCV status, being offered the first dose of the HBV vaccine in situ if appropriate, and being provided with an expedited referral to specialist care for treatment initiation and management if needed. Process, outcome, and cost indicators will be collected. The results of the community-based screening program will provide evidence to inform guidelines for tailored, person-centred models of viral hepatitis care. The results obtained from the interventions will provide clinical and economic effectiveness data to contribute to developing a roadmap to reducing the liver cancer burden associated with HBV and HCV infections in the EU.

The implementation of the international health regulations on vector-borne diseases - a scoping review of the qualitative evidence performed worldwide

José Durão¹, Carlos Quelhas², Inês Subtil³, Tiago Adrego⁴, Ana Alho⁵

¹Public Health Unit - Almada-Seixal Health Centres Cluster Public Health National School (NOVA University Lisbon) Portugal, ²Public Health Unit - Arco Ribeirinho Health Centres Cluster, ³Public Health Unit - Loures-Odivelas Health Centres Cluster Public Health National School (NOVA University Lisbon) Portugal, ⁴Public Health Unit - Pinhal Interior Norte Health Centres Cluster Public Health National School (NOVA University Lisbon) Portugal, ⁵Public Health Unit - Lisboa Norte Health Centres Cluster

Background and objective: The International Health Regulations were created by the World Health Organization with the purpose of preventing the international spread of diseases. The 196 signatory countries are bound by this international agreement. In this article we performed a review of the literature on the implementation and operationalization of measures at a continental and national level to prevent the spread of vector-borne diseases. The purpose was to understand the main strategies and policies adopted and how they have been operating.

Methods: Out of an initial search on PubMed[™], SCOPUS[™] and Web of Science[™] using combinations of "International Health Regulations" and "vector-borne diseases", 75 references were obtained, of which 27 were included after careful qualitative analysis.

Results: Included articles ranged from 1996 to 2022. Four major categories of measures were found: a) Surveillance and Epidemic intelligence; b) Declaration of Public Health Emergency of International Concern; c) Measures in Points of Entry; and d) Vaccination status. Implemented measures were found in all continents: Africa, Oceania (Australia), Asia (China, India, Taiwan), Europe (Ireland, Netherlands and Mediterranean countries) and North (USA) and South America (Brazil). Yellow fever, Zika, Dengue and Chikungunya were the most cited vector-borne diseases but Crimean Congo haemorrhagic fever, Japanese encephalitis, Lyme disease, Malaria, Leishmania, Tick-borne encephalitis and West Nile fever were also mentioned.

Conclusion: There are severe asymmetries across countries on the implementation of international regulations with regards to vector-borne diseases, particularly on the issue of surveillance systems. State Parties should consider the lessons learned from the pandemic and perfect their core capacities to prevent future outbreaks of infectious diseases.

Popul. Med. 2023;5(Supplement):A275

DOI: 10.18332/popmed/164442

Monkeypox outbreak: observational analysis of confirmed human monkeypox virus cases in the province of padua

Marco Pierbon¹, Chiara Vivian², Caterina Annicchiarico³, Elena Zambon³,

Lorena Gottardello², Tiziana Coppola³, Francesca Scotton³, Luca Sbrogì³

¹Health Local Unit n.6 Euganea Department of Prevention, Health Local Unit n.6 Euganea Via E. degli Scrovegni, 14 - 35131 Padova Italy, ²Health Local Unit n.6 Euganea, ³Health Local Unit n.6 Euganea Department of Prevention, Health Local Unit n.6 Euganea Italy

Background and objective: In June 2022, the first case of Monkeypox (MPX) was recorded in the Province of Padua. The behavioral and clinical characteristics of MPX cases obtained through epidemiological investigations and contact tracing performed by the Public Health Hygiene Service (SISP) of the Health Local Unit Euganea are described.

Methods: In the observational study, cases with PCR confirmation and contacts identified between 6th June and 19th September 2022 have been considered.

Results: Monkeypox virus infection was confirmed in 26 individuals, 92% of them were identified as men who have sex with men (MSM). The mean age was 37 years. The estimated incubation period was 8 days (95%CI:7-10). 5 cases were epidemiologically linked to case 0 (excluded from the study), a Spanish tourist. 5 cases were imported from Spain or UK. 15 patients (55%) were autochthonous, but only 4 with epidemiological link. 13 patients (50%) met the index case through dating apps, 6 in MSM clubs. 77% of patients (n.20) declared multiple/anonymous sexual activity, of these the mean of high-risk contacts per patient is 0.45. Prodromal symptoms were detected in 50% of cases. All cases (n.26) presented skin lesions, of which 92% anogenital and 50% hand/forearm. Lymphadenopathy was detected in 62% of cases. The mean time between the first symptoms and the diagnostic confirmation was 6 days (95%CI:4-7), the recovery was 21 days (95% CI: 17-26).

Conclusion: The MPX outbreak in the Padua MSM community reflected the international epidemiology. The high proportion of anogenital lesions confirm the MPXV transmissibility during sexual activity. The time delay between prodromal symptoms and diagnosis can be attributed to their non-specificity. Skin lesions were being the main factor in accessing the Infectious Diseases department. Stigma and fear of media exposure may reduce contact tracing compliance, particularly in patients who report intense risky sexual activity.

Popul. Med. 2023;5(Supplement):A277

Costs of prevention programmes: a comparative analysis of screening campaigns including HCV

Danilo Cereda¹, Sara Piccinelli², Riccardo Vecchio³, Giovanni Cicconi², Roberta Lattanzio², Gaia Ferraguzzi², Chiara Marrocu², Silvana Castaldi², Sudwaric Sharma², Anna Odone², Catia Borriello²

¹Regione Lombardia Italy, ²Università degli Studi di Milano Italy, ³Università degli Studi di Pavia

Background and objective: In June 2022, Lombardy Region started a new screening campaign for HCV. Ministerial and WHO guidelines on this subject indicate this screening as cost-effective according to data in the literature. Having ascertained, however, that cost-effectiveness ratios can be debated and that in any case the available resources are limited, we wanted to verify the real cost of the screening programme and compare it with the prevention programmes currently active.

Methods: The costs of each healthcare service were obtained from the 2022 tariff nomenclature. The number of level I, II and III services according to the screening pathway were obtained from the data contained in the 2015 Regional Report on cancer screening (for breast, colon and cervix), containing invitations, adhesions and recall rates, as well as the number of diagnoses (detection rate).

A cost of EUR 0.50 per invitation letter was also estimated for colon, cervix and breast screening.

Data on HCV screening were obtained from the dedicated software, from June 2022 to the end of November 2022.

Results: Breast screening had a total cost of 17,474,067 euro with 1,624 diagnosis. Colon screening had a total cost of 4,868,244 euro with 9,236 diagnosis.

Cervix screening had a total cost of 1,488,672 euro with 899 diagnosis.

HCV screening had a total cost of 992.400 euro with 104 diagnosis.

Therefore, per 100.000 euro invested we can estimate the diagnosis of: - 10,17 breast cancer - 189,72 colon cancer or adenoma - 59,72 cervix dysplasia - 10,48 HCV positivity

Conclusion: HCV screening proves to be cost-effective compared to other prevention programmes active in Lombardy Region. It would be interesting to compare them with the costs of vaccinations by taking into account the cases prevented, starting with the prevalence rate in the pre-vaccination period

Popul. Med. 2023;5(Supplement):A278

Rapid blood sample screening test for hepatitis c virus: Results of

nine months of activities

Giacomo Scaioli¹, Annalisa Castella², Roberta Siliquini², Angela Gallone³, Giulia Fornaro², Elena Lonardelli², Nigina Alimardanova², Giuseppina Moro⁴, Davide Minniti⁵, Franca Dall'Occo²

¹University of Turin 1) Department of Public Health Sciences, University of Turin, Italy 2) Local Health Authority ASL TO3, Piedmont, Italy, ²Local Health Authority ASL TO3, Piedmont, Italy, ³University of Turin, ⁴University of Turin Department of Public Health Sciences, University of Turin, Italy, ⁵Local Health Authority ASL TO3, Piedmont, Italy Health Director Italy

Background and objective: In recent years, an effective treatment for chronic Hepatitis C has been implemented. Therefore, screening programs to detect the Hepatitis C Virus were implemented, with the aim of treating chronic hepatitis C and reduce the incidence of this disease. Objective of this study is to analyze the results of a nine month period of HCV screening in a Local Health Authority located in Piedmont, Italy.

Methods: The screening program involved all the residents within the territory of the Local Health Authority, including temporary resident migrants, born between 1969 and 1989, for a total of around 157,000 subjects, who were contacted through a letter, and invited to outpatient clinics. A catch-up strategy, involving all the healthcare professionals of the National Health Service, was also implemented, e.g. during routine vaccinations, routine blood tests, or outpatient visits. The screening was executed through a rapid capillary or venous blood sample test. In case of positive results, HCV RNA was searched to confirm the results.

Results: Between 19th March 2022 and 10th December 2022, a total of 24,800 subjects were invited (mean age 43.5 yrs, standard deviation ± 2.8). A total of 3,957 capillary blood sample tests and 333 venous blood sample tests were executed (17.3% of the invited subjects, mean age 44.9 yrs, standard deviation ± 2.1). Seven subjects resulted HCV-positive, and four of them were confirmed positive through the HCV-RNA test (0.1% of the tests). All the positive subjects were referred to hepatologists.

Conclusions: Hepatitis C screening is an effective method to detect and eradicate HCV. However, to achieve these goals, it is mandatory to improve the adhesion rate. General Practitioners should play a pivotal role in this regard. Promotional campaigns at a local, regional and national level addressed to the general population, and especially to high-risk subjects, should also be implemented.

DOI: 10.18332/popmed/164369

Impact of a conditional cash transfer program on tuberculosis incidence, mortality, and case fatality-rate in a cohort of 53 million individuals

Daive Rasella¹, Gabriela Jesus², Andrea Silva², Priscilla Sacff², Iracema Lua²

¹Federal University Bahia Italy, ²Federal University Bahia Brazil

Background objective

Tuberculosis (TB) is considered a disease related to poverty, in fact, a higher burden of TB is often observed in populations with low socioeconomic status. During the current COVID-19 pandemic, a substantial increase in the global TB burden, caused by disruption of TB health services and increased poverty, has been predicted. Therefore, social interventions such as conditional cash transfers (CCT) can be effective in mitigating the effect of the pandemic on TB. We estimated the effect of PBF on TB incidence, mortality, and case fatality rate using a national cohort of 53 million individuals.

Methods: We analyzed individuals who entered the Cohort of 100 Million Brazilians between 2004-2015 and compared BFP beneficiaries and non-beneficiaries. We used multivariate Poisson regressions, adjusted for all relevant demographic and socioeconomic variables, and weighted with inverse probability of treatment weight (IPTW). We also perform a wide range of stratifications and sensitivity analyses.

Results: Exposure to PBF was associated with lower rates of TB incidence (RR:0.59, 95% CI: 0.58-0.60) and mortality rates (RR:0.69, 95% CI:0.65-0.73), was positively associated with a decrease in TB case fatality rates – although not statistically significant. Individuals living in extreme poverty had a greater impact of the PBF compared to less poor, (RR:0.49 versus RR:0.95 for incidence; RR:0.60 versus RR:1.00 for mortality and RR:0.80 versus RR:0.92 for fatality rate).

Conclusion: CCT can significantly reduce tuberculosis incidence and mortality, especially in extremely poor populations, by decreasing the unequal distribution of the TB burden in the most vulnerable populations, essential at this time with the dramatic increase in global poverty due to the COVID-19 pandemic, therefore, such a strategy can help protect against increases in the incidence of TB worldwide and contribute to achieving the goals of the "End TB Strategy".

Risk factors associated with COVID-19 deaths in hospitalized patients between March 2020 and March 2021 in Morocco Taza province case: Case control study

Bennasser Samira¹

¹Delegation of Public Health, FETP Morocco, Morocco

Introduction: Coronavirus disease (COVID-19) occurred for the first time in China in December 2019, particularly in the WUHAN city, then, it has spread rapidly around the world. To refine surveillance recommendations for this disease, this study was conducted to identify risk factors associated with deaths among COVID-19 patients in Taza Moroccan province between March 2020 and March 2021.

Methods: This is a retrospective case-control study among patients with coronavirus infection and hospitalized at the IBN BAJA provincial hospital in Taza from March 2020 to March 2021. The cases are patients who died. Three controls from the same cohort, hospitalized at the same time but declared cured on discharge, were matched to each case. Data analysis was performed using Epi-Info version 7 software. The analysis of the association was carried out by the statistical tests.

Results: This study included 94 cases and 282 controls. The mean age of cases and controls was 65 years (SD=11), the sex ratio M/F was 2.9 and 1.31 respectively in cases and controls. Others Factors such as older age (AOR=2.44 95%CI[1.28-4.66], male sex (AOR=2.91), Lung Injury greater than 70% on admission (AOR=5.26, 95%CI[2.71-10.2]), Time between onset of illness and hospitalization greater than 7 days (AOR=4.47, 95%CI[2.25-8.91]), the cardiac pathologies (AOR=4.41, 95%CI[1.85-10.5]), the blood sugar greater than 2g/l on admission (AOR=3.10, 95%CI[1.43-6.75]) were significantly associated with the death.

Conclusions: This study provides a comprehensive overview of the profile of COVID-19 hospitalized patients in Taza province and mortality risk factors. Keywords: COVID-19, SARS-COV-2, clinical features, prognostic factors

Epidemiology of and factors associated with Chlamydia trachomatis in fertility treatment-seeking patients in the Abu Dhabi Emirate, United Arab Emirates

Rami Al-Rifai¹

¹Institute of Public Health, College of Medicine and Health Sciences, United Arab Emirates University, Al Ain, United Arab Emirates

Background and Objectives: The burden of infection with C. trachomatis in fertility treatment-seeking patients in the United Arab Emirates (UAE) is still unclear. This study measures the seroepidemiology of C. trachomatis and investigates factors associated with seropositivity to C. trachomatis in fertility treatment-seeking patients in Abu Dhabi Emirate, UAE. Methods: A consecutive sample of fertility treatment-seeking patients completed a self-administered questionnaire and screened for C. trachomatis IgG, IgM, and IgA antibodies. Prevalence of lifetime (IgG positive), current/acute (IgM positive), and ongoing progression of infection (IgA positive) infection with C. trachomatis was quantified. Independently associated factors with seropositivity to C. trachomatis were identified.

Results: A total of 308 patients (mean age: 36.1 ± 6.8 SD, years) were surveyed. 87.7% of the patients were females, 93.4% married for >1 year, and 68.1% were infertile for ≥6 months. Of the patients, 19.0%, 5.2%, and 1.6% were with lifetime exposure, acute infection, and ongoing progression of infection with C. trachomatis, respectively. Overall, 22.0% of the patients were exposed to C. trachomatis. Males compared to females (45.7% vs 18.9%, p<0.001) and current/ex-smokers compared to non-smokers (44.4% vs 17.8%, p<0.001) carried higher seropositivity. Patients with a history of pregnancy loss also carried higher seropositivity compared to patients with no history of pregnancy loss (27.0% vs

16.8%, p<0.001), particularly recurrent pregnancy losses (33.3%). Independently, current smokers (ORa: 3.8, 95% CI: 1.32–11.04) and patients with a history of pregnancy loss (ORa: 3.0, 95% CI: 1.5–5.8) had significantly higher odds of infection with C. trachomatis. Conclusion: One in five and five in twenty fertility-treatment-seeking patients exhibited evidence of lifetime and current infection with C. trachomatis, respectively. This high prevalence of C. trachomatis in fertility treatment-seeking patients, particularly in patients with a history of pregnancy loss, possibly contributes to the growing burden of infertility in the UAE.

Environment friendly vector control (Slash and clear) to accelerate onchocerciasis elimination in a high transmission area: a pilot study in the Mbam valley (Centre Region, Cameroon)

André Domche¹, Hugues Djeunga², Philippe Nwane³, Michel Boussinesq⁴, Sébastien Pion⁴, Joseph Kamgno⁵

¹Centre for Research on Filariasis and other Tropical Diseases, University of Yaoundé I, Yaoundé, Cameroon, ²Centre for Research on Filariasis and Other Tropical Diseases, Cameroon, ³Centre for Research on Filariasis and other Tropical Diseases, Cameroon, ⁴Institut de Recherche pour le Développement (IRD), France, ⁵Centre for Research on Filariasis and Other Tropical Diseases, Cameroon

Background: Although “slash and clear” (slashing and clearing trailing vegetation where blackflies breed) has already proven its effectiveness in reducing blackfly densities in low transmission foci, the feasibility and impact of this strategy in very high transmission foci with large rivers and important vector densities is yet to be demonstrated.

Objective: To evaluate the impact of “slash and clear” approach on blackfly densities and onchocerciasis transmission.

Methods: Two first-line villages (Bayomen used as control site and Biatsota used as intervention site) where selected in Centre Region of Cameroon. In each village, baseline data were collected for one year, using human landing catching method. Two days of ground and boat prospection was done, for the identification and characterization of blackflies breeding sites. The “slash and clear” was conducted once a month during nine months. Generalized estimating equations were used to evaluate the effect of intervention, adjusted on baseline data.

Results: Prior to intervention, a total of 56870 and 51240 blackflies were collected in Bayomen and Biatsota, respectively. No significant difference was found between the two villages (p= 0.7545). The main attachment points for the blackfly larvae were the plant Pandanus candelabrum (90% of larvae/pupae). After the intervention (destruction of the blackfly habitat) period, blackfly densities declined from 51240 to 25520 in the intervention site (50.2% reduction) while in the control site, the densities declined from 56870 to 49471 (13% reduction); the observed reduction was significantly more important in the intervention site compared to the control site (p=0.0213).

Conclusions: This study revealed that the “slash and clear” approach has a significant impact on vector densities in a very high transmission setting. Additional studies are needed to investigate the long-term impact of the “slash and clear” strategy, and how it can be used to supplement mass drug administration to accelerate the onchocerciasis elimination.

Effect of multi-month dispensing on adherence to antiretroviral therapy among adolescents and young adults Tanzania

Heri Masuka¹

¹University of Dodoma, Dodoma, Tanzania

Background: Service delivery models for differentiated care provide a balanced approach to HIV services using longer dispensing intervals for patients who are stable and virologically suppressed. The paper aims to assess adherence to antiretroviral therapy (ART) and viral load suppression (VLS) among adolescents and young adults enrolled to multi-month dispensing (MMD) for ART prescriptions.

Methods: This was retrospective cross-sectional analysis of routinely collected data from care and treatment clinics for adolescents and young adults living with HIV and initiated on antiretroviral therapy (ART), between 2016 to 2020 in 26 Tanzanian Regions. Descriptive statistics were used to summarize the covariates of study sample. Logistic regression was used to determine adjusted odds ratios (AOR) for the effect of MMD on VLS comparing 3-month dispensing (3MD) and 6-month dispensing (6MD) with the standard, one-month dispensing.

Results: In 20676 stable clients on ART, 10373 (50.2%) were initiated on 3MD, 6951 (33.6%) on 6MD, and 3352 (16.2%) remained on one month standard of care (SOC). Those that received 3MMD had better adherence to ART (AOR=1.63,

$p < 0.001$) and greater VLS (AOR=3.88, $P < 0.001$) than SOC. However, those that received 6MMD also had better adherence to ART (AOR=1.42, $p = 0.001$) and higher VLS (AOR=1.65, $p < 0.001$) than SOC. Conclusions: A large proportion of eligible clients were initiated on multi-month dispensing in either three- or six-month prescriptions with reduced clinical visits and extended ART refills. The study also validates that the shift to multi-month prescription schedules and provides evidence of better adherence to ART and viral load suppression.

A joinpoint regression analysis of trends in HIV incidence in Brazil over 20 years

Denise Souza¹, Cleber Carmo¹, James Welch¹

¹Oswaldo Cruz Foundation (Fiocruz), Brazil

Introduction/Objectives: The HIV/AIDS epidemic, involving infection by the etiological agent Human Immunodeficiency Virus (HIV) or illness by Acquired Immunodeficiency Syndrome (AIDS), began in the early 1980s and involves diverse dynamics. This study aimed to describe the temporal evolution of ratios of HIV infections e AIDS cases in Brazil and in each of the country's states between 2000 and 2019 among subjects of both sexes 13 years and older using the joinpoint regression method. **Methods:** This ecological study analyzed temporal series of standardized incidence of HIV/AIDS stratified by sex. Incidence data was accessed from the Brazilian National Disease Notification System (SINAN) from the Brazilian Health Ministry. Population data was accessed from the Brazilian Institute of Geography and Statistics (IBGE). Trend analyses were produced by joinpoint regression models and obtained by annual percent change (APC) and average annual percent change (AAPC).

Results: During the study period, there were 773.893 notified cases in Brazil. Trend analysis by state indicated rising incidence for both sexes (AAPC > 0) in the country's North and Northeast regions and a decline trend (AAPC < 0) in the South and Southeast regions. There was a general trend of decline in incidence among male population (AAPC = -0,6; CI95% - 0,1; 0) and rise among female population (AAPC = 1,4; CI95% 0,8; 1,9). **Conclusions:** Higher incidence was observed among male population. Analysis by state indicated distinct trends in different regions of Brazil. These disparate trends suggest a national scenario of social inequality.

Patients presenting to a united states academic health center emergency department following opioid overdose show elevated rates of Hepatitis C and limited testing history

John Swift¹

¹Institute for Collective Health, University of Missouri School of Medicine, United States

Background and Objective: Cases of acute Hepatitis C Virus (HCV) increased approximately 3.8-fold between 2010 and 2017 due, in part, to increasing injection drug use and surveillance. Furthermore, multiple HIV outbreaks in Europe and North America have been attributed to injection drug use. Emergency departments are uniquely situated to address infections among people using opioids given their limited utilization of other healthcare resources. This review assesses prevalence, testing history, and potential benefit for screening of HIV and HCV among patients presenting to emergency departments following an opioid overdose.

Methods: 134 emergency department encounters at an academic medical center in the central United States representing 120 unique patients diagnosed with poisoning by opioids between January 2021 and May 2022 were included in the analysis. Emergency department and most recent primary care visit notes, as well as laboratory results from January 2000 to May 2022 were reviewed for history of HIV and HCV testing and viral load.

Results: 48 patients (40%) had a history of HCV testing and 54 (45%) had a history of HIV testing. 20 patients had tested positive for HCV (41.6% of tested, 16.7% of total), and 1 had tested positive for HIV (1.9% of tested, 0.8% of total). 8 patients had detectable HCV viral loads, 6 were virologically suppressed, and 6 had no documented quantitative testing. 1 patient had a detectable HIV viral load.

Conclusions: There is a substantial burden of HCV among individuals presenting to American emergency departments following opioid overdoses. Universal HCV screening for individuals being observed following an overdose could detect many undiagnosed HCV infections. These results have been reported to the state government which plans to implement a program to test all emergency department patients suspected of opioid abuse for HCV and to coordinate treatment for those who test positive.

Anti-HCV testing acceptance and seroconversion rates among people who use drugs and are under opiate substitution treatment (Hippocrates Epidemic Detection System)

Olga Anagnostou¹, Katerina Micha², George Tsitsanis¹, Argyro Karakosta³, Georgia Papadopoulou², Eleni Panopoulou², Christos Danopoulos², Charikleia Tsatsaroni², Nikolaos Avgerinos²

¹Greek Organization against Drugs (OKANA), Greece, ²Greek Organization Against Drugs (OKANA), Greece, ³Department of Hygiene and Epidemiology, Athens Medical School, University of Athens, Greece

Background and Objective: People who use drugs (PWUD) are at high-risk for hepatitis C virus (HCV) infection. Opiate substitution treatment (OST) reduces the risk of infection. Testing opportunity acceptance and seroconversion rates among PWUD under OST are of great importance for public health. **Methods:** AntiHCV rapid test was offered free of charge to all individuals under OST in Athens (N=2,892) from Sep2021 to Oct2022. A retrospective analysis of data collected was conducted. In total, 83.3% were male, mean (SD) age 51(9) years, 56.3% buprenorphine/43.7% methadone, in OST public units of large(>200patients:35.3%), medium (100-199patients:31.5%) or small capacity (<99 patients:33.2%).

Results: From 2,892 participants 2040(70.5%) have a previous positive test and were not retested. AntiHCV test was performed to 540 out of 852 eligible persons (63.4%); Of the 312 not tested, 42(13.5%) refused screening, 8(2.6%) were temporarily out of OST and 262/312(84%) did not present for testing due to unknown reasons. Tested individuals didn't differ significantly with those who refused testing with respect to gender, age and opiate substitution substance. Refusal rate was slightly higher in medium-capacity units (19.9%) vs smaller (14.9%) and larger (13%) ones, however the differences were not statistically significant. No significant differences were observed among patients who refused testing and the rest not screened. In total 103/540(19.1%) were found AntiHCV(+). Seroconversion, defined as a positive rapid test in a known antiHCV (-) individual, was documented in 98/540(18,1%) and it was higher in large-capacity (24.3%) compared to medium-capacity units (6.9%) ($p < 0.001$). Seroconversion rate was higher in methadone participants (21.3%) vs buprenorphine (15.4%), although the difference was not statistically significant. Rates didn't differ significantly by sex and age. **Conclusions:** High rates of antiHCV seroconversion are documented among PWUD even when under OST. Further study on high-risk behaviors while under substitution is needed. Testing acceptance by PWUD is a challenge even when test is offered free of charge in a treatment setting.

Epidemiological Burden of Hepatitis B Infection among Military Personnel in Khartoum State

Adam Ahmed¹

¹Sudan

Background and Objectives: Viral hepatitis has been identified as the seventh leading cause of mortality worldwide. In 2015 an estimated 1.34 million deaths in the world is due to viral hepatitis, approximately half (47%) are related to hepatitis B virus (HBV). The WHO classified Sudan among the highest-burden countries for hepatitis B virus infection (>8%). Living in military camps and being at a greater risk for injury and hospitalization results in a higher risk of HBV infection acquisition among military personnel. Sudan has launched the first national strategic plan on viral hepatitis from 2019 – 2025. The aim of this study is to assess the epidemiological burden of HBV infection among military personnel to help in the implementation of the national strategic plan.

Methods: A sample of 770 military personnel was selected by stratified cluster sampling. Seroepidemiologic and questionnaire survey tools have been used to collect the data, and SPSS was used for analysis.

Results: A seroepidemiologic survey was conducted among 770 active military personnel working in four areas in Khartoum State. More of them are male (91%), and only (9%) are female. The majority age group is 18 -30 years (46.5%), and (34.8%) of the group is 31 – 45 years. The seroprevalence HBsAg among military personnel was 8.9%. The study indicated an association between the age 31-45 years and HBV infection $P > 0.05$, and between the deployment duration and HBV infection $P > 0.05$. The study showed a low awareness about the disease (35%), mode of transmission (43%), and taking treatment (23%).

Conclusions: HBV infection among military personnel was high and the main risk factors the age, education, and longer deployment duration. Poor disease awareness and delays in treatment increase the disease burden. Screening surveys, treatment with regular follow-up visits, health education, and vaccination program are needed for disease control.

Stigma, self-efficacy and susceptibility associated with knowledge about hiv in high school students

Carolina Pérez¹, Carlos Montero², Josue Villegas-Dominguez², Iant Reyes², Maria Rascon²

¹School of Medicine, Universidad Veracruzana, Mexico, ²Universidad Veracruzana, Mexico

Background: The state of Veracruz, Mexico for 36 years has occupied the first places in new and prevalent cases of patients with HIV and AIDS, occupying during the year 2019 8.7% of the total cases of AIDS nationwide and 12.39% of the total Seropositive cases registered, being important the treatment for these patients to avoid their discrimination since it can be a risk factor for anxiety, depression or suicidal ideation. **Objective:** To determinate the association between the level of knowledge and attitudes for HIV / AIDS. **Methods:** A cross-sectional, prospective, analytical and observational study was carried out. High school students from the city of Veracruz-Boca del Río, Mexico were included during the period January - March 2021, students who refused to participate were excluded. The sampling was not probabilistic for temporality and convenience. The knowledge about HIV, stigma, self-efficacy and susceptibility to HIV, was quantified with the HIV / AIDS-65 scale with scores of 0 to 100 likert type. The surveys were conducted through Google Forms® and were by an internet device. For the data analysis the SPSS v22 software, were used, with statistical significance $p < 0.05$.

Results: 895 students were included; The correlation between level of correct knowledge and positive attitude, negative attitude, neutral attitude, susceptibility and self-efficacy was less than 0.35 in all cases. Higher quartiles were determined in knowledge scores and the attitude, presenting an OR of 2.3 (95% CI 1.6-3.2) for high self-efficacy, OR 3.1 (95% CI 1.7-5.4) for susceptibility, OR 1.6 (95% CI 1.0 - 2.7) for neutral attitude and OR 2.4 (1.6-3.4) for positive attitude ($p < 0.05$), while the negative attitude resulted with $p > 0.05$. **Conclusions:** knowledge has a low correlation with attitude, susceptibility and self-efficacy, and high knowledge is associated with a better attitude, susceptibility and self-efficacy for HIV / AIDS.

DOI: 10.18332/popmed/165505

Level of knowledge of HIV / AIDS associated with risk behaviors and use of Prep / Pep in students

Carolina Pérez¹, Carolina Taffoya², Josue Villegas-Dominguez², Iant Reyes¹

¹School of Medicine, Universidad Veracruzana, Mexico, ²Universidad Veracruzana, Mexico

Background: In Mexico, the state of Veracruz occupied the second national place in the number of HIV / AIDS cases during 2019. The total cases registered in Veracruz, 5.8% were in young people between 15 and 19 years old. **Objective:** To determinate the association between the level of knowledge about HIV / AIDS and risk behaviors in high school students. **Methods:** A cross-sectional, prospective, analytical and observational study was carried out. High school students from the city of Veracruz-Boca del Río, Mexico with active sex life were included, students who refused to participate were excluded. The WHO Behavior Assessment Test and the HIV / AIDS-65 were applied. The surveys were conducted through Google Forms® and were answered on that same platform in an electronic device with internet. For the data analysis the SPSS v22 software.

Results: 895 students were interviewed, of which 363(40.55%) had active sex life and 3(0.8%) reported being HIV positive. Sexual orientation, having sexual activity under the consumption of illicit substances, being monogamous or promiscuous, initiate sexual life early, the frequency in the use of condoms, accepting to take Prep or Pep in case of having risk relationships had no association with the high level of knowledge about HIV ($p > 0.05$). Use condoms in the first sexual relationship (OR 1.8, 95%CI 1.94-3.2), susceptibility (OR 3.1 95% CI 1.6-6.8), negative attitude (OR 0.04, 95%CI 0.01-0.1), autonomy (OR 2.5, 95%CI 1.5-4.0) and positive attitude (OR 2.3, 95% CI 1.4-3.9) with p value < 0.05 . **Conclusions:** the high level of knowledge in students with active sexual life is only associated with the use of condoms during the first sexual intercourse, without presenting differences to modify other risk behaviors or the intention of taking Prep or Pep in case of anticipating the need of using it.

Characterising a syndemic among women impacted by syphilis and the toxic drug supply in Fraser Health Authority, Canada using latent class analysis

Vivian Ngo¹, Jannie Leung², Maulik Baxi³, Troy Grennan⁴, Adrianna Paiaro⁵, Vanessa Ryan⁴, Jason Wong⁶

¹Faculty of Medicine, University of British Columbia, Canada, ²Fraser Health Authority, Canada, ³Fraser Health Authority, University of British Columbia,

Canada, ⁴British Columbia Centre for Disease Control, Canada, ⁵University of British Columbia Faculty of Medicine, Canada, ⁶British Columbia Centre for Disease Control, University of British Columbia, Canada

Background and Objectives: A syphilis outbreak and overdose/toxic drug poisoning (TDP) emergency have been declared in the province of British Columbia (BC), Canada. In Fraser Health Authority (FHA), BC's largest regional health authority, rates of infectious syphilis and TDP events have increased among women since the start of the COVID-19 pandemic. We aim to understand social and structural factors associated with the emergent syndemic of women affected by infectious syphilis and TDP to inform targeted interventions and improve service provision. **Methods:** The data source was a retrospective chart review of all women-identified individuals diagnosed with infectious syphilis in FHA from January 2021 to April 2022 from hospital records and public health databases. We used Latent Class Analysis (LCA) to identify subgroups based on patterns of socio-demographic factors (e.g. unstable housing), comorbidities (e.g. mental health disorders), and health service utilisation.

Results: A total of 113 women were included, of whom 61% were ever diagnosed with an opioid- or stimulant use disorder and 30% had an emergency department visit for TDP. We identified three subgroups by LCA: 1. "Incarceration experience, comorbidities" ($n=22$, 19%): incarceration (100%), mental health disorder diagnosis (96%), stimulant use (86%), income assistance (59%), 2. "Multiple barriers, child removal" ($n=37$, 33%): concurrent opioid and stimulant use (78%), child removal (55%), intimate partner violence (46%), 3. "Greater resiliency factors" ($n=54$, 48%): attached to primary care practitioner (57%), syphilis diagnosed during pregnancy (19%).

Conclusions: Two subgroups (52% of the sample) were highly impacted by mental health, substance use challenges and structural vulnerabilities, which may results from social and systemic inequities driving the syndemic. Enhancing women-centred health services addressing sexual health, mental health and determinants of health may increase opportunities for engagement, prevention and harm reduction. An additional subgroup (48%) had fewer structural vulnerabilities, and further analyses are needed to better elucidate their distinct care needs.

Implementation of the explicit health guarantees program for the human immunodeficiency virus and its intervention in mortality in Chile

Christopher Sánchez-Moya¹

¹Universidad Mayor, Chile

Background and Objectives: In 2004, Law 19966 in Chile, was enacted to establish the Explicit Health Guarantees (GES). This public policy was designed to facilitate access, coverage, and quality of health care for the population by guaranteeing all beneficiaries minimum benefits, timely, quality care and care protocols for a group of priority diseases due to their prevalence and mortality, including acquired immunodeficiency virus (HIV)/AIDS, intervening in prevalent mortality rates in the country.

Objective: To describe the influence of the HIV/AIDS GES public policy on mortality rates in Chile. **Methods:** A quantitative, cross-sectional, and descriptive design was conducted, using interrupted time series, Newey-West estimator, 95% confidence. **Sample:** HIV deaths between 2000 and 2020 registered in the Chilean Statistical Office.

Results: The median number of HIV deaths due to other infectious diseases was 241 person/year in the early 2000s. The average number of deaths associated with pregnancy complications was 3 person/year between 2000 and 2010. Deaths due to other specified diseases, have a maximum of 109 person/year in 2015, and a minimum of 22 person-years in 2020. After the implementation of the program, there is an average decrease of 41 deaths/year. The access of public sector patients to the program is 100% in Chiles hospital network and first preventive care, starting in 2013.

Conclusions: There was evidence of a reduction in mortality from HIV and related diseases between 2013 and 2020. The eradication of HIV deaths in pregnancy is total until 2020. A significant decrease in mortality was observed after the adjustment of the program in 2016 related to promotion and prevention actions. The impact of the intervention was measured through mortality, which does not include other relevant variables in the disease-death process, such as bio sociodemographic, socioeconomic, and geographic factors.

Factors associated with intention to use self-sample collection for HIV and other sexually transmitted and blood-borne infections

among men who have sex with men in British Columbia, Canada

Ihoghosa Iyamu^{1,2}, Mark Gilbert^{1,2}, Aidan Ablona¹, Ben Klassen³, Heather Pedersen¹, Devon Haag¹, Hsiu-Ju Chang¹, Nathan Lachowsky⁴

¹British Columbia Centre for Disease Control, Canada, ²School of Population and Public Health (SPPH), University of British Columbia (UBC), Canada, ³Community-Based Research Centre, Canada, ⁴Community-Based Research Centre, School of Public Health and Social Policy, University of Victoria, Canada

Background: Population subgroups likely to use self-sample collection for HIV and other sexually transmitted and blood-borne infections (STBBIs) are not well-characterized in Canada. Given provincially organized health services, we assessed factors associated with intention to use self-sample collection among gay, bisexual, and other men who have sex with men (GBMSM) in British Columbia. **Methods:** We analysed data from the 2019 Sex Now online survey of GBMSM aged ≥ 15 years in Canada. Respondents indicated how likely they would use a testing service by ordering a self-collection kit online, having it mailed to specified addresses and shipped to a lab for testing. We assessed associations between intention to use self-sample collection (i.e., likely/very likely vs. other responses) and explanatory variables including sociodemographic characteristics, sexual behaviors, healthcare access and testing. Using multivariable logistic regression, we selected our model using automated backward elimination based on Akaike information criterion, after retaining predictors identified in the literature.

Results: Overall, 758 respondents had complete responses to our survey questions, with a mean age of 39.39 years (SD: 14.25). Among these, 66.1% (501) indicated intention to use self-sample collection. In multivariable analysis, age ≥ 30 years (adjusted odds ratio [AOR] 1.64, 95% CI 1.11-2.42), having last STBBI test between 4-6 months prior to the survey (AOR 1.82, 95% CI 1.11-3.05), and experiencing delayed testing due to access barriers (e.g., cost, distance, inconvenient hours, fear of judgement etc.) (AOR 2.53, 95% CI 1.77-3.65) were associated with higher odds, while participants with a bachelor's degree had lower odds of intending to use self-sample collection (AOR 0.46, 95% CI 0.248-0.74) (Figure 1).

Conclusions: The high intention to use self-sample collection for HIV and other STBBIs suggests that the service can potentially increase access to testing services for GBMSM in BC, especially for those experiencing delayed testing due to health service access barriers.

Stigma towards tuberculosis in nurses from high complexity care centers in Cartagena, Colombia

Irma Castillo Avila¹, Zuleima Cogollo Milanes², Andres Beltrán Arteaga³

¹Universidad de Cartagena, Colombia Universidad de Cartagena Campus de salud. Cartagena Colombia Colombia, ²Universidad de Cartagena, Colombia Colombia, ³Universidad de Cartagena, Colombia Australia

Background: People with tuberculosis experience rejection in many contexts. Recognizing the stigma in health professionals under your care can help reduce this negative situation.

Objective: To determine the stigmatization level of the nursing staff towards the tuberculosis patient, in highly complex health institutions.

Method: A descriptive study was performed for twelve months with a population and sample of 149 nursing professionals who work in highly complex health institutions in cartagena. A questionnaire was applied to measure sociodemographic characteristics and a scale to measure attitudes towards tuberculosis, which consists of 25 items and closed yes and no questions; the greater the number of positive responses, the higher the level of stigmatization. The collected information was tabulated and processed in the microsoft excel program. Descriptive statistics were applied to the data and the results were presented in tables and graphs.

Results: Of the 149 participants, the majority are women (91.9% (137)), stratum 2 (47.7% (71)), single (45.0% (67)), and only with undergraduate studies (59.7% (89)). 63.1% (94) of nursing professionals think that people with tuberculosis experience greater economic difficulties than those who do not suffer from this disease, 65.1% (97) affirm that it is risky to eat or drink with a nursing friend with tuberculosis. Likewise, 8.1% (12) think that people sick with tuberculosis can spread the disease by shaking hands or hugging and 93.3% (139) believe that people feel uncomfortable being around someone who is sick with tuberculosis. **Conclusion:** Nursing professionals stigmatize tuberculosis patients in a high degree. Women, those who only have an undergraduate degree, those from lower strata and those who work in administrative areas have a higher level of stigmatization; all these may become a barrier to the provision of quality nursing care to the patient.

Epidemioclinical profile of cutaneous leishmaniasis in tataouine: a prospective longitudinal study

Ines Cherif¹, Jihène Bettaieb¹, Ghassen Kharroubi¹, Wissem Ghawar¹, Mohamed Snoussi¹, Sadok Salem¹, Amor Bouaoun², Said Chouchen², Afif Ben Salah³

¹Laboratory of Medical Epidemiology, Institut Pasteur de Tunis, Tunisia,

²Regional Health Directorate of Tataouine Tunisia, ³Arabian Gulf University, Road 2904 Building 293 Manama Bahrain

Background: Cutaneous leishmaniasis (CL) constitutes a real public health problem in Tunisia mainly due to its consequences in terms of quality of life. The identification of the clinical and epidemiological characteristics of the different forms of CL will facilitate the differentiation between them and will be useful for the therapeutic management, the prognostic evaluation and the adjustment of control measures. The aim of this study was to identify the different forms of CL in the city of Ghomrassen in Southern Tunisia according to parasite species and to describe the epidemiological and clinical profile of each form.

Methods: A prospective descriptive study was conducted between 07/02/2018 and 12/06/2020 at Ghomrassen primary healthcare facility in Tataouine. Adult volunteers between 18 and 65 years of age with CL were included in this study. Each participant was followed until lesions were healed with a maximum follow-up time of one year from the date of the first visit. Species were identified using the PCR-RFLP (Polymerase chain reaction- Restriction fragment length polymorphism).

Results: A total of 262 patients were included. Parasite species were identified in 64.1% of participants, of whom 83.9% were infected by *L. major*. *L. major* lesions occurred mainly in autumn (54.6%), were mostly multiple (58.2%) and situated on limbs (94.3%). On the other hand, *L. tropica* lesions occurred mainly in winter (44.4%, $p=0.02$) and were mostly single (63.0%, $p=0.05$). The duration of lesion evolution was comparable between *L. major* and *L. tropica* (151 days \pm 4.5 vs 148 \pm 3.8, $p=0.9$).

Conclusions: The coexistence of two species of leishmaniasis in the same geographical area argues for the promotion of species identification by encouraging the development of sensitive, specific, and easy-to-use tests that can be used in primary health care facilities in endemic rural regions.

Fine mapping of ascaris lumbricoides, trichuris trichiura and hookworm infections in sub-districts of makenene in Centre Region of Cameroon

Cyrille Kamdem Nguemngang¹, Auvaker Tiofack Zebaze¹, Estelle Mewamba Mezajou¹, Edmond Tekeu Mengoue¹, Pythagore Fogue Soubgwi¹, Esthellène Tchounkeu Yangea¹, Joël Atiokeng Tatang², Carole Tchami Mbagnia³, Hilaire Womni⁴, Gustave Simo¹

¹University of Dschang, Molecular Parasitology and Entomology Unit, Department of Biochemistry, Faculty of Science, University of Dschang, PO Box 67, Dschang, Cameroon, ²University of Dschang, Research Unit of Biology and Applied Ecology, Department of Animal Biology, Faculty of Science, University of Dschang, Dschang, Cameroon, ³University of Yaounde, Parasitology and Ecology Laboratory, Department of Animal Biology and Physiology, Faculty of Science, University of Yaoundé I, Yaoundé, Cameroon, ⁴University of Dschang "Unité de Recherche de Biochimie, des plantes Médicinales, des Sciences Alimentaires et Nutrition", University of Dschang, Dschang, Cameroon

Background and Objective: Preventive chemotherapy (PC) that remains the main control strategy recommended by the World Health Organization to achieve the elimination of soil-transmitted helminth (STH) infections as a public health problem must be strengthened by identifying the remaining transmission hot-spots for the deployment of appropriate control measures. This study was designed to perform micro scale mapping in order to identify transmission hot-spots of STH infections for targeted control operations.

Methods: Stool samples were collected from 1775 children in ten primary schools of eight sub-districts of Makenene in Cameroon. Kato-Katz technique was used to process and examine stool samples to detect STHs eggs. The prevalence of STH species as well as the infection intensities was compared. Data visualizations in forms of maps were made using Quantum geographic information system (QGIS) software.

Results: The overall prevalence of STH infections was 4.8% with a 95% confidence interval (CI) of 3.8-5.9%: 3.0% (95% CI 2.2-3.9) for *Ascaris lumbricoides*, 1.4% (95% CI 0.9-2.0) for *Trichuris trichiura* and 0.8% (95% CI 0.5-1.4) for hookworms. The prevalence of STH species differ significantly between schools and sub-districts.

The intensity of infections was light (2.4%, 1.1% and 0.8%), moderate (0.4%, 0.1% and 0.1%) and heavy (0.2%, 0.2% and 0%) for *A. lumbricoides*, *T. trichiura* and hookworm respectively. Between schools and sub-districts, significant difference was recorded in the means of infection intensities of *T. Trichiura* and hookworms. This difference was also significant for *T. Trichiura* when comparison were between sex. Fine mapping revealed that children harbouring heavy infections were clustered in the same sub-districts.

Conclusion: This study showed a diversity in the prevalence of STH species. It also highlighted the need for micro scale mapping to enable the localisation of high endemicity sub-districts where targeted control operations must be deployed to achieve STH elimination.

The impact of the disruption of the seasonal chemoprevention services on the malaria epidemic in senegalese children: a study in the Sédhiou and Kolda regions

Giorgia Alderotti¹, Vieri Lastrucci¹, Carlotta Carboni², Lorenzo Stacchini³, Primo Buscemi³, Amadou Camara⁴, Mansour Faye⁴, Omar Sagna⁵, Adama Faye⁶, Ibrahima Seck⁶, Maria Caldes²

¹Epidemiology Unit, Meyer Children's Hospital, Florence, Italy, ²Global Health Center, Meyer Children's University Hospital Italy, ³Medical Specialization School of Hygiene and Preventive Medicine, University of Florence, Italy, ⁴Medical Region of Sédhiou, Senegal, ⁵President Malaria's Initiative, USAID, Senegal, ⁶Cheikh Anta Diop University of Dakar, Senegal

Background and Objective: In Senegal seasonal chemoprevention (SMC) is routinely provided to children aged between 3-120 months. During the epidemic season 2018-2019 healthcare workers declared a strike that totally disrupted the SMC services in the regions of Sédhiou and Kolda. The study aimed to investigate the impact of the strike on the malaria epidemic dynamic.

Methods: Three epidemic seasons (from May to April) were considered, namely pre-strike, strike and post-strike seasons. For each season, monthly numbers of malaria cases occurred in children aged between 3-120 months and 10-day average rainfall data were retrieved from the regional databases. Incidence rates were calculated at regional and district levels and regression analyses using interrupted time series models were performed to evaluate differences in the incidence of malaria among the considered seasons.

Results: In the strike seasons, only 20 (16%) health centers (out of 124) provided SMC services. During the strike season, a total of 30,522 and 28,129 malaria cases were registered during the pre- and post-strike seasons, respectively, while in the strike season a total of 57,543 cases were observed. The malaria incidence in the strike season was about two times higher than the one registered in the pre-strike season (incidence rate ratio: 1.89, 95% CI 1.56-2.28; $p < 0.001$), this significant increase was observed at regional and sub-district levels. Cumulative seasonal average rainfall was lower in the strike season (Kolda: 906.16 mm, Sédhiou: 971.93 mm) compared to the pre-strike season (Kolda: 978.80 mm, Sédhiou: 1051.66 mm), similar findings were observed at district level.

Conclusion: Our findings showed that the interruption of the SMC is associated with a significant increase of malaria incidence in children without any significant increase in precipitation. Our findings confirm that SMC is essential to reduce the burden of malaria in children residing in areas of highly seasonal transmission.

Tb notification in children; the experience of targeted community demand creation amidst insecurity in imo state Nigeria.

Arinze Ajogwu¹, Adaeze Ikeru², Jude Ilozumba¹, Charles Okafor³

¹Caritas Nigeria Caritas Nigeria Abuja, Nigeria Nigeria, ²Caritas Nigeria, ³Imo State TB and Leprosy Control Program Imo State TB and Leprosy Control Program Imo State Nigeria Nigeria

Background and Objective: The 2022 Global TB report shows that Nigeria is one of the 30 high-burden countries that have significantly contributed to the global Childhood TB epidemic. Despite significant improvements being made by the country in TB case notifications, children are being left behind as the childhood proportion remained at 7% nationally. The current security challenges in some parts of the country including the Imo state, worsen this challenge. This study aimed to determine how targeted community demand creation can contribute to TB Notification in Children in security-challenged settings.

Methods: The hotspot identification approach was used to identify and cluster community entities; such as hospitals, patent medicine vendors, and traditional birth attendants. These centers were engaged to refer children to TB diagnosis and treatment services, over a 21-month period, (January 2021 to October 2022).

The inclusion criteria considered in identifying the hot spots included proximity to living areas, schools (targeting preschool and early school-aged children), Orphanages, and childrens clinics. Targeted demand-creation activities were carried out in these clusters.

Results: On the whole, 1,104 centers were engaged, and 162 demand-creation activities were conducted leading to the referral of 579 children. A total of 115 pediatric TB cases were placed on treatment through this intervention. The Paediatric TB notification trend within this period showed a continuous increase in childhood TB cases started on treatment.

Conclusion: Targeted outreaches through hotspots or clusters help to reduce the security challenges posed by large crowds gathering in the communities and patients traveling long distances to access treatment. This approach is effective in ensuring pediatric TB cases are identified and started on treatment amidst the worsening security challenges in many parts of Nigeria like Imo State.

Knowledge, attitude, and perception of monkeypox among medical/health students across media space in Nigeria

Stephen Ugwu¹, Bartholomew Okolo², Stephen Ugwu¹, Sodiq Abolade³, Augustine Ofeh¹, Temitope Awoyinka¹, Eunice Ayeni¹, Kolawole Eniola¹

¹Infectious Disease Research Group Nigeria, ²Infectious Disease Research Group, Nigeria, ³Infectious Disease Research Group

Background: Monkeypox is a rare disease caused by infection with the Monkeypox virus (MPXV). Although monkeypox existed and declined in the past, its re-emergence is simultaneous with the rise in cases recently.

Methods: This study utilized a non-interventional, anonymous, self-administered web-based survey through a descriptive cross-sectional design to collect data from medical/health students (undergraduate, graduate, and postgraduate students). The E-questionnaire was administered from 22nd July to 5th August through social media, and the data collected and extracted through an excel spreadsheet was analyzed using IBM SPSS Statistics 26.0.

Results: A total of 203 respondents were obtained from 22nd July to 5th August, out of which 109 (53.7%) were females, 92 (45.3%) were males with 18-25 years (63.5%), 25-30 years (26.6%), <30 years (7.4%) and <18 years (2.5%) age groups. Of the total respondents, 94.1% have heard about monkeypox before, 59.1% believed that monkeypox could be managed, 80.8% believed that monkeypox is zoonotic but can be transferred from human to human, and the majority (60.1%) are aware of the symptoms of monkeypox.

Conclusions: Medical/health students across social media show a relatively high knowledge of the Monkeypox virus with significant knowledge gap regarding the evolving epidemiologic and clinical manifestations, and the variety of components implicated in monkeypox transmission. Nonetheless, the knowledge is to be sustained and reinforced through continued awareness on social media and in rural areas with a high percentage of basic internet coverage and literacy. In order to direct proper surveillance, data collecting, readiness, and response operations, public health/surveillance capacities in Nigeria must be urgently developed.

Effect of treatment on school-aged children's hemoglobin levels in a Schistosoma mansoni endemic area of Minas Gerais, Brazil.

Gisele de Andrade¹, Leonardo Matoso¹, Alexandre Lisboa¹, Rodrigo Correa-Oliveira², Andrea Gazzinelli¹

¹Participant Nursing school - Universidade Federal de Minas Gerais Brazil,

²Participant Fundação Oswaldo Cruz - FIOCRUZ Brazil

Background and Objective: Schistosomiasis is an important public health problem in Brazil and still represents a significant segment of the global burden of illness. The objective of this study was to assess the association between schistosomiasis and soil-transmitted helminths (STH) infection and hemoglobin levels of school aged children residing in areas in the Jequitinhonha Valley, Minas Gerais, Brazil.

Methods: A cohort of 387 school-aged children positive for *Schistosoma mansoni* eggs were included. Parasitological, socioeconomic, demographic, and hemoglobin were analyzed in all children infected or coinfecting with *S. mansoni*, hookworm, and/or *Ascaris lumbricoides*, aged 6 to 15 years, in eight endemic areas. Individuals were treated until they were determined to be negative for the presence of *S. mansoni* or STH. Individuals were surveyed again 12 and 24 months from the date of successful treatment. Hemoglobin levels before and after treatment were analyzed by multifactorial analysis of variance, with the predictors reinfection group, (co-)infection, time of observation, age, and the interaction between them. To evaluate the effect of antiparasitic treatment on hemoglobin levels, values before and after treatments were analyzed by Student's paired t

test. Repeated measures ANOVA was used to assess the association between hemoglobin levels with different participant characteristics.

Results: the mean levels of hemoglobin in the first (13.1 g/dL) and second (13.3 g/dL) year post-treatment were significantly higher than at baseline (12.8 g/dL). At baseline, the hemoglobin levels of the co-infected individuals were significantly lower in relation to the non-co-infected individuals. However, in reinfected and non-reinfected groups this association was not statistically different in any follow up time point. Longitudinal analysis of hemoglobin level showed an increase over time, independent of age and reinfection by *S. mansoni*.

Conclusion: The data suggest that treatment elevated Hb levels in this population, especially in the group of *S. mansoni*-infected children co-infected with STH.

Rsv epidemiological burden in paediatric outpatients in Italy: a systematic review

Sara Boccalini¹, Benedetta Bonito¹, Cristina Salvati¹, Enrica Stancanelli¹, Mario Bruschi¹, Giulia Ionita¹, Johanna Iamarino¹, Davide Bentivegna¹, Primo Buscemi¹, Giulia Ciardi¹, Claudia Cosma¹, Lorenzo Stacchini¹, Cristiana Conticello¹, Manjola Bega¹, Annamaria Schirripa¹, Marco Del Riccio¹, Lorenzo Bertizzolo², Salvatore Parisi², Francesca Trippi², Paolo Bonanni¹, Angela Bechini¹

¹University of Florence Department of Health Sciences Viale G.B. Morgagni, 48 Italy, ²Sanofi 14 Espa. Henry Vallée, 69007 Lyon France

Background: Respiratory Syncytial Virus (RSV) infection is a paediatric threat, being the main cause of lower respiratory tract infections (LRTIs) in children <5 years of age and often leading to severe consequences (i.e., bronchiolitis and pneumonia). Preventive strategies are and will be available to reduce the burden of this respiratory infection. Therefore, in order to assess the effect of prevention strategies, establishing a baseline before implementation may be considered to be relevant. The aim of this systematic review is to describe the epidemiological burden of RSV infection in paediatric outpatients aged 0-5 years in Italy. Methods: We performed a systematic review by consulting PubMed, Embase, Scopus and the International HTA Database. We then applied inclusion and exclusion criteria, including limiting to English and Italian languages and articles published between Jan 1st 2000 and July 14th, 2022, requirement of RSV test-positive data and from patients in the aforementioned age range. Results: We retrieved 20,845 records collectively, from which 9 articles were eligible for our study. Overall, we found RSV test-positivity in outpatient children ranged from 18% to 41%. Data comparison across studies was challenging because of differences in initial diagnosis, source of information, sample population, and study design. Importantly, the RSV positivity increased from 2001-2002 (23.8%) to 2019-2020 (40.8%): this is perhaps due to true changes in the epidemiological trends, detection bias due to increased awareness of RSV by the medical professionals and the availability of more sensitive diagnostic techniques. Conclusions: To our knowledge, this is the first review summarizing RSV epidemiology in paediatric outpatients in Italy. In the future, more data on this topic will be crucial for an appropriate and effective prevention strategy to manage the RSV-related disease burden in paediatric outpatients.

Funding: unrestricted grant by Sanofi.

Neuroinvasive toscana virus, Italy, 2016-2021: should we invest in improving surveillance?

Flavio Mellace¹, Flavia Riccardo², Martina Del Manso², Daniele Petrone³, Emmanouil Fotakis³, Flavio Mellace¹, Emmanouil Fotakis⁴, Daniele Petrone³, Antonino Bella⁴, Maria Caporali³, Gioia Bongiorno³, Ilaria Bernardini³, Marco Di Luca³, Giulietta Venturi³, Claudia Fortuna³, Stefania Giannitelli³, Federica Ferraro⁵, Francesco Maraglino⁵, Patrizio Pezzotti³, Flavia Riccardo³

¹Department of Medicine (DAME), University of Udine - Udine; Italian National Institute of Health (ISS), Department of Infectious Diseases - Rome Italy, ²Department of Infectious Diseases, Italian National Institute of Health (ISS), Rome, Italy, ³Italian National Institute of Health (ISS) - Rome Department of Infectious Diseases Italy, ⁴Italian National Institute of Health (ISS) - Rome, ⁵Italian Ministry of Health - Rome Department of Prevention, Infectious Disease Office Italy

Background and objective: Among viruses of the Phlebovirus genus in the Mediterranean area, sand flies transmitted Toscana virus (TOSV) can cause human neuro-invasive disease. Due to a lack of international surveillance, its impact on human health is poorly known, and considering high phlebotomine vectors density detected in some disease foci. We aim to describe the epidemiology all cases of

neuro-invasive TOSV notified in Italy from 2016 to 2021.

Methods: We analysed data from the Italian national TOSV surveillance system on all notified cases of neuro-invasive disease laboratory-confirmed with at least one of the following: TOSV isolation, TOSV-IgM in cerebrospinal fluid (CSF); TOSV RT-PCR on CSF/blood/urine/other; TOSV IgM and IgG in serum; seroconversion/four-fold increase in TOSV antibody titre.

Results: Between July 2016 and October 2021, 6 transmission seasons, 331 confirmed cases of neuro-invasive TOSV were reported in Italy (median 56 cases/year, range 35 in 2016 - 85 in 2018). Most cases were confirmed by PCR (271, 82%) and/or TOSV IgM and IgG detection (235, 71%).

Cases were reported in 9/21 Italian Regions, mainly in the north-east. Average age was 46 (range 0 - 89 years), most cases were male (233, 70%). Disease onset occurred mainly between July and August (205, 62%). The mean annual incidence was 0.09 cases/100.000 ranging between 0.06 cases/100.000 in 2016 and 0.15 cases/100.000 in 2018. The annual mean 6-year incidence was similar across age groups (0.07 cases/100.000 ≥80 years, 0.09 cases/100.000 in the 0-59 and 60-79 age groups).

Conclusions: TOSV infection is endemic in Italy, causing on average 50 cases of neuro-invasive disease each year. This likely under-estimates infections, as neuro-invasive cases are rare events, most TOSV infections are mild, and in our analysis we only considered laboratory-confirmed cases. Increased disease detection and international surveillance could improve our understanding of the public health impact of TOSV.

Popul. Med. 2023;5(Supplement):A303

DOI: 10.18332/popmed/164456

Incidence rates of gonococcal disease in a tertiary level hospital in madrid (Spain) between 2019 and 2022

Esther Expósito¹, Ana Sánchez¹, Rosa García¹, Aitana Vázquez¹

¹Hospital Universitario Gregorio Marañón Spain

Background and Objectives: Gonococcal infection is a sexually transmitted infection caused by the bacterium *Neisseria gonorrhoeae*, whose incidence has been increasing since the beginning of the century. Gonococcal infection can lead to serious complications such as pelvic inflammatory disease in women and orchitis in men. Given its importance at the Public Health level, the World Health Organization has included the control of this disease in the global strategies of the health sector for 2022-2030.

The main objective of this study is to analyze the incidence rate of *N. gonorrhoeae* reinfections and coinfections with *Chlamydia trachomatis* declared by a tertiary level hospital in the Community of Madrid since 2019.

Methods: This is a descriptive study of the declared cases of *N. gonorrhoeae* from January 1, 2019 to November 18, 2022. The rate of reinfections in a period of 1 year and the incidence rate of coinfections with *C. trachomatis* each year are calculated.

Results: There were 136 new *N. gonorrhoeae* infections in 2019, 93 in 2020, 228 in 2021 and 271 in 2022. The incidence rate of reinfections was 2.22% in 2020, 2.73% in 2021 and 4.35% in 2022. The incidence rate of coinfections with *C. trachomatis* has been 28.1% in 2019, 24.44% in 2020, 27.27% in 2021 and 25.56% in 2022.

Conclusions: The incidence rate of *N. gonorrhoeae* reinfections in a tertiary hospital has been increasing. The rate of co-infections with *C. trachomatis* has maintained levels, although there has been a significant decrease in incidence in 2020, which can be explained by the COVID-19 pandemic (decrease in social interaction, reduction of screening programs, closure of health resources, etc.). The decrease in the incidence rate of coinfections in 2022 can be explained by the sample size of this year, which only includes until mid-November.

Popul. Med. 2023;5(Supplement):A304

DOI: 10.18332/popmed/164516

Trends in confirmed cases of sexually transmitted diseases among notifications in a portuguese city, 2018-2022

Diogo Lopes¹, Francisca Valente², Ana Baptista¹, Dinis Loyens¹, Maria Borges², Paula Marques¹

¹Amadora Public Health unit Portugal, ²Amadora Public Health Unit

Background and Objective: Globally, sexually transmitted diseases (STDs) account for a significant number of morbidities and deaths. During the past few years, there has been an increase in the number of reported cases of STDs in Portugal. This study was designed to assess four-year trends in the percentage of confirmed STD cases among clinical notifications in a Portuguese city, from 2018 through December of 2022.

Methods: The Portuguese Epidemiological Surveillance System (SINAVE) provided data on STD notifications and confirmed cases. The data were analyzed to determine the percentage of confirmed cases among all notifications every year.

Additionally, the percentage of confirmed cases by specific STDs was examined. Results: Based on the results of the analysis, the percentage of confirmed STD cases in the city has increased from 2018 to 2022. A percentage of 68% of confirmed cases was reported in 2018, which increased to 74.4% in 2019 and 83% in 2020. Further increases occurred in 2021 and 2022, reaching 84% and 88.9%, respectively. This trend, however, differed in specific STDs, with syphilis increasing from 14% in 2018 to 68% in 2022.

Conclusion: It may be that the COVID-19 pandemic has had a restrictive effect on the number of confirmed cases. Many individuals with mild or no symptoms may have avoided seeking medical attention due to the pandemic, resulting in a higher percentage of confirmed cases. In part, this may be due to reduced access to medical care and diagnosis due to the pandemic, and some individuals may have neglected to visit a healthcare provider as a result. This has resulted in STDs that may otherwise have been diagnosed and treated early slipping through the cracks.

Prevalence and risk factors associated with schistosomiasis among women living with hiv/aids in lower moshi kilimanjaro, Tanzania

Anthony Charles¹

¹Temake regional referral hospital Department of microbiology and immunology P.O.Box 45232 Dar es salaam Tanzania

Background: Schistosomiasis infection has been associated with increased risk of HIV infection in African women. The co-infection between schistosomiasis and HIV /AIDS infection can be mediated through social behavioral factors. Cases show that over 200 million people are infected worldwide with a disproportionate burden in Africa, about 90% cases found alongside co-infection with HIV/AIDS.

Objective

To determine the prevalence and risk factors associated with schistosomiasis among women living with HIV/AIDS in lower Mosh- Kilimanjaro

Methodology: This study was a cross sectional hospital based analytical study, which was conducted in lower Moshi (Pasua, TPC, Arusha chini, Mabogini) from April to June 2021. The study population was HIV/AIDS infected women aged (15-49) years. A minimum of 260 women was enrolled in this study with a simple random sampling technique. A questionnaire was a tool for data collection. Data was entered and analyzed using SPSS version 20. Microscopic examination was performed to test for schistosoma infection where urine sample was used for detection of Schistosoma haematobium by membrane filtration method.

Results: A total of 260 participants were enrolled. The prevalence of schistosomiasis among HIV/AIDS positive women is 5% (13/260). There was an association between the outcome (schistosomiasis) and the previous infection of HIV/AIDS with a p-value <0.01.

Conclusion: The low prevalence of Schistosomiasis among HIV/AIDS women is 5% Only previous infection were associated with schistosomiasis. So strategic plans such as provision of Praziquantel drugs in the CTC and health seminars should be provided to residents in lower Moshi Kilimanjaro.

Protecting health workforce through vaccination in low and lower-middle income countries

Emma Patu¹, Jean-Marie Okwo-Bele², Wahid Marjooh³, Rocio Saenz⁴

¹World Federation of Public Health Associations, New Zealand, ²WHO Monkeypox Emergency Committee, WHO, Democratic Republic of Congo, ³Ministry of Health, Afghanistan, ⁴The Latin American Alliance for Global Health, Costa Rica

Outline: Protecting people worldwide with the appropriate vaccinations is a priority to save millions of lives. This is even more true for the healthcare and public health workforce, very often at the front line in caring for patients and communities. Indeed, the World Health Organization has prioritized healthcare workers for COVID-19 vaccine. While many countries, including those in less wealthy settings, often have infrastructures and policies to guarantee vaccinations for children, this is not always the case for adults nor for health workers. Indeed, in many countries a lack of infrastructures or appropriate policies undermine the access to vaccination throughout the life span. This means that high risks categories like the health workers are not protected creating a huge problem not only for the individual but for the whole society. Vaccine administration relies on existing immunization infrastructures. However, worldwide nearly 40% of countries have no immunization infrastructure to deliver adult immunization and almost 60% of the world's population lives in countries with no routine adult immunization programs. This applies also to the health workers. COVID-19 vaccines are being

administered in many low- and lower-middle income countries (LIC and LMIC) that do not have routine adult immunization infrastructure. This means also lack of mobilization and outreach, poor vaccine storage, handling, delivery, and waste management ability for this category. To administer COVID-19 vaccines to the adult populations, needed infrastructures and related activities should be developed. We should take advantage of this momentum to advocate for a sustainable development of infrastructures and measures to guarantee vaccination during the full life span, going beyond COVID-19 vaccine, starting with the health workforce. Aims: The World Federation of Public Health Associations (WFPHA) has worked together with its public health associations members to map out in which LIC and LMIC countries those structures are in place or under preparation to support the COVID-19 immunization, with the goal of encouraging the use of these resources to ensure sustainable routine immunization of health workers. Through literature review, WHO data analyses, survey among our members and focus groups, WFPHA has developed a series of recommendations to be used by national public health association to advocate with their government to reach this common goal.

Key questions: During the workshop, key opinion leaders from different regions will discuss the recommendations and share their experiences on how to develop, strengthen, and sustain immunization systems for health workers in LICs and LMICs and beyond to ensure routine immunization protecting health workers, patients and communities.

Strengthening Public Health Systems to Prevent and Respond to High-Consequence Biological Threats

Presenting Faculty¹, Paul Barach², Jan-Cedric Hansen³, Frank van Trimpont⁴, Donald Donahue⁵

¹Representing CREDO (<http://credoglobal.eu/>): * Paul Barach, MD, MPH * Jan-Cedric Hansen, MD * Frank van Trimpont, MD * Donald A. Donahue, DHEd, MBA, MSJ, FACHE, FRSPH, FICDM, ²Sigmund Freud University CREDO Austria, ³CREDO, France, ⁴European Council of Disaster Medicine, Belgium, ⁵University of Maryland Baltimore CREDO 18823 New Hampshire Avenue Ashton, MD 20861-9791 United States

Outline of the overall workshop

COVID-19 has revealed that national governments and the international community are woefully unprepared to respond to pandemics—underscoring our shared vulnerability to future catastrophic biological threats that could meet or exceed the severe consequences of the current pandemic. This workshop: * equips public health personnel for early identification of malicious use of the tools of modern biology, an accident-caused biological event, or a naturally occurring pathogen emerging in a novel manner; * familiarizes public health staff with concepts of One Health, disease spillover, and indices of suspicion; * prepares public health entities with effective communications approaches to convey the scope and severity of an outbreak; and * facilitates multi- and inter-disciplinary responses applicable across the whole of society.

Specific aims/objectives and component parts

Upon completion of this workshop, participants will be able to: * identify and analyze evidence of an emerging outbreak; * apply a participatory foresight, co-creative, future, and transformation-oriented methodology to structure a transformative model for a disciplined exploration of scenarios to confront complex challenges and facilitate improved outcomes; * evaluate current policy priorities and potential new policy directions; * see how the impact of possible policy decisions may combine with other developments; * inform, support, and link policymaking in and across a range of sectors; * identify societal demands and challenges; and * anticipate future developments, disruptive events, risks, and opportunities. The workshop begins with a scenario-based quiz, designed to illuminate disparate and often conflicting perspectives across civil society. Participants are familiarized with roles and responsibilities via Socratic roleplaying and provocative inquiry. Small groups are then assigned outbreak-related input and tasked to make recommendations to governmental leadership. Design of the scenarios is such that irreconcilable results emerge. Best practices are then reviewed, followed by a workshop-ending post quiz.

Key questions the workshop will address

The workshop engenders “mitigation scenarios” based on the “Confront, Regulate, Overcome” metamodel combined with the “Security, Rescue, Care” response modalities, helpful and required for cooperation and coordination of law enforcement, fire, civil security resources, hospitals, and first line responder teams. The exercise reveals gaps in national and international biosecurity and pandemic preparedness architectures. It explores opportunities for better cooperation to improve prevention and response capabilities for high consequence biological events and to generate actionable public health recommendations for the

international community.

Association of COVID-19 vaccination with herpes zoster: a systematic review and meta-analysis

Zhu Jiesisibieke¹

¹School of Public Health, The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, China

Background: Following COVID-19 vaccination, several herpes zoster cases have been reported, making it critical to explore the association between herpes zoster and COVID-19 vaccination. This is especially true in the context of increasing the number of participants enrolled to receive COVID-19 vaccination. **Research design and methods:** Three databases, including the Cochrane Library, PubMed, and EMBASE, were searched for relevant studies before 25 December 2021 according to preliminarily determined inclusion and exclusion criteria without any language limitations. Four cohort studies were included in this systematic review and meta-analysis.

Results: Compared with the placebo group, there was no evidence that the COVID-19 vaccination group was associated with increased incidence of herpes zoster (Risk ratio [RR]: 1.06; 95% confidence interval [CI]: 0.91 to 1.24). There is no evidence that the COVID-19 vaccination from Moderna is associated with the incidence of herpes zoster compared with vaccination from Pfizer (RR: 0.20; 95% CI: 0.01 to 2.99). **Conclusions:** To date, there is no evidence of an association between covid-19 vaccination and herpes zoster.

False-positivity Results in rapid antigen tests for SARS-CoV-2: an umbrella review of meta-analyses and systematic reviews

Yu-Pei Yang¹

¹Department of Hematology, Taizhou Hospital of Zhejiang Province affiliated to Wenzhou Medical University, Linhai, China

Purpose: The rapid antigen detection tests (RADTs) for SARS-CoV-2 infection could contribute to the clinical and public health strategies for managing COVID-19. This umbrella review aimed to explore the accuracy and sensitivity of RADTs for SARS-CoV-2 by assessing the incidence of false positivity associated with them.

Methods: Meta-analyses and systematic reviews on the sensitivity and specificity of commercially available RADTs with data on false-positive Results were identified by searching the PubMed, EMBASE, Cochrane Library, and Web of Science databases from inception to March 31, 2022. Data on the author and year, included studies, index tests, sample size, false negatives, false positives, and study quality based on AMSTAR 2 (Assessing the Methodological Quality of Systematic Reviews) rating were extracted from the included meta-analyses and systematic reviews.

Results: After a comprehensive literature search, 2670 studies were initially identified. After removing duplicates, 2288 studies were further screened. After title and abstract screening, 277 studies were considered for full-text review, of which 265 were excluded. Finally, 12 meta-analyses consisting of 422 articles were included in the umbrella review. The primary studies included in these 12 meta-analyses were observational studies with a comparison group and SARS-CoV-2 confirmed by RT-PCR or cell culture. The false-positivity rates in the included studies ranged from 0 (95% CI 0 to 1.0%) to 4.0% (95%CI 2.0%-5.0%). Based on the AMSTAR-2 criteria (Table 2), the quality of four, four, one, and three meta-analyses/systematic reviews were 'critically low,' 'low,' 'moderate,' and 'high,' respectively. **Conclusions:** The false positivity rates in the included studies ranged from 0.0% - 4.0%. This study summarizes the available evidence on the incidence of false positivity in RADTs and shows it is less than 4.0%. Therefore, our Findings imply that RADTs can be an appropriate, economic, and rapid detection method for mass screening of COVID-19.

Building a public health leadership curriculum for future pandemic preparedness

Lotte Pol¹

¹NorthWestern University, Malden, The Netherlands

The COVID-19 pandemic has emphasized the importance of effective public health leadership, and collaboration on multiple levels. Public- and global health leaders took many different approaches to reduce the spread of COVID-19. We investigated lessons learned about essential public health leadership skills through literature review, and through six 60-minute interviews with public health

leaders in Chicagoland area during the COVID-19 pandemic. Additionally, we developed a course syllabus to effectively teach public health leadership skills to future public health leaders. The developed leadership syllabus consists of four segments, discussing essential leadership skills in times of pandemic, outbreak investigation, global health disparities, and a personal leadership skill development plan. Teaching methods include case studies, narratives, reflections, podcasts, and teamwork assignments. We chose these methods because they will inspire students to further develop skills that will be necessary as a public health leader. Skills that should be taught to future public health leaders can be subdivided in five categories: social, emergency response, epidemiology, outbreak management, and technical skills. In particular, strong strategic thinking, teamwork, and communication skills are indispensable for a leader during a pandemic. Additional to essential skills, we identified certain personality traits that a public health leader should possess: such as flexibility, accountability, empathy, and having a clear vision. A limitation of our research is that we have only been able to perform six qualitative interviews, while the rest of our research was based on literature review of articles published during the COVID-19 pandemic. However, the qualitative interviews were performed with some of Chicagoland areas most influential leaders, for example Dr. Rachel Rubin and Dr. Kiran Joshi, Co-leads at the Cook County Department of Public Health. Sharing these essential public health leadership skills identified during the COVID-19 pandemic, and teaching them to future public health professionals can improve future pandemic preparedness.

COVID-19 rapid diagnostic test Results and their associations with certain factors among the residents of Balochistan

Ehsan Ahmed¹

¹FELTP Pakistan Health Department Government of Balochistan, Quetta, Pakistan

Background: This paper analyses any possible association of various factors like gender, last COVID-19 PCR test Results, BCG Vaccination, Seasonal Flu vaccination, occupation and confirmed case contact history with COVID-19 RDT Results of the participants. COVID-19 will soon become endemic in Pakistan, the government should adopt COVID-19 RDT kits for trace, test and quarantine activities.

Objectives: 1.To assess the odds for certain anti-COVID-19 IPC measures among the Contacts of an index COVID-19 case traced by Provincial Disease Surveillance and Response unit Quetta. 2.To provide evidence based recommendations for risk communication to the local context via media cell of the Health department of Balochistan

Methodology: Considering the availability of COVI-19 rapid diagnostic kits, 596 individuals all previously COVID-19 PCR tested were made part of this cross-sectional study. Simple random sampling was used for the selection of study participants. The whole study was conducted during September and October 2020.

Results: The major Findings of this study are clearly showing that the Positive Likely hood ratio of the COVID-19 RDT Kits (LR+) is well above 1; similarly, the negative Likely hood ratio is approaching 0. On the other hand, the sensitivity and specificity 80% and 74% respectively. Similarly, study found statistically significant association was between RDT out comes and last PCR Test status, occupation and contact with COVID-19 positive individuals. While other variables like gender, BCG vaccination and history of seasonal flu vaccinations were found to have no significant associations with COVID-19 RDT Kit out comes.

Conclusions: Being the first study of its kind in Pakistan the major Findings of this study are almost in line with the set hypothesis and Objectives of this study and based on study Findings it will be of high value to use COVID-19 RDT kits during mass screening especially during test, trace and quarantine activities.

DOI: 10.18332/popmed/164796

The impact of the COVID-19 pandemic on the residential aged care sector

Chebiwot Kipsaina¹, Angelita Martini²

¹Brightwater Research Centre, Curtin University, Australia, ²Brightwater Research Centre, Brightwater Care Group, The University of Western Australia, Inglewood, Australia

This scoping review sought to identify the impact of the COVID-19 pandemic on the residential aged care sector and facilities (RAC/F), using the World Health Organization's (WHO) health systems framework. It also sought to identify COVID-19 response strategies across the residential aged care sector, including

strategies that considered residents with cognitive impairment, who have been most impact by the COVID-19 pandemic. Databases were searched April-May 2022 for peer reviewed articles and grey literature, with additional searches on policy and service delivery to August 2022, with 147 articles included. The COVID-19 pandemic highlighted the lack of integration across health and aged care sectors, and issues with governance, accountability and comprehensive service delivery for RACFs. Response strategies that considered residents with cognitive impairment were limited. The need to ensure advance care and palliative care planning within COVID-19 responses was evident. Clear guidelines and additional resourcing are required for utilisation of telehealth during a pandemic, particularly to ensure access to diagnostic and treatment services for residents with cognitive impairment.

Vaccine hesitancy among the indigenous tribes of North East India: an incipient crisis

Ningombam Devi¹, Shanthosh Sundaram²

¹North Eastern Indira Gandhi Regional Institute of Health and Medical Sciences, Shillong, India, ²North Eastern Indira Gandhi Regional Institute of Health and Medical Sciences, India

Background: Vaccine hesitancy has become an important concern to public health as it carries both individual and community level risks; however, it lacks proper assessment till date. Understanding the burden and the reasons for the same thus becomes a key for an effective solution toward the COVID vaccination among the indigenous tribal community.

Methods: A community based sequential explanatory mixed methods study was conducted among 238 eligible indigenous Khasi tribes of Meghalaya, North East India. The quantitative part involved a cross-sectional study to determine the proportion of vaccine hesitancy and the qualitative part comprised of in-depth interviews among the eligible residents and key informant interview among the health workers providing the vaccination services, to explore the facilitators and barriers of vaccine uptake.

Results: A total of 113 [47.5% (95% CI: 41.0%-54.0%)] participants were found to be hesitant to vaccination, among which 40 [16.8% (95% CI: 12.4%-22.3%)] were initially hesitant and 73 [30.7% (95% CI: 24.9%-37.0%)] had vaccine refusal. The themes generated through qualitative interviews were individual related, disease related, vaccine related, healthcare system and provider related and socio-cultural and religious. The main barriers were identified under perceived susceptibility and perceived severity under the individual perception along with ambiguity aversion, scepticism about the efficacy, mistrust, concerns on side effects, rumours and socio-cultural and religious misbeliefs acting as major perceived barriers for likelihood of action. Some of the facilitators were literacy, health consciousness, family motivation and perceived benefit on effectiveness.

Conclusions: and recommendations: Vaccine hesitancy is found to be relatively higher for the indigenous tribes and it depends on complacency towards the vaccine, confidence on its safety, perceived susceptibility and severity to the disease coupled with modifying factors for cues for action. Healthcare workers should better communicate to improve the uptake of vaccine by reducing the barriers on the vaccine acceptance.

DOI: 10.18332/popmed/164825

Stress, coping and psychological wellbeing of postgraduate student in Ireland during COVID 19 pandemic

Afroja Ahmed¹

¹School of Public Health, Physiotherapy and Sports Science University College Dublin (UCD), Ireland

Present research aimed at identifying how postgraduate students in Ireland were coping with stress and the relationship between coping strategies to wellbeing, considering the context of the covid 19 pandemic. The purpose of the current study was to determine the extent to which diverse postgraduate students were experiencing a various range of covid related stress, how do they cope with stressors and its relationship to their wellbeing. It was a cross-sectional and correlational study where measures of covid stress, coping strategies, psychological well-being and key demographics were collected through an online survey. Data were collected via UL Qualtrics by inviting postgraduate students of the University of Limerick (UL) in Ireland through email and social media posts. Total 109 postgraduates of UL participated in the research and data were analyzed by using SPSS (version 23). To test the hypotheses of the study, Hayes' process macro for mediation and moderation analysis in SPSS was employed. Findings demonstrated that covid stress was undermining the wellbeing of postgraduate

students and informal coping strategies mediate the relationship between stress and wellbeing. Here informal coping strategies indicated exercise, listening to music or spending time with housemates for leisure activities. Whereas, formal emotional coping strategies (i.e. counseling) didn't either mediate or moderate the relationship between stress and wellbeing. However, majority of the student agreed that online anonymous wellbeing services would be beneficial for them to deal with covid related stress. Present study shed light emphasizing diverse postgraduate students' wellbeing, and their emotional needs and support services at Irish Universities as Ireland is a global hub for highly diverse international students. This study developed two new covid related scales (i.e. stressors and coping scale) which also has a proffered practical and policy implications for the post-pandemic era.

Outcomes of home isolated COVID-19 patients and risk factors associated with the adverse outcomes: Longitudinal Retrospective Study in Shimoga, Karnataka

Sakshi Kumari¹

¹Shimoga Institute of Medical Sciences, Shimoga, India

Background: COVID-19 is a current global pandemic caused by the newly discovered novel SARS-COV-2. According to studies, patients who have died thus far were older, more likely to be male, and to have a comorbidity such as hypertension, diabetes, cardiovascular disease, or lung disease thus necessitating the assessment of risk variables in various demographic groups or contexts. **Aims:** 1. To estimate the proportion of different outcomes such as recovery, hospitalization, and mortality among home isolated covid-19 patients, 2. To estimate the proportion and to determine various risk factors associated with COVID-19 adverse outcome.

Methodology: The study was carried out in Shimoga Institute of Medical Sciences, Shivamogga, Karnataka. Data was collected by telephonic Interview. **Study design:** Longitudinal retrospective study. **Study Population:** Home isolated COVID-19 patients. **Inclusion criteria:** All COVID-19 patients registered in triage of MCGann hospital, during April 20th-June 20th 2021. **Exclusion criteria:** People who did not consent, or were suffering from mental illnesses, or did not respond **Study period:** April 20th-June 20th, 2021. **Sample size:** 168. **Sampling:** All the patients who reported in MCGann triage during April 20th-June 20th, 2021.

Results: A total of 168 people participated in this study, with 93 men (55.3%) and 75 women (44.7%). More than 90% of patients in the Home Isolated COVID 19 patients recovered, 10.75% required hospitalisation, and 3% died. One third of the patients (37%) had one or more comorbidities. **Conclusions:** Our study shows that older age, male gender and comorbidities have higher hospitalisation rates. Comorbidities and older age were associated with a higher risk of death in hospitalised patients. Even though recovery rate is very high, a significant (10.75%) home isolated patients need hospital admission in the disease course. So, the proper monitoring of home isolated patients can save the lives of many COVID-19 patients.

Popul. Med. 2023;5(Supplement):A316

DOI: 10.18332/popmed/164837

Psychological impact of the early stage of the COVID-19 outbreak, what have we learned? A systematic review

Henoch Cswaka^{1,2}, Fils Hyute¹, Newton Mupungu³, David Bayenga³, Roger Kabuya⁴, Esperance Kashala-Abotnes^{5,6}

¹Faculty of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of Congo, ²Academy of Science and Engineering for Africa Development, Kinshasa, Democratic Republic of Congo, ³Faculty of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, ⁴Pinecrest-Queensway Community Health Centre, Ottawa, Canada, ⁵University of Bergen, Centre for International Health, Bergen, Norway, ⁶Department of Neurology, Kinshasa University Hospital, Kinshasa, Democratic Republic of Congo

Background and objectives: As in previous pandemics, the COVID-19 outbreak has been inflicting different mental disorders upon people. As it was a question of a new virus, research had to be carried out to promptly react to this global crisis. Significant effects of COVID in its earlier stage such as high mortality, speed of transmission, no cure had led to a novel psychological pandemic that made the COVID-19 pandemic management more difficult. The Objective of this systematic review is to explore the global view of the psychological impact of the COVID-19 pandemic in its earlier stage.

Methods: A systematic search of PubMed, EMBASE, and Google Scholar databases was performed up to June 20, 2020. Three authors evaluated full-text articles regarding predefined criteria. We utilized a modified version of the

Newcastle-Ottawa Scale for observational studies to assess the risk of bias. The review protocol is registered and available online in PROSPERO.

Findings: This systematic review included participants from all over the world except Africa and Oceania. Fifty-four descriptive studies were included in the review. Overall, the analysis from this review suggested that there is a lack of sufficient robust evidence to confirm the association between the COVID-19 pandemic and mental impact. However, most of the studies pleaded for the assumption that the pandemic affected the mental health of the population throughout the world.

Conclusions: Governments and decision-makers are required to respond promptly to any eventual outbreak to ensure the populations mental health well-being through some strategic planning and prevention.

Keywords: systematic review, COVID-19, mental health, psychological impact, psychological symptoms

Knowledge and attitude of COVID-19 preventive practice in Mongolia

Buuveidulam Altansukh¹, Suvd Batbaatar¹

¹National Center for Public Health, Mongolia

As of September 21, 2021, 65.3 percent of Mongolias population was vaccinated at full dose. However, as of COVID-19 confirmed cases, Mongolia is in the top five countries in the West Pacific. This indicates that there is a lack of practice to prevention from coronavirus infection in the population. This survey Aims to compare the level of attitudes, and practices of the population towards coronavirus infection with the Results of the baseline survey Results; and disseminate evidence-based recommendations for decision-makers who are dealing with the pandemic. The cross sectional method used for data collection and analysis was conducted using SPSS-23. A total of 1896 people aged 15-60 years old participated in the study. The 56.6% were from Ulaanbaatar and 43.4% were from rural areas. Compared to the baseline survey Results, in the follow-up survey, practices of wearing masks in the workplace or indoor environment (73.0%) had increased. Most of the population surveyed is aware of ways to preventive measures of infection.

Popul. Med. 2023;5(Supplement):A318

DOI: 10.18332/popmed/164878

Informational and structural barriers to uptake of preventive behaviours among Healthcare workers working in both isolation and non-isolation sites during COVID 19 in Zambia

Mwiza Nyasa¹

¹Centre for Infectious Disease Research in Zambia (CIDRZ), Zambia

Healthcare workers (HCWs) are at higher risk of contracting COVID-19 due to the nature of their jobs, handling patients in proximity. We aimed to explore HCWs perspectives on their knowledge, skills needs, attitudes towards, and their ability to practice preventive behaviours in the context of COVID-19 in Zambia. 20 in-depth interviews (IDIs) via phone. 10 from an isolation facility and 10 from a non-isolation facility.

Preliminary results: HCWs had sufficient information on how COVID-19, is transmitted, managed, and prevented. Some participants received training on oxygen therapy, infection prevention practices, donning and doffing and admission of critically ill patients but would want more continuous training. Facility changes such as increased staffing, outdoor screening tents, temperature checks helped reduce the spread in the facilities. HCW continued to practice infection prevention to protect themselves from COVID-19 but faced challenges of insufficient, supplies and equipment to meet prevention needs and treat COVID-19 patients and NCD patients were some of the noted challenges faced in the prevention and management of COVID-19. HCW also mentioned the emotional stress of treating patients, especially during the surge, where they felt overwhelmed and anxious handling patients and felt the need to have mental health services offered to them recommended that for them to be adequately protected they needed an adequate and consistent supply of well-fitting PPE, tests kits and medication for comorbid diseases like diabetes and hypertension and availability of products to enhance infection prevention control such as running water, soap, hand sanitisers, and gloves.

Conclusions: HCWs in all health facilities need continuous training, as COVID-19 evolves. There is a need for supply of quality well-fitting PPE, more rapid test kits and a sufficient supply of medication for comorbid diseases will also aid in ensuring a reduction in transmission of COVID-19 in facilities.

Popul. Med. 2023;5(Supplement):A319

DOI: 10.18332/popmed/164901

Exploring COVID-19 riskscapes in Ghana, Cameroon, and Malawi

Nathanael Ojong¹, Efram Agbe¹

¹York University, Canada

Extensive immunisation plays a critical role in preventing, containing, and stopping transmission of COVID-19, and the success of extensive immunisation hinges on individual acceptance of these approved vaccines. However, in several African countries, people's reluctance to receive the recommended vaccines remains a major concern. This paper uses a qualitative research approach that included 144 semi-structured interviews to investigate the ways people in Ghana, Malawi, and Cameroon construct and understand risk related to COVID-19 and recommended vaccines. Using the concept of riskscapes, our Findings bring to the fore an alternative geographical understanding of COVID-19 viral spread and COVID-19 vaccines, where spatial, relational, and temporal dimensions of risk are intimately interwoven. Spatiality was important to people's understanding of risk. People's understanding of COVID-19 viral spread and COVID-19 vaccine risks was tied to specific sites and landscapes. The Findings show that vaccine safety goes beyond clinical and regulatory authority approvals; it encompasses forces which are socio-spatial in nature. Additionally, our Findings highlight how power relations are manifested at macro- and micro-structures and operate through different channels to influence COVID-19 vaccine acceptance and rejection. We contend that the multiple manifestations of power relations have implications regarding the individualisation of risk. In some situations, people manifest autonomy regarding managing risk and in other cases that autonomy is challenged through macro and micro power structures. Promoting COVID-19 vaccine uptake requires understanding the socio-spatial perceptions of risk. An in-depth understanding of localised perceptions of COVID-19, including COVID-19 vaccines, leads to contextualised and local public health responses to tackle the current pandemic and future ones.

Popul. Med. 2023;5(Supplement):A320

DOI: 10.18332/popmed/164919

Multidisciplinary rehabilitation in intensive care for COVID-19 - a randomized controlled trial

Ana Carvalho^{1,2}, Pedro Cantista^{2,3}, Catarina Branco⁴, Bruno Guimarães⁴

¹Unidade de Saúde Pública Porto Oriental, Portugal, ²Instituto de Ciências Biomédicas Abel Salazar, Portugal, ³Centro Hospitalar Universitário do Porto, Portugal, ⁴Centro Hospitalar Entre Douro e Vouga, Portugal

Background and Objective: The coronavirus disease 2019 (COVID-19) has led to an increasing number of patients in the intensive care units (ICU). The size of this post-ICU cohort will be unprecedented, with many patients vulnerable to post-intensive care syndrome. PICS is recognized as a growing public health burden due to the associated neuropsychological and functional disability, and the evidence suggests that the prevention from ICU admission is more important and effective than intensive treatment of PCIS following ICU discharge. The objective of this study was to analyze the respiratory and functional effects of a rehabilitation program on functional performance, in patients hospitalized in ICU due to COVID-19. Methods: We conducted a randomized controlled clinical trial. Ninety-six patients, who fulfilled the eligible criteria, were randomized into control or intervention group. The control group received standard of care in the ICU, and the intervention group received a functional and respiratory rehabilitation protocol, that included medical, nursing, physiotherapy, and occupational therapy interventions.

Results: At discharge, the intervention group showed significantly better muscular strength and respiratory capacity, and significantly less days of hospitalization (12.90±5.8 vs 15.60±6.7 days, P=0.037). At the 4- and 12-week follow-up we applied our main outcome measure – 6-minute walking test. The intervention group had significantly better Results than the control group on the 6-minute walking test at the 4-week follow-up (604±67 vs 571±57 m, P=0.018) and at the 12-week follow-up (639±53 vs 611±67, P=0.025). Conclusions: These results support the role of a multidisciplinary rehabilitation program in COVID-19 patients hospitalized in ICU and adds evidence that the implementation of rehabilitation programs in ICU could Results in beneficial outcomes for the critical ill patients.

DOI: 10.18332/popmed/164937

Assessment of the usability of SARS-CoV-2 self-tests in a peer-assisted model among factory workers in Bengaluru, India

Meghana Pydi¹, Neha Parikh²

¹Swasti Health Catalyst, Bengaluru, India, ²Swasti Health Catalyst, Karnataka, India

Background: The covid-19 pandemic exacerbated inequities in healthcare for vulnerable populations and exposed structural gaps in the health system in India.

During the pandemics peak, access to quick, accurate, and affordable testing method was scarce due to overburdened public and private testing centers. Self-testing kits for home-based use for detecting the sars-cov-2 virus were introduced as a tool to bridge the gaps of conventional testing. This study aimed to determine the usability of SARS-COV-2 self-tests in a peer-assisted model among factory workers in Bengaluru, India. Methods: This mixed-method cross-sectional study of 106 factory workers in Bengaluru, India evaluated the usability of a nasal sampling-based covid-19 antigen self-test kit (PANBIO™) in a peer-assisted model from February to march 2022. An observer used a product-specific usability checklist consisting of critical and non-critical steps in the IFU to record the usability of the test kit and the mobile application as the participant performed the test with peer assistance.

Results: the average usability score of the test kit was 80.69% and the average usability score for uploading results through the mobile application was 34.01%. 82.07% of the participants correctly interpreted pictures of positive results with 62.0% of participants being confident in performing and interpreting the test with the assistance of a peer. Whereas, 43.9% of participants were confident in performing and interpreting the test on their own suggesting that peer assistance is a key determinant for the usability of self-tests in marginalized populations. Conclusions: Results of the usability and acceptability study suggest that a nasal sampling-based self-testing kit for covid-19 shows overall moderate to high levels of usability and high levels of acceptability in a peer-assisted workplace testing model. Determining the feasibility of implementing this model at scale is the next step to inform and advocate for other workplace self-testing programs for vulnerable populations.

Inflammatory markers and hematologic indices in the prediction of severity of COVID-19: a single center study in Southern Philippines

Meccar Elino¹, Michael Pecaoco¹

¹Department of Health, Southern Philippines Medical Center, Davao City, Philippines

Various diagnostic tests across COVID-19 literatures were employed as surrogate markers in COVID-19, wherein interleukin-6 (IL-6) – gauge for cytokine storm or impending severity – is not readily available on third world countries particularly Philippines. This study determined the clinical value of inflammatory markers and hematologic indices as warning indicators in the prediction of severity of COVID-19 infection. Cut-off values were also determined. Methods: Demographics, baseline inflammatory markers and hematologic indices were retrieved from the database covering April-December 2020 as a single-center retrospective cohort. Univariate, Multivariate, and Receiver Operator Characteristic analyses were done. There were 1,368 patients: 845 nonsevere cases (61.77%) and 523 severe cases (38.23%). Diabetes, hypertension, leukemia, cancer, cardiovascular disease, chronic lung disease, liver disease and chronic kidney disease are seen more in severe group. HIV did not establish significant difference between two groups. Markers C-reactive protein (CRP), lactate dehydrogenase (LDH), ferritin & procalcitonin; and indices neutrophil-to-lymphocyte ratio (NLR), fibrinogen, & D-dimer are significantly higher in severe group. Diabetes (OR 2.19, 95% CI 1.01-4.76 p<0.05) and cancer (OR 4.58, 95% CI 1.24-4.76 p<0.05) emerged as potent independent risk factors for COVID severity. CRP (OR 1.24, 95% CI 1.12-1.37 p<0.05), LDH (OR 1.02, 95% CI 1.001-1.004 p<0.05), and ferritin (OR 1.004, 0.998-1.009 p<0.05) show the highest predictive value in developing severe COVID-19. Optimal cut-off values predictive of severity were determined more than 1.85 mg/dL for CRP (79% Sensitivity, 84% Specificity), more than 644.85 U/L for LDH (78.7% Sensitivity, 81.6% Specificity), and more than 621.4 ng/mL for ferritin (71.3% Sensitivity, 74.8% Specificity). Nonsevere cases with diabetes, cancer, and high levels of CRP (>1.85 mg/dL), LDH (>644.85 U/L), and ferritin (>621.4 ng/mL) have high predilection to become severe or O2-requiring in the course of infection. Utmost caution and monitoring at the onset are warranted.

Hand Hygiene (HH) pre and post-SARS-CoV2 pandemic: What are we missing?

Valeria Reynolds-Cortez¹, Maria Haro², Maria Carralero-Palomero^{3,4}, Mar Gomez-Santillana^{5,6}, Edgar Silva-Contreras^{5,6}

¹Servicio de Salud de Castilla-La Mancha (SESCAM), Spain, ²Hospital Virgen de la Luz, SESCAM, Cuenca, Spain, ³Servicio de Salud de Castilla-La Mancha (SESCAM), Spain, ⁴Hospital Virgen de la Luz, Spain, ⁵SESCAM, Spain, ⁶Hospital Virgen De La Luz, Spain

Healthcare-associated infections (HAIs) are a public health problem. Many of the HAIs are preventable by following the 5 Moments for HH from WHO. We compared the degree of compliance of HH(DCHH) and the consumption of alcohol-based solutions (ABS) in our hospital in the years 2017-2019 (pre-pandemic) and 2021 (post-pandemic). The observation of DCHH was carried out annually from 2017-2021 according to the WHO methodology; with the exception of 2020 due to the pandemic. ABS consumption is reported by the purchasing department and is an indirect indicator of the DCHH. The variables studied are: Consumption of ABS in liters x 1000/Patient Days per year (LPP); Number of HH actions observed (HAO) x 100/Number of HH opportunities observed per year for each of the 5 moments from WHO. For the analysis we used the program SPSS 24.0, x2 or t-student with [IC95] and p<0.05. In 2017, LPP was 11.9% (925200/77227); overall HAO 31.8% (84 actions/264 opportunities); Indication 1(I1) 28.3%(30/106); Indication 2(I2) 14.7% (5/34) Indication 3(I3) 11.1%(2/18); Indication 4-5(I4-5) 44.3%(47/106). 2018: LPP was 44.2% (3376600/76475), overall HAO 48.2%(370/768); I1 41.9%(136/325); I2 56.4%(22/39); I3 56.9%(45/79); I4-5 51.4%(167/325). 2019: LPP was 12.5%(839487/67153); overall HAO 31.5%(218/692); I1 25.0%(73/292); I2 6.5%(2/31); I3 2.6%(2/77); I4-5 48.3%(141/292). 2021: LPP was 9.5%(669580/70161); overall HAO 38.5%(119/309); I1 27.8%(27/97); I2 18.6%(11/59); I3 39.3%(22/56); I4-5 60.8%(59/97). LPP from 2017-2019 was 23.2%(5141287/220855) vs. 2021's 9.5%(669580/70161). For the year 2021, the global HAO RR 0.9[0.5-1.2] p =0.8; I1 RR 0.8[0.5-1.2] p =0.3; I2 RR 0.7[0.9-2.2] p=0.2; I3 RR 1.4[0.9-2.2] p=0.1; I4-5 RR 1.5[1.1-2.2] p<0.05. LPP for 2021 was lower (9.5%) than in pre-pandemic years (23.2%). The I4-5 was significant. Healthcare workers appear to perceive the potential risk of cross-transmission only after making contact with the patient, or perhaps their actions are based on self-protection. It is essential to continue training in HH in favor of patient safety.

Loneliness across the COVID-19 Pandemic: an Irish cohort study.

Joanna Power¹, Philip Hyland¹, Michael Daly²

¹Department of Psychology, Maynooth University, Maynooth, Ireland,

²Department of Psychology, Maynooth University, Maynooth, Republic of Ireland

Background and Objectives: Loneliness and existential loneliness are undesirable states which may have been inflated during the COVID-19 pandemic across the population. The Objective was to assess trajectory of loneliness among Irish adults during the COVID-19 pandemic, predictors of baseline and changes in loneliness over time, and to evaluate existential loneliness towards the end of the pandemic, and its correlates.

Methods: Longitudinal panel data were gathered from 1041 participants aged 18-80 from 31st March 2020 across four waves. Latent growth models in a structural equation modelling context were used to evaluate change in loneliness over time. A separate structural equation model was used to evaluate correlates of existential loneliness.

Results: At a group level there was little change in loneliness over time (estimate = 0.04) and participants were on average moderately lonely at baseline (intercept estimate = 1.62). At baseline loneliness was associated with: being younger, not being in a relationship, being employed in healthcare, lower levels of neighbourhood belongingness, social contact from family, and higher levels of depression. Change in loneliness was associated with: being employed in healthcare (negative change, possibly regression to mean), and depression levels (negative change, again likely regression to mean). Existential loneliness was associated, cross-sectionally, with loneliness (beta = .46), depression (beta = .31), sex (beta = -.134), age (beta = -.19), relationship status (beta = .14), and empathy (beta = -.151).

Conclusions: We describe correlates of loneliness in the first Irish lockdown of 2020, as well as predictors of changes in loneliness across the pandemic, and correlates of existential loneliness at a later stage in the pandemic. Results indicate that those working in healthcare in particular had highest levels of loneliness during the first lockdown. Results are discussed in the context of potentially informative theoretical frameworks of loneliness.

Characteristics and outcomes of COVID-19 among people living with HIV at Eka Kotebe General Hospital, Addis Ababa, Ethiopia

Nebiyat Ahmed¹
¹Department of Internal Medicine, Eka Kotebe General Hospital, Ethiopia
Introduction: Evidences about the interplay between HIV and COVID-19 are not entirely consistent.

Objectives: Compare the adverse outcomes of COVID-19 among people living with and without HIV/AIDS and explore factors that determine outcomes. **Methods:** We conducted a retrospective cohort study on medical records of patients who had a positive RT-PCR for COVID-19 and were admitted to Eka Kotebe General Hospital from March 2020 to October 2021.

Results: Four hundred twenty-seven, 108 exposed (people living with HIV/AIDS) and 319 non-exposed (people without HIV/AIDS) were included in the study. The median age for PLWH and people without HIV was 49.5 (40–59) and 48 (32–65) respectively. Of those, 258 (60.4%) were male. There were significant differences between PLWH and people without HIV in terms of age, TB, pregnancy, chronic liver disease, complications, shock, WBC count, and end outcome (alive or dead). There was no association between HIV status and the need for oxygen, ICU admission, and disease severity. After adjusting for other variables, mortality was significantly higher among PLWH (AOR = 2.25, 95% CI 1.11–5.56, $p=0.023$). **Conclusions:** PLWH with COVID-19 have a higher rate of in-hospital mortality than people without HIV, although there was no association between HIV status and the requirement for ICU admission, mechanical ventilation, oxygen support, or the severity of the disease at the time of admission.

Social connectedness and emotional health during the COVID-19 pandemic: a population-based latent profile analysis examining changes in connectedness and emotional health among adolescents in British Columbia, Canada

Eva Oberle¹, Maram Livermore¹, Tonje Molyneux¹, Ryan Ji¹

¹The University of British Columbia, Canada

This study examined profiles of social connectedness among early adolescents in grade 7 before the COVID-19 pandemic was declared (Winter 2020), and again in grade 8 during the second Wave of the pandemic (Winter 2021), applying a person-centered approach. Linked data from 1753 early adolescents (49% female) from British Columbia (BC), Canada who completed the Middle Years Development Instrument (MDI) survey in grade 7 and 8 were used. Elementary and middle schools in the province of BC were open for in-person instruction during the 2021 school year. Students reported on positive (life satisfaction) and negative (depressive symptoms) mental wellbeing indicators and connectedness with peers, and adults at home, school and in the community. Latent Profile Analysis was performed to identify profiles of connectedness for students in grades 7 and 8. Latent Transition Analysis was performed to examine transitions in connectedness profiles from grade 7 to grade 8. Multiple regression analyses examined the associations between profile membership in grade 7 and mental wellbeing in grade 8. Further analysis examined the association between transitions in profile membership between grades 7 and 8 (i.e., increases versus decreases in connectedness over time) and mental wellbeing in grade 8. We found that connectedness in multiple domains in grade 7 was related to significantly higher levels of mental wellbeing in grade 8, controlling for early adolescents' demographic Background, wellbeing in grade 7, and COVID-related mental health worries. Wellbeing was highest for those who felt highly connected in all domains and lowest for those who felt consistently lower levels of connection. Profile membership was relatively stable over the two time points. However, for those who transitioned to a different connectedness profile, increases in connectedness were related to improvements in mental wellbeing and decreases were related to a decline in wellbeing over time.

Strength of community engagement in controlling and preventing COVID-19 in a highly vulnerable Māori populated region in New Zealand

Anura Jayasinghe¹, Hine Moeke-Murray²

¹Health New Zealand, Tairāwhiti, Gisborne, New Zealand, ²Te Kupenga Net Trust, New Zealand

Background and objectives: Tairāwhiti district in New Zealand has a unique demographic and geographic makeup in which Māori represent 53% of the population and are disproportionately represented in adverse health and social outcomes. In this context, an equitable response was required to ensure all families and communities could access timely support to minimise the impact of COVID-19, despite existing stressors, including comorbidities, economic deprivation and housing stress. The programs primary Objectives are to establish a community-led, clinically partnered and locally structured program to respond to the COVID pandemic, to coordinate responses to reduce the risk of fragmented service to families, and to mitigate community transmission of COVID.

Methods: Public Health identified a well-established community organisation

named "Te Kupenga Net Trust" which had already delivered a range of welfare services to indigenous population groups in the region. Representatives of the leading partners engaged with the trust, and the service structure was transformed into a COVID service provider named "Takātū Hub". Public Health and the main co-partners through the Takātū Hub provided welfare, psychosocial support, primary care, testing and isolation.

Results: The majority of 16,784 local COVID patients and their families received immediate medical and welfare advice from the service. Tairāwhiti Māori COVID hospitalization rate is remarkably lower (1.8/1000) than the national rate (3.08/1000). This could be related to better community care in Tairāwhiti through this specific programme. This programme generated other positive effects, such as: a new and unique workforce trained with the agility and ability to respond to exceptional circumstances, strengthened relationships between agencies, and shared learnings and successes evident in different parts of the service continuum.

Conclusions: This exercise has demonstrated that localised and community-led establishments can be transformed into other health settings in public health crises and provide community support and care to reduce hospitalization.

Effects of COVID-19 vaccination type and doses on symptoms and hospitalization of healthcare professionals having SARS-CoV2 infection

Fatma Akcakaya¹, Bedia Ozyildirim¹, Sezanur Turkoglu², Ceyda Acar²

¹Department of Public Health, Faculty of Medicine, Bezmialem Vakif University, Türkiye, ²Department of Public Health, Faculty of Medicine, Bezmialem Vakif University, Türkiye

Background: It is an important issue for public health to protect healthcare professionals who are fighting the virus most closely in the COVID-19 pandemic from illness and hospitalization with vaccines. It was aimed to investigate the effects of different types and numbers of vaccines administered for COVID-19 in isolated healthcare professionals in Turkey on symptoms and hospitalization. **Methods:** Between February 2021–March 2022, questionnaire were applied to healthcare professionals who tested positive for COVID-19 infection, at home or on the first day of the isolation process in the hospital, by telephone interview. The data obtained were evaluated as a retrospective cohort study.

Results: 71.3% of the people in the study (N=690) were female, mean age was 31.6 ± 8.9 years. 634 people (91.9%) said they had at least one dose of vaccine, 150 people (21.7%) said they had COVID at least once before our follow-up. 182 people (26.4%) who had at least one dose of vaccine received only sinovac vaccine, 112 people (16.2%) received only biontech vaccine and 293 people (42.5%) received both vaccine types. The most common symptoms on the first day of our calls among 690 people were nasal discharge/congestion (58.8%), cough (57.0%), musculoskeletal pain (56.5%), sore throat (55.5%) and fever/chills/chills (43.2%). After the diagnosis of COVID-19 14 people (2.0%) were hospitalized. Hospitalization was found to be statistically higher in those who were not vaccinated ($p=0.003$). The rate of loss of taste and smell and dizziness were found to be statistically higher in the unvaccinated compared to the vaccinated (respectively $p=0.036, 0.032, 0.030$).

Conclusions: The high rate of hospitalization, loss of taste and smell, and dizziness in unvaccinated patients is an important indicator of workforce loss in healthcare professionals and poses a serious threat to public health. Giving priority to healthcare professionals in vaccination programs is extremely important for the uninterrupted continuation of health services in future pandemics. The continuation of this study with a larger sample is a significant issue that should be considered in terms of protecting public health.

Pediatric COVID-19 population in Tunisia from 2020 to 2022 : clinical characteristics and risk factors of severity

Arwa Neffati¹, Hela Ghali², Rania Bannour¹, Sana Bhiri³, Aroua Kamel³, Emma Hariz², Fatimaezzahra Khouya³, Souhir Ayadi³, Salwa Kefacha³, Asma Cheikh³, Houyem Said³

¹Department of Prevention and Safety of Care, Sahloul University Hospital, Sousse, Tunisia, ²Department of Prevention and Safety of Care, Sahloul University hospital, Sousse, Tunisia, ³Department of Prevention and Safety of Care, Sahloul university hospital, Sousse, Tunisia

Background: Tunisia was one of the countries with the highest COVID-19 mortality worldwide. Although clinical characteristics and risk factors for severe disease in COVID-19 patients have been described in many studies, works on the pediatric population are still scarce. **Objectives:** The aim of our study was to describe

the clinical characteristics of COVID-19 in pediatric patients in a tertiary care center since the start of the pandemic until the end of hospitalization to identify their association to severe forms. Methods: Since the start of the pandemic, the prevention and security of care department has been recording all new cases of COVID-19 hospitalized in the various units in which these patients were hospitalized. Daily monitoring of the evolution of the patient's conditions was provided by the hygienist technicians of our department.

Results: Overall, 180 confirmed COVID-19 pediatric patients have been admitted in our hospital. Most patients were male (51.1%); the median age was 1[1; 8] years. The median length of stay was 3 days [2-8]. Comorbidities were present among 43.9%: renal diseases (13.3%), coronary artery diseases (11.7%) and neurological diseases 6.7%. Most patients had an important degree of hypoxemia, with 12.8% of them requiring supplemental oxygen, and 4.4% needed intubation. The overall case fatality rate was 6.7%. The multivariate analysis revealed Independent risk factors which were: male gender ($p: 0.019$, OR 1.363, IC [1.053-1.765]); use of nasal cannula ($p=10^{-3}$; OR: 2.025, IC [1.397-2.933]); optiflow ($p<10^{-3}$, OR :11.042, IC [6.366-19.155]); noninvasive ventilation ($p<10^{-3}$, OR 24.14, IC [13.78-42.29]); comorbidities ($p=0.001$, 1.733[1.24; 2.42]) such as Hypertension, diabetes($p=0.016$, 1.44[1.07;1.93]), neurological disorders ($p=0.025$; 1.64[1.06; 2.53] and obesity ($p<10^{-3}$; 3.94[1.83;8.45]). Conclusions: identifying these risk factors is of tremendous importance to improve the management of pediatric patients at risk of severe forms and to guide the development of preventive measures.

Voices of Society: the emergence and contributions of civil-society practices aiming to engage in COVID-19 management

Sophie Kemper¹, Renate Broek², Sarah Hameren³, Frank Kupper⁴, Marloes Bongers^{5,6}, Marion Vries^{5,6}, Aura Timen⁷

¹National Coordination Centre for Communicable Disease Control, National Institute for Public Health and the Environment, Bilthoven, The Netherlands,

²National Coordination Centre for Communicable Disease Control, The National Institute for Public Health and the Environment, Bilthoven, The Netherlands, ³National Coordination Centre for Communicable Disease Control, The National Institute for Public Health and the Environment, Bilthoven, The Netherlands, ⁴Athena Institute, Faculty of Science, VU University Amsterdam, Amsterdam, The Netherlands, ⁵National Coordination Centre for Communicable Disease Control, National Institute for Public Health and the Environment, The Netherlands, ⁶National Centre for Public Health and Environment, The Netherlands, ⁷Department of Primary and Community Care, Radboud University Medical Center, Nijmegen, The Netherlands

Background: In COVID-19 management (CM) complex trade-offs are made between health, society, and economy. During the pandemic, parts of the public have mobilized themselves in civil-society engagement practices (CSEPs), to improve or suggest alternative CM-practices. This study explores the motivators to establish CSEPs aiming to influence CM and their perceived contributions to CM, with the main aim to study whether integrating views of CSEPs has added value in CM. Methods: A systematic online search identified eligible CSEPs in the Netherlands. Their corresponding characteristics were mapped based on publicly available information, such as local/national scope, the topic of focus in CM, and the goals CSEPs aimed to achieve. Subsequently, CSEPs were interviewed to collect the motivators to establish and perceived contributions to CM.

Results: Twenty-two CSEPs were identified, of which fourteen were interviewed. Interviewed CSEPs indicated several motivators for establishing; a perceived lack of governmental action, democratic values, and diversity of perspectives in CM, a shortage of equipment and means to help, solidarity to contribute to controlling COVID-19, and differences in views with the government regarding CM Aims. All CSEPs believed to have contributed to policy or society, such as influencing opinions of citizens and persons with decision-making authority, or occasionally altering CM. Moreover, CSEPs encountered obstacles in their attempts to contribute to CM such as not being able to establish contact with authorities, and feeling unheard or undermined during contact. Also, CSEPs indicated that the interplay of political interests complicated their ability to contribute. Conclusions: Overall, CSEPs have fulfilled various roles such as providing ideas, producing equipment and informing. The emergence of CSEPs uncover discrepancies between CM and public views. These insights, together with the identified perceived barriers of CSEPs, can be used to improve the connection between (future) management of pandemics and public priorities and interests.

COVID antibodies in patients treated with immune suppressive drugs after 4 doses of vaccination

Jose Alfonso-Sánchez¹, Luis Lopez-Cerrillo², Paula Julian-Pachés², Andrea Benavides-Hernández², Martina Gimenez-Azagra², José Mayordomo-Sánchez², Isabel Jesús-María², Ignacio Barreira-Hernández², Andrea Agurto-Ramírez², José Martín-Moreno¹

¹Universidad de Valencia, Spain, ²Hospital General Universitario de Valencia, Spain

Introduction: CD20 is a phosphoprotein expressed on the surface of B lymphocytes. Antibody binding to CD20 causes a reduction in the number of CD20+ cells through three mechanisms: antibody-dependent cell-mediated cytotoxicity, complement-mediated cytotoxicity, and induction of B cell apoptosis. Objective: to know the level of covid antibodies produced in immunosuppressed patients with anti-CD20 drugs after their 4 doses of covid-19 vaccine. Material and Methods: A group of patients with autoimmune pathologies was obtained with inclusion criteria (being in conditions of immunosuppression or autoimmune disease, being able to control them for antibodies, knowing their basic characteristics) and exclusion criteria (lost patients). In the end, 447 patients were included. Variables studied Ac of covid (Quant), age in years, sex, drug, treatment time.

Results: In the final analysis of the results, the mean age was 63 years, being somewhat higher in men than in women, and the mean of Ac of covid was 243. In the multiple regression taking the number of antibodies as the dependent variable, the significant variables were: the treatment time coefficient 2.47 (1.5-3.2), and the age of the patients with 1.9 (1.3-2.8). The interactions between the different variables were not significant. Conclusions: The factors that conditioned the level of antibody response in covid-19 vaccination in this type of patient were the time of treatment and age. Keywords: covid vaccination, antibodies, immunosuppression

Perspectives on future of healthcare worker in post-COVID-19 Era: a comparative study of Eastern Europe and Middle Eastern economics concerning healthcare workers

Yousif Khattee¹

¹Azadi Public Hospital, Iraq

The healthcare landscape in many countries around the world has failed to change quickly to respond to the necessities of the COVID-19 pandemic. Meanwhile, the demand for healthcare services during the pandemic has plunged rapidly and government responses were limited to the healthcare system, the human labor in the healthcare system, healthcare infrastructure, and government financial contribution prior COVID-19 and the government preparedness for pandemics. COVID-19 has been a serious challenge for the global markets and for labor in all sectors, however, the healthcare worker have had many difficult and serious challenges including encountering COVID-19 with limited information on this contagious virus, dealing with the infected patients, dealing with their family needs and running hospitals and healthcare centers to assure required healthcare services are delivered properly. For healthcare workers hospitals impose mandatory work at healthcare locations, while for many other organizations and institutions a new trend of working remote or online from home was practiced. The sudden switch to work in hospitals and in COVID-19 centers has created fear even for healthcare workers to expose to the threat directly because when healthcare workers were infected hospitals did not have enough capacity to even take care to their workers. The sample of this study will focus on Eastern European economics while compare them to the Middle Eastern economics, the healthcare workers in both regions as the two case studies will be analyzed. The study is guided by few essential questions are: to what extend healthcare workers got supported to avoid them encounter serious financial difficulties during the COVID-19 pandemic? Compliance to health risk warning in notification of COVID-19 close contacts of exposure and Self-monitoring requirements

Si Chong¹, Benjamin Seah¹, Andrea Lim¹, Xin Chong¹, Peter Law¹, Joan Lee¹

¹Ministry of Health, Singapore

Aim: We aim to describe the overall compliance rates in the electronic acknowledgement of HRW notification receipt and submission of ART results and its contribution to effective pandemic management. Methodology and Results: Based on electronic records held centrally. From 1 Nov 21 to 31 Jan 22, a total of 435,398 Health Risk Warning (HRW) notifications were sent via SMS to close contacts of COVID-19 cases. 95.56% of the intended recipients

acknowledged receipt electronically and 95.04% of the pHRWs submitted ART results electronically. We noted a statistically significant difference between the proportions of those aged <60 years old and those aged ≥60 years, in terms of electronic acknowledgement and ART result submission compliance rates. Discussion: Plausible explanations for the trend observed include a relatively higher proportion of the elderly being non-conversant in the English language or who had a lower level of digital literacy. Those living alone and/or who were socially isolated during the pandemic may have experienced difficulties obtaining assistance in terms of interpreting and responding to these electronic messages. Given the widespread acceptability of SMSs as an electronic means to quickly notify close contacts of all ages, their exposure and prescribed public health actions, we are of the opinion that it is a valuable tool and should be used for future pandemics in populations characterised by a high level of social responsibility and high mobile phone penetration rate. However, particular attention should be paid to individuals aged 81 to 85 years old and in the adjacent age bands as they were noted to be characterised by low acknowledgement and compliance rates, presumably due to lower IT literacy and limited accessibility to electronic devices.

Young people's guide to the COVID galaxy: preferences for COVID-19 research communication

Caitlin Douglass¹, Merryn Roe², Lindi Masson², Felicia Schlotthauer², Zay Swe³, Stephanie Main², Megan Lim², Michelle Raggatt²

¹Burnet Institute, Melbourne, Australia, ²Burnet Institute, Australia, ³Burnet Institute, Burma (Myanmar)

Background and Objective: Research communication is critical for raising awareness of COVID-19 prevention measures and optimising public health responses. However, research is often communicated in ways that exclude participants, including young people. This study aimed to understand young people's preferences for COVID-19 research communication in Australia. **Methods:** In February 2022, we conducted four online Zoom workshops with two groups of young people aged 18-22 years. Workshops went for two hours each and involved activities where participants could contribute ideas through verbal discussion and text, pictures and drawings on a virtual whiteboard. Workshop one focused on building relationships between participants and researchers and developing skills to ask open ended questions. Workshop two explored perceptions of existing research communication. Workshop three explored young people's ideas for communicating COVID-19 research and workshop four involved generating recommendations. Data including transcripts and whiteboard materials, were entered into NVivo and thematically analysed.

Results: Nine young people participated in the workshops (3 female, 3 male and 3 non-binary). Participants expressed the need to communicate research relevant to their experiences, including the challenges they faced throughout the pandemic and their positive contributions to society. Although participants trusted evidence communicated by reputable organisations, they identified an opportunity for young people to collaborate with researchers to produce authentic and relatable content. Young people appreciated when researchers highlighted their most important Findings using clear visuals, animations, infographics and humour. Given the overwhelming amount of COVID-19 information, research needed to be accessible and integrated into platforms young people were already using, such as short videos on TikTok and Instagram.

Conclusions: Findings suggest there are opportunities to make COVID-19 research communication more relevant for young people by incorporating their experiences and ideas. Further studies where researchers partner with young people are needed to develop and test content using social media.

Universidad de Los Andes, Santiago, Chile, ⁷Department of Biology, Faculty of Chemistry and Biology, Universidad de Santiago de Chile, Chile

Background: Households are the high-risk setting for SARS-CoV-2 transmission, especially for close and prolonged person-to-person contact. However, the role of household structural and clinical factors, especially angiotensin-converting enzyme 2 (ACE2), is scarce studied. We analyzed the household SARS-CoV-2 infection during the first and second waves of the COVID-19 outbreak and associated factors in household contacts. **Methods:** We conducted a prospective cohort study of 109 household clusters with a 60-day follow-up (109 index cases and 248 household contacts) in a selected population in Santiago de Chile. Home interviewers measured: compliance with non-pharmaceutical interventions, household structures, symptoms questionnaire; comorbidities and periodontal condition self-report; and saliva samples and nasopharyngeal swabs for ACE2 and SARS-CoV-2 viral load determination. The secondary attack rate (SAR) of SARS-CoV-2 risk factors was assessed using Poisson random-mixed models. Incidence Rate Ratios (IRR) and p-values are reported.

Results: The baseline SAR in household contacts was 0.478 (within household variations of 0.03) and 0.488 at the end of the follow-up. Of infected households, 13.6% of contacts were asymptomatic at baseline 23.7% and 12.7% at 7-day and 14-day follow-up, respectively. Infected household contacts were younger (35.9 y vs. 41.1 y, p=0.02), less hypertensive (9.3% vs. 18.5%, p=0.03), and had lower levels of ACE2 (0.04 ng/dl vs. 0.07 ng/dl, p=0.02) than those uninfected. Factors associated with household transmission were a greater number of adult inhabitants (IRR 0.77, p<0.01) and a greater number of rooms (IRR 0.8, p=.003). **Conclusions:** In our study, during a COVID-19 when index cases were enrolled, more than 48% of their household contacts were already infected. The composition and structure of the home play an essential role in preventing household SARS-CoV-2 transmission. The ACE2 levels may play an important role in household contacts, but further studies are needed.

Hospital hand hygiene after COVID-19: has the pandemic heightened healthcare workers' awareness?

Margherita Zeduri¹, Alice Sgueglia¹, Giacomo Vigezzi¹, Marina Lanave², Rebecca Galvi², Alba Muzzi², Anna Odone¹

¹Department of Public Health, Università degli Studi di Pavia, Pavia, Italy,

²Medical Direction, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Hand hygiene (HH) is the most effective, low-cost measure for preventing transmission of healthcare-associated infections (HAI), and a cornerstone to COVID-19 prevention. Aim of this study is to assess Healthcare Workers' (HCW) adherence to WHO optimal practices, in order to promote a culture of safety and quality infection prevention and control (IPC) activities. Fondazione IRCCS Policlinico San Matteo, Pavia (Italy), implemented a monitoring plan in which HCWs' adherence to HH procedures was evaluated using WHO's 5 moments guidelines, technical manual and observation form. Direct field observations by trained personnel took place from March to October 2022. Process index was HH adherence, stratified by profession, opportunity and unit, with each being inspected at least twice. Overall, 953 HCWs were observed within 18 hospital units (334 physicians, 375 nurses, 190 healthcare assistants, 25 students). Out of 4245 opportunities, global adherence was 52% with 606 handwashings and 1605 handrubblings. The indication with the highest adherence was "after body fluid exposure risk" (69%), whereas the lowest were "before touching a patient" (43%) and "after touching the patient's setting" (44%). Adherence was higher in specialistic surgeries and haematology units, while the worst performances were reported in general surgery ward (33%). Physicians' and nurses' adherence was respectively 46% and 60%. Audits occasionally revealed non-conformities in glove use (i.e., unnecessary use, not changed between patients, hand rubbing on gloves). These findings could be directly linked to habits acquired during the pandemic, when HCWs tended to consider COVID-19 patients as a whole block, to shield themselves from infections. HH awareness has changed in the wake of the pandemic and our study reports how specific initiatives are needed to promote correct HH and optimal practices among HCWs. Therefore, the COVID-19 pandemic reinforced the importance of handwashing and IPC, showing the key role of the HCWs' adherence to HH procedures.

Mitigating the psychological impact of COVID-19 on care givers at Dodoma Municipality, Tanzania

Yohana Mirinde¹

¹Sekoutoure Regional Referral Hospital, University of Dodoma, Mwanza,

Tanzania

Background: COVID-2019 outbreak started at Wuhan city in China, December 2019. On January, 2020 WHO declared it as, public health emergency and upon projection Sub-Saharan Africa was expected to see high number of deaths by 2020, because of poor and limited healthcare systems. In Tanzania by June 2020 there were 509 reported cases and 21 deaths from COVID-19 infection, among all reported cases were in cities. Since COVID-19 pandemic psychological impact was still unclear therefore understanding the psychological burden of the COVID-19 pandemic among caregivers is crucial in guiding policies and interventions to maintain their psychological well-being. **Study Objective** is to assess the psychological impact of COVID -19 on care givers of Dodoma Municipality in Tanzania. **Methods:** A cross-sectional study design were used, random sampling and purposeful sampling for select participants employed. The study established a brief, confidential, self-administered questionnaire containing DASS-21 (Depression, Anxiety, and Stress Scales) designed enquiry, in software data collector (KoBo toolbox), data analyzed by IBM SPSS software version 23.

Results: The current study employed a sample of 246 Dodoma residents' adults caregivers of COVID-19 patients, which found that psychological impact experienced by caregivers were commonly, anxiety, stress and depression was 83.7%, 76.4% 67.5 respectively, and peaking among nurses and family care givers, serving the frontline at hospital and quarantine center of COVID-19 patients. Mitigation of psychological burden, were achieved through taking precautionary measure of COVID-19, clear disease information, psychological support from family member, fellow staff and hospital managements, vaccination and least religious conviction. **Conclusions:** Generally, psychological burden has increased in COVID-19 caregivers, particularly among frontline health care workers, this may increase the risk of mood, sleep and functional disorders, therefore early psychotherapeutic interventions targeting this vulnerable group may be beneficial.

Caring for Long COVID patients in primary health care: a cross-sectional study among general practitioners in Belgium and Malta

Sarah Moreels¹, Sarah Cuschieri², Sherihane Bensemmam³, Robrecht Schreye³

¹Epidemiology and Public Health, Sciensano, Brussels, Belgium, ²Department of Anatomy, Faculty of Medicine and Surgery, University of Malta, Msida, Malta, ³Epidemiology and Public Health- Sciensano, Brussels, Belgium

Background and Objective: At least 10% of COVID-19 recovered individuals experience persistent symptoms (Long COVID), with primary health care and general practitioners (GPs) at forefront in their care. In this study, GPs' knowledge, perception and experience on Long COVID, and the definition used across two countries are investigated to provide insight in their care at cross-country level. **Methods:** A cross-sectional study targeting GPs was conducted in Belgium and Malta during mid-2022. An online survey on Long COVID was disseminated. Country-specific practice and demographic characteristics were collected. Descriptive and logistic regression analyses were performed.

Results: A total of 150 GPs (Belgium=105; Malta=45) responded. Female GPs represented 58.0%, median age was 49 years (IQR: 37-61). In both countries, two in three GPs felt that Long COVID patients were not well followed up by primary care. Most GPs reported insufficient scientific knowledge and information on Long COVID diagnosis and treatment. Accessibility to educational material was limited and an awareness-raising campaign is merited, especially in Malta (OR=6.81, 95%CI [1.49;31.12]). For diagnosing Long COVID, 54.7% reported the requirement of a positive COVID-19 test, especially among Belgian than Maltese GPs (64.3% vs 45.2%, p=0.036). To assess Long COVID, GPs mainly implemented diagnostic criteria by themselves (47.3%) together with persistence of symptoms (4 weeks to 5 months). 76.0% GPs reported caring for Long COVID patients, irrespective of practice type and GPs' country, sex or age (p=0.353; p=0.241; p=0.194; p=0.058). 48.3% of GPs reported to follow-up these patients by themselves or GP colleagues and 29.8% by multidisciplinary cooperation.

Conclusions: At cross-country level, most GPs provide similar (multidisciplinary) care to Long COVID patients. Although GPs perceive lack of scientific knowledge and training on Long COVID, similar diagnostic criteria were noted. Uniform guidelines, scientific support and training for GPs across Europe is a priority to augment their Long COVID approach.

DOI: 10.18332/popmed/165193

COVID-19 pandemic on public health systems and practice in 3 districts from the perspective of public health leaders: a qualitative study in Uganda

Nalwoga Aminah¹

¹Joint Clinical Research Center, Save A Life Foundation, Kampala, Uganda

The COVID-19 pandemic has impacted health systems worldwide. Studies to date have largely focused on the health care system with less attention to the impact on public health systems and practice.

Objective: To describe the early impacts of COVID-19 on public health systems and practice in 3 Ugandan districts from the perspective of public health system leaders and synthesize lessons learned.

Design: A qualitative study using semi structured virtual interviews with public health leaders between October 2020 and April 2021. The World Health Organizations essential public health operations framework guided data collection and analysis.

Setting: This study involved the Ugandan government. These districts were chosen for their large populations, relatively high COVID-19 burden, and variation in public health systems.

Participants: Public health leaders from Kampala (n = 21), Wakiso (n = 18), and Mubende (n = 19) in organizations with a primary mandate of stewardship and/or administration of essential public health operations (total n = 58).

Results: We found that the COVID-19 pandemic led to intensified collaboration in public health systems and a change in workforce capacity to respond to the pandemic. This came with opportunities but also challenges of burnout and disruption of non-COVID-19 services. Information systems and digital technologies were increasingly used and there was greater proximity between public health leaders and other health system leaders. A renewed recognition for public health work was also highlighted.

Conclusions: The COVID-19 pandemic impacted several aspects of public health systems in the provinces studied. Our findings can help public health leaders and policy makers identify areas for further investment (eg, intersectoral collaboration, information systems) and develop plans to address challenges (eg, disrupted services, workforce burnout) that have surfaced.

Impact of COVID-19 vaccination on mortality from COVID-19 severe acute respiratory syndrome (SRAG-COVID) in Brazilian municipalities in 2021

Rômulo Paes-Sousa¹, Gabriela Silva², Mônica Castro², Anelise Souza³, Gustavo Fernandes⁴

¹Brazil, ²René Rachou Institute, Oswaldo Cruz Foundation, Brazil, ³Federal University of Ouro Preto, Brazil, ⁴Fiocruz, Brazil

Background and Objective: During the COVID-19 pandemic, Brazil had difficulties in carrying out a timely vaccination campaign throughout its territory, already marked by strong social and health inequalities. The combination of vaccination of delay and structural inequality produced a heterogeneous vaccine coverage across the country. This work Aims to evaluate the differences in the impact of COVID-19 vaccination by on mortality due to COVID-19 severe acute respiratory syndrome (SRAG-COVID) in the country municipalities. In 2022, the initial difficulties on providing adequate vaccination coverage were overpassed.

Methods: Ecological study from January to December 2021, with monthly data from 200 Brazilian municipalities in five Brazilian regions with at least 25 deaths from COVID-19 in January 2021. A linear regression model was performed for the country and regions, with log-log transformation and fixed effects in the municipality, using SARS-COVID mortality rate standardized by age and sex as the dependent variable, first dose coverage as the independent variable and a significance level of 5%.

Results: The monthly average standardized mortality rate in January 2021 was 33.1 deaths/100,000 inhabitants, being higher in municipalities in the North and Midwest regions. Vaccination started in January 2021 and reached an average first dose coverage of 74.5% in December 2021, when the average mortality rate was 2.2 deaths/100,000 inhabitants, fifteen times lower than January 2021. A 10% increase in vaccination coverage caused an average decrease of 5.6% in the municipalities monthly mortality rate, with a significant effect in all regions, greater in the North (8.7%) and Northeast (6.3%).

Conclusions: Also in Brazil, vaccination was crucial for reducing deaths from COVID-19 and had a greater effect in the poorest regions of Brazil. A homogeneous increase in vaccination coverage, with a timely and well-articulated campaign by the central government, could be an important tool for reducing the country's territorial inequalities.

Knowledge, attitudes, practices and perceptions around SARS

CoV rapid antigen self-tests among urban poor communities of Mohammadpur and Bangalore, India

Neha Parikh¹, Syama Syam¹, Ravneet Kaur¹, Angela Chaudhuri¹, Shankar A.G.¹

¹Swasti Health Catalyst, India

Background and Objectives: Urban poor are low-income, marginalized communities, particularly at risk of infectious diseases. COVID-19 exposed them to a range of problems that hindered access and utilization of health services perpetuating poor health outcomes and increased transmission. The knowledge and uptake of community-based-testing in vulnerable communities remains difficult, even in long prevailing conditions like HIV, more so for covid-19. Testing alone is insufficient unless it is integrated with the continuum of primary care. Although self-tests are approved for individual use, the feasibility, and acceptability of tests for the disadvantaged remains unclear. This study is aimed to determine the feasibility and acceptability of sars-cov-2 self-testing using a health worker-assisted model among 2 urban slums in India.

Methods: A mixed methods study is being conducted (aug- dec 2022) among urban poor in Mohammadpur and Bangalore, where health worker assisted self testing is introduced as part of an ongoing community intervention that provides comprehensive healthcare services.

Results: Preliminary findings indicate limited knowledge about self tests in urban poor. Reported uptake of tests was poor at 15%, with reasons of apprehension ranging from ability to complete tests, concerns about results and potential stigma from communities. Self reported willingness to undergo self-testing was high at 91%. Around 77% participants preferred some sort of assistance for conducting the self tests preferring tests to be conducted at existing community institutions. The next round of this study will measure the change in capacities and acceptability of the study at the endline.

Conclusions: Conventional covid-19-rtPCR testing presents a huge barrier for urban poor in terms of costs, access, loss of livelihood and stigma. Self tests are empowering, allowing vulnerable individuals control over their health. Results from this intervention will provide learnings for implementation and scale of self-tests bringing relevant findings for point-of-care devices and enable health system preparedness.

COVID-19 vaccine hesitancy in Western Balkans

Sanja Matovic-Miljanovic¹, Smiljana Cvjetkovic², Vida Stojkovic², Stefan Mandic-Rajcevic^{3,4}, Janko Jankovic^{3,4}, Michele Gross⁵

¹Euro Health Group A/S, Søborg, Denmark, ²Department of Humanities, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, ³Institute of Social Medicine, Belgrade, Serbia, ⁴Faculty of Medicine, University of Belgrade, Belgrade, Serbia, ⁵Public Health, Euro Health Group A/S, Søborg, Denmark

Background and Objectives: The uptake of COVID-19 vaccines in Western Balkan countries is lagging far behind the European Union average, with vaccine hesitancy as a serious threat and reason for the insufficient vaccination coverage and suboptimal herd immunity. Understanding factors that influence vaccine uptake in those countries is critical for development of effective vaccination promotion strategies for Western Balkans.

Methods: Cross-sectional research was carried out from July to October 2021. Convenience sampling included 1605 individuals aged 18 and above from Albania, Bosnia and Herzegovina, North Macedonia, Montenegro and Serbia. Online questionnaire was shared through social media.

Results: In all countries both vaccinated and unvaccinated respondents consider the vaccine against COVID-19 to be more safe than effective. The most positive attitudes towards COVID-19 vaccine safety are found in North Macedonia (M=3.61, SD=1.17) and Serbia (M=3.50, SD=1.26). Around 40% of respondents believe that pharmaceutical companies are reluctant to publish research reports on risks of adverse reactions to vaccines. Over 70% respondents in Albania and North Macedonia and 66.5% in Montenegro and Bosnia see important role for primary health physicians in educating people on importance of vaccination and consider them as trusted sources of information about COVID-19. Women and those with higher education (Bosnia and Herzegovina, Montenegro and Serbia) manifest a more pronounced personal sense of social responsibility in achieving collective immunity. Respondents who assessed themselves as more religious consider vaccine against COVID-19 as less safe and effective, demonstrate less trust towards societal factors and are less likely to demonstrate social responsibility in the context of vaccine behaviour.

Conclusions: Family physicians should have a key role in promoting vaccination and educating public in Western Balkans. Partnerships with representatives of

religious groups and awareness campaigns with focus on young people should be the core of public health interventions addressing vaccine hesitancy in Western Balkans.

Analysis of the preparedness for the COVID-19 pandemic in the rural areas of the Bolivian Chaco

Daria Bucci¹, Vieri Lastrucci^{2,3}, Francesco Cosmi⁴, Carlo Signorelli^{5,1}, Maria Caldés⁶

¹School of Medicine, Vita-Salute San Raffaele University, Milan, Italy,

²Department of Health Science, University of Florence, Italy, ³Epidemiology Unit, Meyer Children's University Hospital, Florence, Italy, ⁴Convenio de Salud, Camiri, Bolivia, ⁵IRCCS San Raffaele Hospital, Milan, Italy, ⁶Centro di Salute Globale of Tuscany Region, Meyer Children's University Hospital, Florence, Italy

Public health emergency preparedness is essential to mitigate pandemics effects, especially in low-resource contexts. This retrospective analysis evaluates planning and response capacities, available resources, and care management, among indigenous communities living in rural areas of the Gran Chaco Region of Santa Cruz Department, Bolivia, during the first wave of the COVID-19 pandemic. Authors derived and pooled original data from local databases on positive cases, deaths, tests executed, and vaccination registers. The population was administered two surveys by convenience sampling of healthcare facilities of rural communities insisting in four municipalities of the Province and to heads of communities, accordingly. Data collection period was from May 2022 to June 2022. The first COVID-19 case in the area was recorded on April 17, 2020, and the maximum peak of daily records during the first wave was 113 cases in September 2020. A total of 39 healthcare facilities were surveyed, insisting in 117 communities. Data from the healthcare facilities survey showed that 50% were prepared for the pandemic. Although approximately 85% of the pooled received information from the MoH on the contact tracing methodology, 65% received practical guidance on the clinical management of patients. 58% of the facilities arranged temporary beds, 71% in different locations (e.g. schools). Most facilities were supplied with equipment such as pulse-oximeters (79%), oxygen cylinders (75%), and antibiotics (63%). Only eight per cent of respondents stated the equipment was present before the pandemic began, while 46% received it afterward. 69% of respondents reported unpreparedness for the following wave. Rural communities of the Chaco were largely unprepared and suffering from pre-existing resource challenges for communities' care. Although the first wave arrived six months later than the rest of the world, half of the responders reported an adequate preparedness level, and public policies did not address the region with appropriate interventions.

DOI: 10.18332/popmed/165266

Involving cases and contacts more actively and autonomously in contact tracing through digital tools: a mixed methods investigation among Dutch public health professionals involved in COVID-19 contact tracing

Yannick Helms¹, Mart Stein², Nora Hamdiui¹, Akke Meer¹, Ruth Baron¹, Renske Eilers¹, José Ferreira¹, Rik Crutzen³, Aura Timen^{4,5}, Mirjam Kretzschmar^{6,7}

¹National Institute for Public Health and the Environment (RIVM), The Netherlands, ²National Institute for Public Health and the Environment (RIVM), Netherlands, ³Maastricht University/CAPHRI, The Netherlands, ⁴Radboud University Medical Centre, The Netherlands, ⁵Radboud University, The Netherlands, ⁶Utrecht University Medical Centre, The Netherlands, ⁷Julius Center for Health Sciences and Primary Care, The Netherlands

Background and Objective: Contact tracing (CT) can be an effective tool to prevent transmission of communicable diseases. However, public health services may not always have sufficient human resources at their disposal to facilitate CT adequately. In the EU-project 'CORESMA', we investigated if and how this may be compensated by involving cases and contacts more actively and autonomously in the identification, notification, and monitoring of contacts through digital tools, from the perspective of Dutch public health professionals (PHPs).

Methods: Between November 2020 and April 2022, we conducted interviews (N=17) and distributed an online questionnaire (N=637) among PHPs involved in CT for COVID-19 in the Netherlands. An inductive thematic analysis of the interviews was performed to identify barriers/facilitators influencing PHPs' intention to involve cases and contacts in CT through digital tools. Random forest analyses of the questionnaire data were performed to prioritize the qualitatively identified barriers/facilitators to inform the future development and implementation of

digital tools.

Results: Interviewees were generally open towards more actively and autonomously involving cases and contacts in CT for COVID-19 through digital tools. Most questionnaire respondents had a positive intention to use digital tools for the identification (66.1%), notification (58.6%), and monitoring (55.1%) of contacts. Random forest models accurately predicted the (positive or neutral/negative) intention of 80-82% of questionnaire respondents to use digital tools for the identification, notification, and monitoring of contacts, respectively. Accelerating the CT-process, reducing PHPs' workload, and sufficient support for cases and contacts were the top predictors of PHPs' intention.

Conclusions: Most PHPs are open towards involving cases and contacts through digital tools. Based on our Results, we created a 'blueprint' for the development and implementation of digital tools in CT. In a small-scale randomized pilot study, we are currently comparing different digital methods to let cases autonomously identify and notify their contacts.

Impact of the COVID-19 pandemic on stroke and ST-segment elevation myocardial infarction patient management: French regional registry

Florence Francis¹, Emilie Lesaine^{2,3}, Sandrine Domecq⁴, Laura Cetran⁵, Pierre Coste⁵, Sahal Hadi¹, Catherine Pradeau⁶, Francois Rouanet⁷, Floriane Sevin⁸, Igor Sibon⁷, Florence Saillour-Glénisson⁹

¹CHU de Bordeaux, France, ²Bordeaux Population Health, University of Bordeaux, Bordeaux, France, ³Centre Hospitalier Universitaire (CHU) de Bordeaux, Bordeaux, France, ⁴CHU de Bordeaux, ⁵Coronary Care Unit, Hôpital Cardiologique, CHU de Bordeaux, Nouvelle-Aquitaine, France, ⁶Pôle de médecine d'urgence, CHU de Bordeaux, Bordeaux, France, ⁷Stroke Unit, Department of Neurology, CHU de Bordeaux, France, ⁸Bordeaux Population Health, CHU de Bordeaux, University of Bordeaux, Bordeaux, France, ⁹CHU de Bordeaux, Pôle de santé publique, Service d'Information Médicale, Bordeaux Population Health, University of Bordeaux, ISPED, Centre INSERM U1219, Bordeaux, France

Background and Objective: Around the world, the consequences of the COVID-19 pandemic on the management of no-COVID-19 pathologies are causing concerns. We aimed to assess the impact of changes in use of care and health reorganizations implementation spurred by the COVID-19 pandemic (first wave), on acute management times of strokes and ST-segment elevation myocardial infarctions (STEMI).

Methods: The study was based on two cohorts of stroke and STEMI patients included between January 2019 and August 2020 in a French regional registry. The hospital reorganizations were systematically collected from heads of hospital departments. The associations between reorganizations, use of care, and care management times were analyzed through multivariate linear regression mixed models. Interaction terms between the use of care variables and the period (pre, per, post-wave) were introduced.

Results: A total of 9,218 patients were included (6,436 stroke and 2,782 STEMI patients). Per-wave period management times deteriorated for stroke but maintained for STEMI. Per-wave changes in use of care did not have any impact on STEMI management. No association was found between reorganizations and stroke management times. In the STEMI cohort, the implementation of a systematic testing at admission was associated with an increase of 41% in care management times (exp=1.409, 95%CI [1.075-1.848], p=0.013); the implementation of the global "plan blanc", concentrating resources in emergency activities, was associated with a decrease of 19% in management times (exp=0.801, 95%CI [0.639-1.023], p=0.077).

Conclusions: The pandemic induced no deep altering of emergency pathway structuration. The better resilience of the STEMI pathway than the stroke one is interpreted as linked with its stronger structuration. Transversal reorganizations aiming at concentrate resources on emergency care contributed to maintaining quality of care.

DOI: 10.18332/popmed/165293

Innovative shortcuts and initiatives in Primary Health Care for rural/remote localities: a scoping review on how to overcome the COVID-19 pandemic

Renata Siqueira¹, Aylene Bousquat², Simone Schenkman³, Amandia Sousa⁴

¹Institute for Collective Health, University of Sao Paulo - USP, Brazil, ²University of Sao Paulo, Sao Paulo, Brazil, ³University of Sao Paulo (USP), Brazil, ⁴FIOCRUZ Amazonia, Brazil

Background and Objective: The COVID-19 pandemic has emerged as one of the greatest challenges to societies and to world health systems in the last century. Therefore, it is essential to discuss the role and initiatives of Primary Health Care (PHC) to deal with it. Regarding the response to the pandemic, the rural/remote PHC context in the pandemic is barely visible. This review aims to analyze the set of individual and collective initiatives and innovations developed to face the pandemic, within the PHC scope, in rural/remote areas.

Methods: A scoping review methodology was applied to peer-reviewed articles. Eight databases were searched to identify studies published from January 2020 to July 2021. The main focus sought in the literature was the set of initiatives and innovations within the PHC scope in rural/remote locations during the pandemic. The bibliographic information was imported into a web application for systematic reviews, following the scoping review stages.

Results: This review included 38 studies, mostly from Australia, Canada, USA and India. The main PHC initiatives were related to access; to the role of Community Health Workers and Health Surveillance; and to the importance of placing and retaining human resources in health. Cultural, equity and vulnerability issues occupy an important place among the initiatives. Regarding the innovations, telecare and customized communication are highlighted. From an organizational dimension, these locations showed flexibility to deal with the pandemic and it is important to indicate that they have potential for intersectoral activities at the local level.

Conclusions: The findings summarize initiatives and innovations developed to face the pandemic, within the PHC scope in rural and remote areas. This review has identified collective, clinical, intersectoral and organizational health initiatives. An articulation between different government levels would be paramount in evaluating the implementation of policies in these areas for future epidemics.

DOI: 10.18332/popmed/165306

Micronesian community response to COVID-19

Strue Wakuk¹, Jendrik Paul²

¹Institute for Collective Health, University of Hawaii Cancer Center, United States, ²Department of Health, Missouri Coalition for Oral Health (MCOH), United States

Background and Objective: The beginning of 2020 in Hawaii symbolized a time consumed with fear, despair, and confusion. Micronesians, historically excluded in Hawaii, often experienced discrimination and stigmatization. This population vastly emerged, with a population size of 18504 from 2013 to 2017, approximately 1.3% of the state population. Unfortunately, the influx migration of Micronesians pressured the state economy. Many have depended on government assistance, especially during the transiting time. In 2017, Hawaii's spending on COFA migrants was \$363 million. Due to Hawaii's high cost of living, most Micronesians live together to make ends meet. When COVID hit, Micronesians suffered, but with resiliency fabricated in their cultural heritage, they persevered through racism and hardships associated with COVID.

Methods: The resiliency of the Micronesian community was obvious with the robust planning and implementations throughout COVID. There are two grassroots that emerged in response to the needs of the people. Some performances were executed to help the communities through food distribution, supplies distribution, and other COVID-19 assistance—Micronesian champions engaged in different entities tackling COVID challenges to alleviate their communities. Leaders were out in the community, raising awareness about COVID and the vaccine.

Results: The resilience of Micronesians is obvious in withstanding challenges against racism, language barriers, healthcare, and COVID. Micronesians persevered above and beyond societal expectations. The number of cases and vaccinated participants can prove the hard work of the community. The latest report on COVID cases stated that about 54 patients were diagnosed in August 2022 and significantly dropped to 19 in November 2022. The COVID mortality rate reported in August was one person and none in November.

Conclusions: In conclusions, the robustness and resilience of this community in tackling COVID-19 should be highlighted and used for a future roadmap to guide the community in any health crisis.

Socioeconomic inequalities in times of COVID-19 lockdown: prevalence and related-differences in measures of anxiety and stress in Palestine

Hamzeh Zabadi¹, Maryam Haj-Yahya², Noor Yaseen², Thair Alhroub²

¹Public Health Department, Faculty of Medicine and Health Sciences, An-Najah National University, Occupied Palestinian Territory, ²Department

of Medicine, Faculty of Medicine and Health Sciences, An-Najah National University, Nablus, Occupied Palestinian Territory

Background: Implementation of quarantine and lockdown to COVID-19 pandemic has created dramatic negative psychological impact mainly the general populations health worldwide. We aimed to assess the prevalence and predictors of anxiety and stress severity among the Palestinian population.

Methods: A cross-sectional web-based survey was conducted. An anonymous online questionnaire and snowball recruiting technique were used to target the general public in Palestine between 6 and 16 April, 2020 during COVID-19 pandemic lockdowns. Multivariate logistic regression models were developed for the outcome variables.

Results: Of the 2819 individuals who completed the questionnaire, more than two thirds of them (72.6%) were females. Nearly (83.5%), were residing at the West Bank. The mean age of participants was 29.47 (SD = 10.97) years. The anxiety prevalence was (25.15%) with (20.08%) had mild/moderate severity. The stress prevalence was (38.77%) with (22.21%) had mild/moderate severity. The prevalence of both anxiety and stress was (20.3%). In multivariate analysis, exposure to confirmed case of COVID-19, inadequacy of food supply and jobs that acquire leaving home during lockdown were significantly related to higher anxiety degree. As for stress, low monthly income, cohabitation with a person of a high-risk group and inadequacy of food supply were significantly related to higher stress degree.

Conclusions: Young adults with low socioeconomic status and inadequate food supply were more likely to have a higher degree of stress and/or anxiety. Providing alternative economical sources for those in need, and spreading more awareness regarding the pandemic, supporting the populations psychological wellbeing, community connection and the availability of specialist mental health services are crucial to overcome the mental impacts of COVID-19 in Palestine.

COVID-19 preventive behaviors and information sources: a cross-sectional study in Japan

Manae Uchibori¹

¹Keio University, Japan

Background and Objective: Individual preventive behaviours are one of the key ways needed to prevent the spread of COVID-19. The objective of this study was to identify the factors associated with the adoption of COVID-19 preventive behaviors, focusing on use and trust of information sources about covid-19.

Methods: A nationally representative cross-sectional survey of 30053 Japanese adults was conducted in February 2021. We estimated the associations between the adoption of COVID-19 preventive measures and a broad array of individual factors. A total of three multivariable logistic regression models was constructed to identify the factors associated with the adoption of each of three preventive measures: 3cs avoidance ("closed spaces", "crowded places", and "close-contact settings"), hand hygiene and respiratory hygiene.

Results: The prevalence of preventive behaviours was 35.92% for 3cs avoidance, 80.43% for hand hygiene and 67.66% for respiratory hygiene. After adjusting for covariates, socioeconomic variables, psychological variables, and the use and trust of information sources were statistically significantly associated with the adoption of three preventive measures. Trust in social media was associated with lower odds (0.91, confidence intervals 0.86-0.96), while trust in healthcare professionals was associated with higher odds (1.10, 1.05-1.16). The number of information sources used and the odds of adopting 3cs avoidance were positively associated, e.g. An odds ratio of 2.70 (2.48-2.94) for five or more sources in reference to one source. In addition, the greater the number of social media used as an information source, the higher the odds of avoiding the 3cs, e.g., an odds ratio of 4.55 (2.03-10.19) for six or more sources in reference to none. Similar trends were observed for hand hygiene and respiratory hygiene. **Conclusions:** The findings indicate that access to multiple sources of information and social networks to provide public health messages may be important in promoting prevention measures for COVID-19.

What the COVID-19 pandemic teaches us about modeling epidemics?

Jean-François Mathiot¹, Laurent Gerbaud², Vincent Breton³

¹Laboratoire de Physique de Clermont, Centre national de la recherche scientifique (CNRS), France, ²CHU Clermont-Ferrand, Clermont-Auvergne University, France, ³Laboratoire de Physique de Clermont, Centre National de la Recherche Scientifique (CNRS), France

Background and Objective: The COVID19 pandemic associates a continuous diffusion at low intensity, with a majority of patients with poor clinical signs, and rapid accelerations with the combination of super spreading patients and situations, with high rates of severe cases. The nature and intensity of social relationships play a central role to predict its evolution. To better take into account the role of these relationships, we built a model based on percolation theory, and showed that it was a good predictor of the incidence of hospitalization. In this work, we compare our model, called PERCOVID, to the SEIR (Suspected, Exposed, Infected, Recovered) model considered as the reference for modeling epidemics. **Methods:** Time study was divided in five periods which played a major role in the propagation of the pandemic in France: initial underground propagation (December 2019 / January 2020), first wave and first lockdown (February / March 2020), first summer after lockdown (June / August 2020), spread of alpha variant (March / May 2021), decline of vaccine efficiency (October / November 2021). For each period, we shall compare the results of the PERCOVID and SEIR models for the same epidemiological and sociological parameters, emphasizing the role of local spread of the epidemic as compared to long-range contamination.

Results: In the periods of underground propagation and acceleration of the virus or its variants, SEIR type predictions largely overestimate the incidence rate as compared to predictions from PERCOVID. Both models perform similarly in the period of epidemic slowdowns, particularly when the mobility of the population is important. **Conclusions:** PERCOVID is a powerful tool in order to disentangle the intrinsic properties of the virus, like its infectiousness, from the nature of social relationships in the population under study and from the influence of any regulation issued by national authorities.

The impact of Long COVID Syndrome treatment and rehabilitation: systematic review and meta-analysis of patient-reported outcomes

Gianfranco Damiani¹, Domenico Pascucci², Mario Nurchis², Gerardo Altamura², Gian Raspolini², Aurora Alizadeh², Giuseppe Santoli², Giulio Pasca²

¹Institute for Collective Health, Università Cattolica del Sacro Cuore, Italy,

²Università Cattolica del Sacro Cuore, Italy

Background and Objective: COVID-19 pandemic resulted in an unprecedented public health crisis, in which efforts mostly focused on containment and treatment of acute disease. However, important disease sequelae are increasingly reported by clinicians and addressed in terms of treatment and rehabilitation needs. The long COVID syndrome (or post-COVID-19 condition) is a still poorly investigated condition, which makes the patients' subjective evaluation of symptoms via Patient-Reported Outcome Measures (PROMs) vital. The aim is to evaluate treatment and rehabilitation interventions for long COVID management, through PROMs.

Methods: A systematic review was performed querying Medline, Scopus and WebOfScience databases, according to the following inclusion criteria: evidence involving patients of all age groups diagnosed with long COVID syndrome, undergoing several physical and/or psychological interventions, and using PROMs to collect patients' feedback. For each type of intervention meta-analyses were computed adopting the Paule-Mandel random-effects model, while T-tests were performed to investigate differences in efficacy between rehabilitation and treatment. All statistical analyses were conducted using statistical software STATA.

Results: Out of 481 papers retrieved, 16 met the inclusion criteria. Most frequently used PROMs were Euro-QL-5D, Hospital Anxiety and Depression Scale, and Perceived Stress Scale. Efficacy of physical interventions (SMD 0.29 95% CI 0.12–0.51), psychological ones (SMD 0.17 95% CI 0.05–0.36) and both (SMD 0.35 95% CI 0.18–0.71) was consistently proved. Evidence supported the efficacy of online-delivered interventions for all the categories; no statistical differences were found regarding the positive impact of both rehabilitation and treatment for all interventions (p>0.05).

Conclusions: There is promising evidence regarding Long COVID treatment and rehabilitation impact on patients' quality of life and general well-being. This paper partially fills a literature gap on an actual and potentially persistent public health matter regarding the chronic consequences of the COVID-19 pandemic, although further studies are needed.

Achieving COVID-19 vaccination equity in South Eastern Metropolitan Victoria, Australia

Evelyn Wong^{1,2}, Brett Sutton³, Mohana Baptista¹, Catherine McGrath¹, Tom McLaughlin¹, Andrew Stripp⁴, Rhonda Stuart⁴
¹Monash Health, Clayton, Australia, ²Monash University, Clayton, Australia, ³Victorian Department of Health, Melbourne, Australia, ⁴Monash Health, Victoria, Australia

Background: This study aimed to describe COVID-19 vaccination uptake across Local Government Areas (LGAs) in Victoria using the South East Public Health Unit (SEPHU) catchment as a case study, and to explore key policy and implementation strategies that contributed to equitable uptake. There were significant socioeconomic disparities between LGAs within the SEPHU catchment, ranging from the most advantaged, Bayside, to the most disadvantaged, Greater Dandenong, where over 60% of the population were born overseas and spoke a language other than English.

Methods: Using an ecological study design, we compared trends in COVID-19 vaccination first and second dose uptake in Victoria and reviewed key social and public health measures used in Victoria's and SEPHU's vaccination program rollout from 1st January to 31st December 2021.

Results: By July 2021, half of the adult population in Bayside, had received their first vaccination dose compared to only a quarter in Greater Dandenong. However, by 31st December 2021, this geographical variation was narrowed to 1.3% for first dose (95.6% in Bayside and 94.3% in Greater Dandenong) and 2.5% for second dose (94.9% in Bayside and 92.4% in Greater Dandenong), a trend that was also observed broadly across Victoria. Key Victorian policy changes from September 2021 included vaccination mandates for essential workers and later for staff and patrons in hospitality and entertainment venues. Key engagement and vaccination strategies employed by SEPHU included strong engagement and co-designing programs with community leaders, mass vaccination centres, community outreach clinics, a mobile vaccination bus, and a highly visible walk-in vaccination pop-up at a shopping centre.

Conclusions: There were multiple policy and implementation factors contributing to the successful narrowing of COVID-19 vaccination inequities in Victoria. Deeper causal analysis is needed to investigate the individual impacts of these factors which can inform strategies to achieve similar success in future mass vaccination programs.

Predicting death for nursing home residents before and after COVID-19 vaccination: can we prevent the next pandemic?

Komal Aryal¹

¹McMaster University, Hamilton, Canada

Introduction: COVID-19 vaccinations have reduced COVID-19 cases and mortality for nursing home (NH) residents. However, little is known about how the discriminability of COVID-19 death changed before and after vaccination. The objective of this study is to examine factors that predict COVID-19 death before and after vaccination.

Methods: We conducted a retrospective cohort study on NH resident data collected using the Resident Assessment Instrument Minimum Data Set Version 2.0. The cohort included 14977 residents who tested positive for COVID-19 between March 7, 2020, and July 31, 2021. The cohort was split into two groups, COVID-19 deaths before and after January 1st, 2021. Logistic regression, LASSO regression, and random forests methods were used to evaluate the predictive ability of resident characteristics and COVID-19 mortality. Model performance was assessed using the area under the receiver operating characteristics curve (AUC). Variable importance was measured by the change in AUC.

Results: Age, sex, diabetes, declining cognition, and deteriorating activities of daily living were the most informative predictors for COVID-19 mortality before and after COVID-19 vaccination. COPD, emphysema, asthma, and emphysema were informative of COVID-19 mortality after vaccination only. The logistic regression, the LASSO regression, and the random forest model display similar predictive ability for COVID-19 mortality in their respective cohorts. A similar discrimination was reached for COVID-19 mortality before and after vaccination (AUC = 0.67, AUC=0.68, and AUC=0.644 respectively).

Conclusions: The factors associated with COVID-19 mortality are multifactorial and may be modifiable. Closer attention to these factors may help reduce COVID-19 mortality. Although the discriminability of the models was poor, advanced knowledge of NH resident characteristics can support upstream decision-making to prioritize care for NH residents who are at the greatest risk of COVID-19 death. Future studies are required to validate these Findings and demonstrate the utility of this model in pandemic preventability.

A rapid global review of guidance to prevent and control COVID-19 in custodial settings

Lindsay Pearce¹, Stuart Kinner², Alaina Vaisey³, Claire Keen³, Lucas Calais-Ferreira³, James Foulds⁴, Ruth Gray⁵, Sunita Sturup-Toft⁶

¹Curtin University, Bentley, Australia, ²Curtin University, Australia, ³University of Melbourne, Australia, ⁴University of Otago, New Zealand, ⁵South Eastern Health and Social Care Trust, Ireland, ⁶Public Health England, United Kingdom

Background and Objective: With over 11 million people incarcerated globally, the prevention and control of COVID-19 in custodial settings is a critical component of the public health response. We sought to identify, collate, and summarise guidance for the prevention and control of COVID-19 in custodial settings in the first six months of 2020.

Methods: We conducted a systematic search of peer-reviewed and grey literature, and manually searched relevant websites to identify publications up to 30 June 2020 outlining recommendations to prevent and/or control COVID-19 in custodial settings. We inductively developed a coding framework and assessed recommendations using conventional content analysis.

Results: We found 201 eligible publications containing 372 unique recommendations across 19 domains that represented key components of a comprehensive COVID-19 response in custodial settings to protect the health of people in prison and the general public. These included: preparedness; physical environments; case identification, screening, and management; communication; external access and visitation; psychological and emotional support; recreation, legal, and health service adaptation; decarceration; release and community reintegration; workforce logistics; surveillance and information sharing; independent monitoring; compensatory measures; lifting control measures; evaluation; and key populations/settings. We identified twelve guiding principles, few conflicting recommendations, and several areas where more guidance was needed.

Conclusions: The breadth of recommendations identified in this review reflects the complexity of COVID-19 response in custodial settings. Despite the availability of comprehensive guidance overall, no one guidance document covered all 19 domains. Important gaps remain in the implementation of recommended prevention and control measures globally and in the availability of evidence assessing their effectiveness on reducing COVID-19 disease, their mental and physical health impacts on inmates and staff, and implementation. Addressing these knowledge gaps are critical to ensure a more effective and humane response to infectious diseases in custodial settings in the future.

The effect of health literacy on delayed COVID-19 vaccine: a cross-sectional study in Hong Kong

Yue Tian¹, Eliza Wong¹, Phoenix Mo¹, Dong Dong¹, Annie Cheung¹

¹Jockey Club School of Public Health and Primary Care, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, China

Background and Objective: Health literacy (HL) is an important determinant of health outcomes, as it determines individuals' abilities to process and use health-related information. However, the association between HL and vaccine delay remains unclear. This study aimed to assess how HL affected the delayed COVID-19 vaccination among Hong Kong adults.

Methods: A cross-sectional study using Quota sampling was conducted. Self-administrated online questionnaires were distributed to a web panel. Multivariable logistic regression models were used to explore associations among three domains (i.e., functional, interactive, and critical) of HL and vaccine delay while adjusting for social demographic and health-related characteristics. Sensitivity analyses were performed to ensure the robustness of the Results.

Results: A total of 401 participants were recruited between August to September 2022. Over half (52%) of the participants have inadequate HL. The proportion of participants with delayed first and third doses of COVID-19 vaccination is 30.9% and 28.2%, respectively. In multivariable analysis, the risk of delaying the first dose was higher among participants with inadequate functional HL (OR = 0.58, p = 0.015) and adequate levels of two subdomains of critical HL (OR = 1.82, p = 0.013; OR = 1.91, p < 0.01). Participants who delayed their third doses were likely to have inadequate interactive HL (OR = 0.52, p = 0.014) and an adequate level of one subdomain of critical HL (OR = 1.71, p = 0.039). The sensitivity analyses confirmed these findings.

Conclusions: Functional and interactive HL were positively associated with COVID-19 vaccination. However, a negative association between critical HL and vaccination was reported. These findings indicate a challenge for health partitioners to promote vaccination campaigns to the public, especially those

with low functional and interactive HL and high critical HL. Researchers and policymakers may need to monitor and report HL when they study vaccination decision behaviours.

Geographical intelligence applied to public health: the examples of Rio de Janeiro and Niterói municipalities (Rio de Janeiro, Brazil) to face SARS-CoV-2

Marcelle Rodrigues¹, Antonio Oscar-Júnior¹, Pedro Castro², Francisco Mendonça³, Mariana Silva¹, Júlia Silva⁴, Thiago Fogaça⁵

¹Programa de Pós-Graduação em Geografia da Rio de Janeiro State University (PPGEO/UERJ), Rio de Janeiro, Brazil, ²Rio de Janeiro State University, Rio de Janeiro, Brazil, ³Programa de Pós-graduação em Geografia Universidade Federal do Paraná, Brazil, ⁴PPGEO/UERJ, Rio de Janeiro State University, Rio de Janeiro, Brazil, ⁵PPGEO/UFPR, Federal University of Parana, Brazil

This paper aimed to apply geographical intelligence to analyze the spread of coronavirus, between March 2020 and November 2022, in two municipalities in Rio de Janeiro state: Rio de Janeiro and Niterói, with national strategic and economic importance. Geographers have been produced important contributions in the analysis of geographical elements associated with the dissemination of diseases, taking into account their determinants/conditioners and the analysis of geographical space. To this end, analyzing the spread of diseases goes beyond its spatialization, identifying also its social determinants/conditioners and those territorial technical networks preferred for virus dissemination. Our hypothesis is that, in the absence of clinical control, geographical intelligence had the capacity to anticipate the dynamics of virus diffusion, qualifying the decision-making process by public agents and, later, with vaccination, to evaluate its impact and reorient decision-making, especially in face of growing antivaccine movement. In the first stage were identified patterns in time series data of confirmed cases and deaths with Pettit's technique and these results was analyzed together with the vaccination schedule, circulation of new strains and public policies measures. The results indicated that the emergence of less lethal strains, such as Delta variant, and vaccine advances were decisive to reduce the populations tendency to become infected. After, Kernel technique was applied to the epidemiological data, revealing the temporal-spatial dynamics of disease spread, which took advantage of the logistical infrastructure and technical network, inequalities in vaccination coverage and deficiencies in the public health system. Finally, contamination scenarios were built up and confirmed the trends of virus diffusion, demonstrating the importance of geographic intelligence for decision making in public health and the health-disease-care process as an object of interest of Geography.

A household survey; contamination related characteristics of COVID-19

Duygu Atılmış¹, Hanife Erik¹, Şahin Öztunç², Gülçin Dizman³, Gizem Karahan⁴, İlke Önder⁵, Alpaslan Alp⁶, Levent Akin⁷

¹Department of Public Health, Faculty of Medicine, Hacettepe University, Türkiye, ²Etimesgut District Health Directorate, Ankara, Türkiye, ³Department of Infectious Diseases and Clinical Microbiology, Faculty of Medicine, Hacettepe University, Türkiye, ⁴Faculty of Medicine Department of Infectious Diseases and Clinical Microbiology, Hacettepe University, Turkey, ⁵Department of Medical Microbiology, Faculty of Medicine, Hacettepe University, Türkiye, ⁶Department of Medical Microbiology, Faculty of Medicine, Hacettepe University, Türkiye, ⁷Department of Public Health, Faculty of Medicine, Hacettepe University, Turkey

Background: Household transmission studies are suitable setting to examine determinants of disease by controlling many environmental variables. This study is a prospective, case-based study evaluating the household transmission and possible risk factors on the demographical and behavioral characteristics of individuals diagnosed with COVID-19 and households. Methods: Between 1 August 2021 and 1 February 2022, individuals who were RT-PCR positive and their household members were invited to the study. Swab samples were taken from contacts and RT-PCR test was performed. Secondary attack rate (SAR) was calculated to assess household transmission. Descriptive analyzes and Logistic Regression analyzes were used in the study. Statistical Package for Social Sciences program was used for analysis. Statistical significance was accepted as $p < 0.05$. Ethical approval was obtained from Hacettepe University Ethics Committee. The research was supported by Sanofi.

Results: 42 index cases and 112 contacts were involved in the study. 43% of index

cases and 54% of contacts were women. The median age of index cases was 40 and contacts' was 34. SAR was 25%. SAR was also high in contacts sleeping in the same room (%40), hugging (%39), eating together (%30), sharing goods (%38). SAR was high in contacts of index cases who were under 40 (%22), women (%39) and vaccinated (%30). Contacts living with five or more people (OR:5.54), contacts who were spouse or children of the index case (OR:3.53) had high risk of infection. Conclusions: Living in crowded house was the most important risk factor for infection transmission. In order to prevent contagion, such measures as the use of masks in the house, frequent ventilation of house, not eating in the same environment during the quarantine period should be shared with the public and policies should be developed in this direction. Keywords: SARS-CoV-2, family characteristics, close contact transmission

¹Hospital Management Area, Local Health Authority Roma 1, Rome, Italy, ²Risk Management Area, Local Health Authority, Roma, Italy, ³Risk Management, Local Health Authority Roma 1, Roma, Italy, ⁴Information and Communication Technology, Local Health Authority Roma 1, Rome, Italy, ⁵Health Professionals Area, Local Health Authority Roma 1, Rome, Italy, ⁶Department of Economics, University of Foggia, Foggia, Italy, ⁷Risk Management Area, Istituto di Ricovero e Cura a Carattere Scientifico IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, ⁸Risk Management Area, Local Health Authority Roma 1, Rome, Italy

Background and Objective: During the COVID-19 pandemic, standard criteria were defined for optimization of spaces to be used as vaccination centers, in relation to the objectives of the 2030 UN Agenda on environmental sustainability. The aim of the study is to describe a scalable model based on the criteria of economic sustainability of the public administration, potentially expandable in other sectors such as cooperation and development.

Methods: To define the essential requirements of the new vaccination centres, a Rapid Response Team was set up and WHO guidelines were adopted following a specific checklist elaborated from a SWOT Analysis. The project was carefully calculated and measured in all phases of the vaccination cycle process. The new centers have also been designed to ensure social inclusion and user privacy.

Results: The centers were set up in about 20 days. The checklist and data collection has allowed to optimize the process and the efficiency of the linear conformation, guaranteeing a 15% increase in space for each phase of the vaccination cycle based on the length of stay of the workers. All steps have been fully digitized with 100% accuracy in data handling. In 13 months, the saving of paper filing, compared to CO2 emissions, was 64.34Kt.

Conclusions: Our model can be easily reproduced in other contexts, guaranteeing efficiency, taking advantage of new digital technologies and the quality of education.

Predicting inflection points in the disease curve through wastewater-based epidemiology: learnings from SARS-CoV-2 monitoring in Bengaluru, India

Shirish Harshe¹, Angela Chaudhuri², Chhavi Sodhi², Nitish Kumar³, Varsha Shridhar⁴, Shirish Harshe², Aditya Pangaria³

¹Swasti, India, ²Swasti, Bengaluru, India, ³Catalyst Management Services, Bengaluru, India, ⁴Molecular Solutions Care Health, Bangalore, India

Background: The covid-19 pandemic was a watershed event for wastewater-based epidemiology. It highlighted the inability of existing disease surveillance systems to provide sufficient forewarning on the existing scale of disease spread and underscored the need for effective Early Warning Systems (EWS). In keeping with WBE's potential, the covid action collab [1] launched the precision pandemic health surveillance [2] in May 2021 for equitably tracking sars-cov-2 spread in Bengaluru, India. Methods: Wastewater samples were collected from 28 networked and 46 non-networked sites. Inclusion of non-sewered sites enabled equitable disease surveillance at the wider-population level. The samples were tested for Sars-CoV-2 using a quantitative RT-PCR kit. For detecting early warning signals, the exponential weighted moving average filter was used on longitudinal viral load data. A 70% weight was assigned to the latest data-points and 30% weightage to older data. Furthermore, control chart limits and an internally-designed heuristic

model were used. Whole genome sequencing was used for genomic epidemiology. Results: The program used the aforementioned methodology to identify emerging warning signals by distinguishing the 'noise' from the 'signals,' arriving at more accurate predictions of future disease pathways and foretelling the timespan in which a contained outbreak would begin to spread. It also identified the inflection points in the epidemiological curve, which are the points of most significant inference for public health action. Basis these points, the epidemiological curve was disaggregated into four stages-normalcy, escalation, progression and de-escalation-with actionable insights for authorities at each stage. Conclusions: An EWSS enables early implementation of disease mitigation strategies. Going forward, the learnings can be harnessed by other cities for effective monitoring of covid-19 and other infectious diseases. The successful deployment of es as an ethical and equitable surveillance platform enables systems to capture the health concerns of vulnerable population groups and thus, it has great usability for showcasing the complete epidemiological arc of diseases which have a disproportionate impact on such communities. The construction of the primary health care organizational model index to fight COVID-19: scope, limits and perspectives in the Brazilian remote rural context

Aylene Bousquat¹, Simone Schenkman¹

¹University of Sao Paulo, Brazil

Background and Objective: The socio-spatial singularities of remote rural locations are rarely recognized in their classification; nor are they remembered in the formulation and implementation of public policies. These must prioritize the conditions of access to health, the form of organization of Primary Health Care (PHC) services and practices and the workforce attraction, molded in relation to local contexts, far beyond a simple opposition to the urban locale. In the context of fighting against the covid-19 pandemic, cohesion between political initiatives, organization of services and health surveillance are essential, based on the power and capillarity of PHC. Our aim is to contextualize the creation of the organizational model index for coping with COVID-19 and to analyze its application in the Brazilian rural remote municipalities.

Methods: Document and statistical analysis, including correlations, factorial and consistency analysis and logistic regression, from the construction of the instrument to its application. The index consists of six dimensions: Political Conduct, Social Isolation, Border Surveillance, Case Surveillance, Service Organization and Social Support.

Results: The determining variables for success in combating the pandemic were the state of alert for the high case rate, lower death rate than the state of origin and longer time to define containment strategies, with two sets of protectors: wealthier localities, with a lower % of income transfer or higher Family Health Strategy coverage and PHC services density. Health surveillance was essential in case detection, along with specialized care, and in the identification of deaths, with both rates being higher in the Midwest and Amazon regions.

Conclusions: The index successfully discriminated the different remote rural typologies, with a gradient being observed between the Midwest region and Northern Minas Gerais state; with the best results, whereas the Amazon region presented intermediate levels, followed by the new northeastern agricultural frontier and the northeastern Semi-arid region.

Health protection and risk reduction related to SARS-Cov-2 in health services in Brazil

Mariluce Souza¹, Patrícia Araújo², Ediná Costa¹, Yara Lima¹, Gisélia Souza¹, Ana Souto³, Bianca Paz¹, Eliana Costa², Laíse Soares²

¹Universidade Federal da Bahia (UFBA), Brazil, ²Universidade do Estado da Bahia (UNEB), Brazil, ³Universidade Federal da Bahia, Brazil

Background and Objective: The COVID-19 pandemic had an impact on health services. This study aims to analyze actions for health protection and risk reduction related to SARS-Cov-2 in health services. **Methods:** Exploratory, descriptive research, with qualitative analysis based on interviews with managers of health surveillance services and blood collection units in three Brazilian state capitals. The Iramuteq software was used to process the textual corpus and the Descending Hierarchical Classification was analyzed. Study developed with the support from the National Council for Scientific and Technological Development (CNPq).

Results: The study showed characteristics about the organization and conditions of work, about the protection of the health of workers and the population. The work at Health Surveillance during the pandemic reiterates old structural difficulties, staff shortages, insufficient training of teams and managers in the face of challenges in controlling health risks. There was a predominance of action centered on inspection/supervision and insufficient risk communication activity and guidance to the population. Joint actions of inspection, epidemiological surveillance and worker health surveillance were highlighted. Additionally, there were increased computerization, organization of remote work and joint efforts with other sectors. Regarding the effects of the pandemic on blood collection units/hemotherapy services, differences in infrastructure between services were identified. Measures such as the reorganization of the physical space to avoid crowds, measures to protect the health of workers, dissemination of information and various strategies to mobilize candidates and donors were observed. **Conclusions:** Both services required adjustments in the organization and adaptations in working conditions in order to minimize risks and preserve the protection of the health of workers and the population.

It's the stress of not knowing: a qualitative study of the impacts of COVID-19 pandemic among young adults in Canada

Geneviève Fortin^{1,2}, Marie-Pierre Sylvestre^{3,4}, Olivier Ferlatte^{1,5}, Jennifer O'Loughlin^{1,6}, Laura Struik⁷

¹School of Public Health, University of Montreal, Canada, ²Centre de recherche en santé publique (CRESP), Canada, ³École de Santé publique de l'Université de Montréal, Université de Montréal, Canada, ⁴Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Canada, ⁵Centre de Recherche en Santé Publique (CRESP), Canada, ⁶Centre de recherche du centre hospitalier de l'Université de Montréal (CRCHUM), Canada, ⁷Faculty of Health and Social Development and School of Nursing, University of British Columbia, Canada

The COVID-19 pandemic impacted populations differently across age groups. Young adults were particularly affected by lockdowns and physical distancing measures put in place to limit the spread of the pandemic. Studies demonstrate that young adults were at increased risk of psychological distress, financial stress, and work-related instability when compared to older age groups. We conducted 25 semi-structured interviews between July and August 2021 with young adults (32-34 years old) to gain insights about their perspectives on the impacts of the pandemic on their wellbeing. Data were analyzed using a reflective thematic analysis. Our study findings revealed three distinct but interconnected themes. First, "Losing oneself in chaos," represents the participants' feelings of losing their sense of self and hitting rock bottom. Second, "Gaining a sense of what matters" refers to a realization of some of the positive aspects of the pandemic, such as having more time for oneself and self-care. Third, "finding balance" reflects the need of participants to find meaning in their experiences of the pandemic and achieve balance between losses and gains. The impacts on mental health runs through the themes. Together, these themes describe the strength and the process of resilience among young adults in the context of unknown pandemic trajectories. Lessons can be learned from these findings to help inform responses to future pandemics: 1) Young adult mental health (and more specifically, facilitating the development of coping strategies) must be a public health priority; 2) Young adults' coping strategies are not fixed in time; providing ongoing mental health services is therefore essential, even months after acute phases of pandemics are over. Although participants demonstrated great resilience and coping skills, ongoing support could have helped limit the negative mental health impacts brought forward by public health measures.

Pentraxin (PTX-3) as a prognostic marker of clinical implication of COVID-19 in a cohort of healthcare workers from the A.O.U. 'G. Martino' of Messina

Giuseppe Panto¹, Anna Carpa², Alessio Ardizzone², Emanuela Esposito³, Raffaele Squeri¹

¹Department of Biomedical Sciences and Morphological and Functional Images, University of Messina, Italy, ²Department of Chemical, Biological, Pharmaceutical and Environmental Sciences, University of Messina, Italy, ³Genetics and Pharmacogenetics Unit, Department of Chemical, Biological, Pharmaceutical and Environmental Sciences, University of Messina, Italy

Introduction: Pentraxin (PTX-3) is an acute phase protein, which has significant functions in humoral innate immunity, such as regulation of inflammatory

responses, control of complement pathways, tissue repair.

Purpose: A systematic literature review was performed to better define the prognostic role of PTX3 in COVID-19 disease. This study also aims to analyse PTX-3 levels in our cohort of healthcare workers, belonging to the A.O.U. "G.Martino", who have or have not contracted the infection in their lifetime, after anti-SARS-CoV-2 vaccination (Pfizer/BioNTech Comirnaty).

Materials and Methods: The PubMed database (MEDLINE) was searched using the keywords PTX-3 and COVID-19, considering observational studies, case-control studies, cross-sectional studies, cohorts. Data extraction for this systematic update was performed by two independent reviewers. The cohort analysed consisted of workers vaccinated and supervised by the Hospital Hygiene Unit. A personal and family medical history was taken and an objective examination of the individual participants was carried out, who underwent blood sampling. Serum aliquots obtained after centrifugation were stored at -20°C. Subjects enrolled in the study were divided into 2 groups: SARS-CoV-2 positive (n=40); SARS-CoV-2 negative (n=40). Using commercially available kits, serum PTX-3 concentrations were determined using an enzyme-linked immunosorbent assay (ELISA).

Results: We included 11 studies in the systematic review. PTX-3 was evaluated in COVID-19 patients versus non-infected subjects and in COVID-19 patients in ICU versus COVID-19 patients not in ICU. For the healthcare workers in the study, demographic, clinical, laboratory characteristics were collected and reported in a dedicated database and associated with PTX-3 levels. Preliminary data showed variability in PTX-3 levels in healthy subjects correlated with sex, age, BMI, comorbidities and genetic characteristics.

Discussion and Conclusions: The results to date support the hypothesis that PTX3 levels can be considered a useful biomarker of the inflammatory response and could have a relevant clinical impact on COVID-19 disease outcomes.

Mortality from COVID-19 in Belgrade

Svetlana Miltenovic¹

¹Institute of Public Health of Belgrade, Belgrade, Serbia

Background and Objective: Coronavirus disease (COVID19) has spread worldwide in a short time. It caused a lot of deaths of infected patients. Mortality data provides insight of fatal consequences among population. Risk factors for mortality have not been well summarized, but it was possible to show findings on the association between age, gender and comorbidities from COVID-19 infection. Mortality statistics are fundamental to public health decision making. Mortality varies by time and place and its measurement is affected by some biases that have been exacerbated during the pandemic. This paper aims to present mortality from the COVID-19 pandemic in Belgrade, Serbia.

Methods: An analysis of death certificates shows an insight into the causes of death of Belgrade inhabitants. The paper presents data from database of deceased persons in Belgrade, 2012- 2021, analyzed using frequencies and incidence rates by gender, age groups, month of death.

Results: Mortality (mt) incidence rate in Belgrade 2012 - 2021 is increasing. The highest mortality rate was in 2021, 17,72/1000 population at the age 20 to 64, the highest rate was also in 2021, male (m) 6,73/1000, female (f) 3,48/1000 older age (65 and more) shows highest mt rates in 2021, male 86,92/1000, female 63,46/1000 between march 2020 and December 2021, highest mortality rate from covid19 in man and women at the age 20-64 was in October 2021 (m: 39,12/100000, f: 20,32/100.000). Man 65 and older most frequently died in December 2020 (479,67/100.000), women in October 2021 (282,04/100.000). most common comorbidity were diseases of circulatory system, endocrine, metabolic diseases, neoplasms, etc.

Conclusions: Older age (65 years old), male gender and particular comorbidities were associated with greater risk of death from COVID-19 infection in Belgrade, Serbia. These findings could help clinicians and public health authorities to prevent unnecessary death outcomes.

Have public health responses to COVID-19 considered social inequalities in health? Insights from Brazil, Canada, France & Mali

Marie-Catherine Gagnon-Dufresne¹, Lara Gautier¹, Camille Beaujoin¹, Zoé Richard², Pauline Boivin³, Stéphanie Medeiros⁴, Valéry Ridde², Kate Zinszer⁵

¹School of Public Health (ESPUM), University of Montréal, Montréal, Canada, ²Centre Population et Développement (CEPED), University of Paris, Paris, France, ³Association Miseli, Bamako, Mali, ⁴Universidade Federal de Pernambuco, Recife, Brazil, ⁵School of Public Health (ESPUM), University of Montréal, Québec, Canada

Background: Research has indicated an increased risk of self-harm repetition and suicide among individuals with frequent self-harm episodes. Co-occurring physical and mental illness further increases the risk of self-harm and suicide. However, the association between this co-occurrence and frequent self-harm episodes is not well understood. We examined the profile of individuals with frequent self-harm episodes and the association between physical and mental illness comorbidity, self-harm repetition and highly lethal self-harm acts.

Methods: The study included consecutive patients with five or more self-harm presentations to Emergency Departments across three general hospitals in the Republic of Ireland. The study included file reviews (n=183) and semi-structured interviews (n=36). Multivariate logistic regression models were used to test the association between the sociodemographic and the comorbidity variables on highly lethal self-harm acts. Thematic analysis was applied to identify themes related to the comorbidity and frequent self-harm repetition.

Findings: Most of the participants were female (59.6%), single (56.1%) and unemployed (57.4%). The predominant current self-harm method was drug overdose (60%). Almost 90 % of the participants had history of a mental or behavioural disorder, and 56.8% had recent physical illness. The most common psychiatric diagnoses were alcohol use disorders (51.1%), borderline personality disorder (44.0%), and major depressive disorder (37.8%). Male gender (OR=2.89) and alcohol abuse (OR=2.64) were associated with highly lethal self-harm acts. Major qualitative themes were a) the functional meaning of self-harm b) self-harm comorbidity c) family psychiatric history and d) contacts with mental health services. Participants described experiencing an uncontrollable self-harm urge, and self-harm was referred to as a way to get relief from emotional pain or self-punishment to cope with anger and stressors.

Conclusions: Physical and mental illness comorbidity was high among the participants. The mental and physical illness comorbidity of these patients should be addressed via a biopsychosocial assessment and subsequent interventions.

Strategies to fight the COVID-19 pandemic in remote rural municipalities of Piauí state, Brazil

Aylene Bousquat¹, Carinne Magnago¹, Angela Carneiro², Kamila Santos³

¹University of Sao Paulo (USP), Brazil, ²Federal University of Vale do São Francisco (UNIVASF), Brazil, ³Federal University of Vale do Sao Francisco (UNIVASF), Brazil

Background and Objective: Ensuring the provision of health services in rural remote municipalities (MRR) remains a challenge for the Brazilian Public Health System-SUS. This problem increased dramatically during the COVID-19 pandemic, as MMR context amplifies the devastating potential of the virus, such as insufficient supply of professionals/services and the great distance from urban centers (technological density). Our aim is to analyze the initiatives to combat the pandemic adopted in Piauí's MMR; discuss the role of primary healthcare (PHC) in the pandemic; and identify itineraries of patients diagnosed with COVID-19.

Methods: Exploratory qualitative case study, developed in two MMR of Piauí, both with less than 4000 inhabitants. Data were collected in 2022, through individual in-depth interviews with PHC professionals, SUS users SARS-Cov-2 infected and community leaders. The interviews were conducted with open questions about coping with the pandemic (professionals and leaders) and the experience and care received during the illness caused by COVID-19 (users). The interviews were recorded, transcribed and treated qualitatively, applying content analysis technique.

Results: Initiatives adopted: sanitary barriers, mandatory use of masks, social isolation, ban on parties/gatherings, closure of non-essential establishments, "covid kit", distribution, testing of suspected cases and vaccination. PHC: concentrated care for COVID-19 cases, protagonism and work overload of community workers (CHW), on barriers, home visits, vaccination and service through messaging applications. Itineraries: non or mildly-symptomatic were advised to isolate themselves at home, severe cases were referred by ambulance to reference hospitals in other municipalities in Piauí.

Conclusions: Primary care coordinated and/or actively participated in coping with the pandemic. Positive points: population bonds and CHW's assistance. Users felt supported. Distance from larger cities was not considered a protective factor against COVID-19. Previous results suggest the existence of long-term COVID-19 cases, with different clinical presentations, and an increase in mental disorders' prevalence (depression, alcoholism and drug use).

Working in the territory or in the health care facility? Community

Health Workers' (CHW) work process during the COVID-19 pandemic in Brazil

Ligia Giovanella¹, Patricia Chueiri^{2,3}, Juliana Lima⁴, Simone Schenkman⁵, Ana Chancharulo⁶, Aylene Bousquat⁵, Liliane Nakata⁵, Aline Fiori⁵

¹Oswaldo Cruz Foundation (Fiocruz), Brazil, ²Israeli Faculty of Health Sciences, Albert Einstein, Brazil, ³University of Sao Paulo, Brazil, ⁴Federal University of Oeste do Pará (UFOPA), Brazil, ⁵University of Sao Paulo (USP), Brazil, ⁶SES/ Bahia, Brazil

Introduction AND Objective: Actions during the pandemic in Brazil were characterized by a lack of federal coordination and diversified actions of Primary Health Care (PHC) teams. The family health strategy (FHS) is the hegemonic model of PHC in the country, whereas the community health worker (CHW) enhances actions to face the pandemic. The aim is to describe the CHW work process during the pandemic and its association with health indicators, municipality characteristics and the assistance provided.

Methods: cross-sectional study with probabilistic sampling of Brazilian PHC facilities (PHCF). The reference population was formed by the PHCF registered by Dec-2020, stratified considering the five country regions, totaling 945 PHCF. Data collection was carried out between Jul-Nov-2021. The inclusion criteria were operating during the pandemic and having higher-level professionals for more than six months. The manager was invited to respond to an online survey. The CHWs work was analyzed through five dimensions: inputs, work process, connectivity, surveillance and social support.

Results: 907 PHCF participated. The Southeast/South regions stand out with less CHW. Regarding the work process, CHW mostly worked in the territory or at the PHCF. In the North/Northeast regions, the work was mainly territorial, different from the other regions (p

COVID-19 and financial transfers- an analysis of Minas Gerais, Brazil, from 2020 to March 2021

Taíssa Maia^{1,2}, Allan Barbosa³, Philipe Mendes⁴

¹Secretaria de Estado de Saúde de Minas Gerais (SES-MG), Belo Horizonte, Brazil, ²Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil, ³UFMG, Brazil, ⁴CEDEPLAR/UFMG, Brazil

The study analysed the financial transfers made to directly cope with the COVID-19 pandemic in the State of Minas Gerais, Brazil, in the years 2020 and 2021, aiming at the allocation of resources by area of greater contamination, hospitalization and deaths caused. The allocation of financial resources in an emergency can boost care actions and reflect the strategic preference used to cope with the pandemic, be it preventive, health testing and promotion, hospitalizations, acquisition of supplies and expansion of beds. This paper presents in a first moment normative aspects related to transfers and sources destined to health, with special emphasis on the period that comprises the pandemic. Subsequently, to contextualize the institutional and legal ambience of Minas Gerais, Brazil, in confronting COVID-19, a research was made of the creation of well committees and working groups and normative acts with emergency actions for the territory of Minas Gerais, Brazil. Finally, results of the transfers in this period are presented as well as the analyses that indicate aspects that may hinder the effective coping of the pandemic. The results suggest, in addition to a review of the values considered inadequate to cope with, the need for an allocating review by territory proven the need for care, as well as a strategic structuring of coping with the pandemic. Minas Gerais has major public policy challenges, especially maintaining equity given territorial extension, and regional disparities, further aggravated by a pandemic state in a still developing country. It also has the greatest challenge of effectively thinking about levels of care that can minimize or mitigate the effects of the health emergency. Added to this is the need to adjust the timing of the transfer to the dynamics imposed by health needs, which would certainly allow alignment between spending and coping in "real time".

⁵Research Group of Health and Social Protection Policies, Rene Rachou Institute, Brazil, ⁶Research Group of Health and Social Protection Policies, Oswaldo Cruz Foundation / Rene Rachou Institute, Brazil

Introduction: The COVID-19 pandemic aggravated the homeless populations (HP) vulnerability. The study of targeted policies is necessary to improve response and ensure "no one is left behind" following the sustainable development goals (SDG). Brazil has a National Public Health System (SUS) and a National Social Protection System (SUAS), and both were active during the pandemic. Belo Horizonte (BH) is Brazil's third-largest city, and it is known to have a robust SUS and SUAS. The town was an example of the emergency and preparedness response, reducing potential death. However, the reach of the initiatives to vulnerable populations wasn't assessed. **Objective:** This study investigated the effectiveness of health and social protection initiatives during the pandemic tailored for HP in BH. **Methods:** A mixed method study was conducted, including the statistical analysis of HP, who received care during the pandemic, and a content analysis of the discourses collected. Primary data was collected through in-depth interviews and focus groups with policymakers, workers, and HP. The secondary data analyzed used a linkage of the city's electronic health records and the database for social protection beneficiaries (cadunico). Results indicated the implemented policies reached the HP; however, important access barriers were observed for SUAS existing services. Despite the initial decrease in consults, SUS continued to care for the HP, followed by an increase in HP with respiratory symptoms attended by primary care units. The social isolation housing for symptomatic HP was a successful new initiative jointly coordinated. Strong Non-Governmental Organization (NGO) participation was identified as the primary support during the city lockdown. **Conclusions:** The emergency and preparedness initiatives implemented during the pandemic reached the HP, with an NGO's support, attending to SDG principles. Collaborative governance and infrastructure were key to reaching HP.

Lessons from slums during COVID-19 in Indore and Agra, India towards better preparedness for future pandemics

Siddharth Agarwal¹, Kanupriya Kothiwala², Shabnam Verma², Mayaram Sharma²

¹Urban Health Resource Centre, New Delhi, India, ²Urban Health Resource Centre, India

Background and Objective: COVID-19 led to adverse effects on the urban poor relating to healthcare, nutrition, children's education, livelihood. The research aimed at learning challenges, coping method of families who faced difficulty in access to healthcare, food supplies, livelihood disruption, children's education. Lessons point to preparedness measures for future disasters.

Methods: We conducted in-person qualitative interviews, with open-ended probes with women of 40 slum families and with 10 key informants.

Results: Many Government and private hospitals refused non-COVID services during lockdown. With frontline workers on COVID duty, pregnant women, children missed essential immunisation and maternity services leading to maternal and neonatal illness, deaths. Uncertain livelihoods, low access to social benefits made slum dwellers, mostly informal workers vulnerable. Many faced food-insecurity. They resorted to private hospitals and incurred debt. Those with previously stored grains could tide through food insecurity. School closure affected children's education. Online classes were partially feasible for many. They could not afford phones, laptops and sustained internet access that better-off city dwellers had.

Conclusions: Lessons for future include having more hospitals and clinics for routine health services. Co-opting nurses, other paramedical personnel on medium-term contracts can prevent/mitigate interruption of outreach health services and help Indian, LMIC cities better deal with future disasters. Inclusion of the urban poor (who provide low-wage services to cities) in extending essential services, and social protection schemes is vital during future pandemics. Ensuring access to food supplies mitigates suffering of the urban poor. Decentralised free food distribution with the help of schoolteachers, other government functionaries is crucial to prepare for similar future crises. An employment guarantee program for the urban poor similar to India's Rural Employment Guarantee Scheme needs to be rolled out. Onsite classes in settlements with open spaces nearby is a way to extend education to deprived children during future disasters/pandemics.

Symptom presentation and quality of life are comparable in Myalgic Encephalomyelitis/Chronic Fatigue Syndrome and post COVID-19 condition

Breanna Weigel¹, Natalie Eaton-Fitch¹, Kiran Thapaliya¹, Sonya Marshall-

Gradisnik¹¹National Centre for Neuroimmunology and Emerging Diseases, Menzies Health Institute Queensland, Griffith University, Australia

Background and Objective: Considerable overlap exists in the clinical presentation of Post COVID-19 Condition and Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS). The current study aimed to compare symptoms and patient-reported Quality of Life (QoL) among people with Post COVID-19 Condition and ME/CFS in Australia. **Methods:** QoL data was collected from n=61 ME/CFS patients, n=31 Post COVID-19 Condition patients, and n=54 Healthy Controls (HCs) via validated instruments. The ME/CFS and Post COVID-19 Condition participants also provided self-reported severity and frequency of symptoms derived from the Canadian and International Consensus Criteria for ME/CFS and the World Health Organization case definition for Post COVID-19 Condition. Study variables were compared with Chi-square, Fisher's exact, Fisher-Freeman-Halton, Mann-Whitney U, and Kruskal-Wallis H tests using Statistical Package for the Social Sciences version 29. Symptom clusters among the two illness cohorts were identified with hierarchical cluster analysis.

Results: ME/CFS was associated with a higher prevalence of short-term memory loss (p=0.039), muscle weakness (p<0.001), lymphadenopathy (p=0.013), and nausea (p=0.003). People with ME/CFS also reported more severe light-headedness (p=0.011) and more frequent unrefreshed sleep (p=0.011), but less frequent heart palpitations (p=0.040). Symptom prevalence, severity, and frequency were otherwise comparable. Few differences existed in the QoL of the two illness cohorts, both of which returned significantly impaired QoL scores when compared with HCs (p<0.001). Cluster analysis of symptom prevalence revealed four clusters: 1) Low gastrointestinal, low neurosensory; 2) Moderate gastrointestinal, low orthostatic and memory loss; 3) Moderate gastrointestinal, high orthostatic and memory loss; and 4) High gastrointestinal, high pain, which did not differ in sociodemographic information, illness status, or diagnostic criteria met. **Conclusions:** Post COVID-19 Condition and ME/CFS are remarkably similar in presentation and, like ME/CFS, Post COVID-19 Condition has a profound and negative impact on patient QoL. Gastrointestinal symptoms may have a role in determining ME/CFS and Post COVID-19 Condition subtypes.

DOI: 10.18332/popmed/165669

How to reshape trade for vaccine equity: gaps in policy discourse

Toby Pepperrell¹, Alison McCallum², Toby Pepperrell¹, Alison McCallum¹¹University of Edinburgh, United Kingdom, ²Centre for Population Health Sciences, United Kingdom

Background and Objective: While trade-related impacts on health are often difficult to assess, the COVID-19 pandemic revealed vaccine inequity as a unifying health need, an example of trade as a commercial determinant of health (CDH). We analysed stakeholder views and priorities regarding trade and vaccine equity, exploring where policy and action may shift to reshape trade relationships for wider transition to wellbeing economics, and to build a transferable analytical framework for policy analysis of trade as a CDH.

Methods: We undertook a systematic literature search (01/03/22-01/06/22) exploring major stakeholder libraries, Policy Commons, and linked reference searches from 2010. Stakeholder views on contributors to vaccine inequity were mapped onto an adapted rights, responsibilities, redistribution framework as causal process observations to create a network of policy recommendations.

Results: The available policy advice was fragmented and revealed significant gaps. While existing tools and legal flexibilities were acknowledged, the deep-set politico-economic barriers that limit successful use were not. Technocratic solutions lacked incentives or requirements for cooperation. The determinants of vaccine equity and application of collaborative mechanisms, other than trade agreements, were rarely considered. The shrinkage of policy space inhabited by governments, public health, and NGOs by current approaches to free trade agreements was not addressed. Few spaces for real change were explored, even when distributional inequity was clear.

Conclusions: Our analytical framework illustrates gaps in the consideration of policy options and implementation mechanisms that would help address current levels of vaccine inequity. The narrow policy discourse and resistance to implement existing mechanisms designed to mitigate inequity has delayed essential action and limited co-creation of solutions. In addition to a TRIPS+ waiver, trade-related factors that increase health inequity must be tackled explicitly. Alternative collaborative mechanisms with the potential for real change must be prioritised above trade agreements that serve corporate over community interests.

Assessment of excess mortality in Italy in 2020-2021 as a function of selected macro-factors

Emiliano Ceccarelli¹, Giada Minelli¹, Giovanna Lasinio²¹Istituto Superiore di Sanità, Italy, ²Sapienza University of Rome, Italy

Background: Excess mortality (EM) can reliably capture the impact of a pandemic, as the increase in deaths is not related to the COVID-19 deaths alone. This study aims at assessing the numerous factors associated with EM during the pandemic in Italy.

Methods: Mortality records (ISTAT 2015-2021) aggregated in the 610 Italian Labour Market Areas (LMAs) were used to obtain the EM P-score to correlate EM with socioeconomic variables. A two-step analysis was implemented: 1) Functional representation of EM and clustering using the Discriminative Functional Mixture Model. 2) Distinct functional regression by cluster to assess relationships between EM and covariates.

Results: The LMAs are divided into 4 clusters: 1 low EM; 2 moderate EM; 3 high EM; 4 high EM-first wave. From the functional regression models estimate, Low-Income showed a negative association with EM clusters 1 and 4. Population density and percentage of over 70 did not seem to affect EM significantly. Bed availability positively correlates with EM during the first wave. The employment rate positively correlates with EM during the first two waves, becoming negatively associated when the vaccination campaign began.

Conclusions: The clustering shows diverse behaviors by geography and time, the impact of socioeconomic characteristics, and local governments and health services responses. The LMAs allow drawing a clear picture of local characteristics associated with the spread of the virus. The employment rate and the beds availability trends confirmed that essential and health workers were at risk, especially during the first wave. The beds availability trend shows also the nosocomial nature of the disease during the pandemics first wave. The proportion of the elderly is mostly not significant, except for two clusters with lower EM during the first wave, showing a positive association with EM.

DOI: 10.18332/popmed/165689

COVID-19 conspiracy beliefs, government legitimacy and societal priorities in the age of pandemic

Aldo Rosano¹, Pasquale Padova¹, Luca Regazzi², Chiara Cadeddu²¹National Institute for Public Policy Analysis, Rome, Italy, ²Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy

Background: Conspiracy beliefs can be a major hindrance causing a lack of compliance with public health measures and, more in general, a government's ability to enforce rules adopted to protect the public. During the pandemic, trust in scientists, government, and its responses to the health emergencies represented crucial questions. The study examines conspiracy beliefs, government legitimacy, and societal priorities in relationship with COVID-19 in 17 European countries: Bulgaria, Croatia, Czechia, Estonia, Finland, Greece, Hungary, Iceland, Italy, Lithuania, Netherlands, North Macedonia, Norway, Portugal, Slovakia, Slovenia, Switzerland using data from the 10th round of the European Social Survey held in 2021-2022.

Results: Respondents are 33.351 aged 15 or more. Trust in scientists ranges from 54% in Slovakia and Bulgaria to over 84% in Finland and Iceland. One-fourth of respondents believe that groups of scientists manipulate evidence to deceive the public, from a high of 50% in Bulgaria and North Macedonia to a low of 20% in Italy, Switzerland, and Nordic countries. About 56% of respondents affirm that it is more important to prioritise public health when fighting a pandemic rather than economic activity, with slight differences among countries. Most respondents are satisfied with the way health services coped with the coronavirus pandemic, less in Bulgaria and Slovakia (80%). Those more prone to conspiracy, who believe in manipulation by scientists, have a lower education, older age, and lower interest in political and cultural life.

Conclusions: This study paints a picture of the opinions of European citizens on government legitimacy and priorities related to the pandemic. The share of European people prone to conspiracy thinking is large, especially in Eastern Europe. This is of great concern for compliance with rules to be adopted during health emergencies.

Popul. Med. 2023;5(Supplement):A375

DOI: 10.18332/popmed/165690

Trust in the scientific community and conspiracy thinking in Italy during the COVID-19 pandemic

Chiara Cadeddu¹, Luca Regazzi¹, Aldo Rosano²¹Department of Life Sciences and Public Health, Università Cattolica del

Sacro Cuore, Rome, Italy, ²Unit of Statistics, National Institute for Public Policies Analysis (INAPP), Rome, Italy

Background and Objective: Trust in scientists (TiS) plays a major role in determining people's acceptance of evidence-based health-related measures. Previous research shows that in Italy lack of TiS is associated with a higher inclination towards conspiracy beliefs (ItCB). Our aim is to analyse TiS and ItCB among Italians during the COVID-19 pandemic.

Methods: The European Social Survey (ESS) is a biennial survey measuring attitudes, beliefs, and behaviours across Europe. We present a descriptive analysis of data from its 10th round, conducted in 2022, concerning Italians' TiS and ItCB, along with their relationship with socio-cultural-demographic variables. **Results:** The sample is composed of 2,640 respondents, with a median age of 53 years, of which 51.7% are females. Most respondents declare having high levels of trust in scientists (69.3%). However, only 49.8% of them disagree that groups of scientists manipulate evidence to deceive the public. While 58.9% of those with high levels of trust expectedly disagree with evidence manipulation by scientists, 15.7% of them are concerned with it. Of those trusting science, 51.5% think people can usually be trusted (against 29.6% of those distrustful of science). Conversely, among those questioning scientists' integrity, a lower proportion trust people in general (33.0%) compared to their counterparts (50.6%). Both higher trust in scientists and stronger belief in scientists' integrity are associated with higher education (high school/university), younger age, and being female. A similar association emerges with higher interest in politics, with left-wing political placement, with better rating of health services and with living in a big city or suburbs.

Conclusions: Although most Italians show high TiS and low ItCB, there is a relevant cluster of citizens with an opposite profile. The common determinants of lower TiS and higher ItCB must be better understood and addressed to ensure a higher effectiveness of public health measures during emergencies.

The impact of COVID-19 pandemic on depression and anxiety symptoms: findings from the United Arab Emirates healthy future cohort study

Maryam Marri¹, Manal Blooshi¹, Tamadher Ameri¹, Amar Ahmad¹, Andrea Leinberger-Jabari¹, Abdishakur Abdulle¹, Manal Taimah¹, Thekra Zaabi¹, Khaloud Remeithi¹, Ayesha Hosani¹, Scott Sherman², Raghib Ali¹

¹New York University Abu Dhabi, United Arab Emirates, ²New York University, United States

Background and Objectives: Concerns about mental health were raised during the COVID-19 pandemic. We investigated the prevalence of depression and anxiety symptoms among the participants of the United Arab Emirates Healthy Future Study (UAEHFS); a cohort study. We further explored the change in the prevalence of depression symptoms among those with comparable pre-pandemic data.

Methods: A sample of UAEHFS participants was invited to complete a COVID-19 online questionnaire during the pandemic. Depression and anxiety symptoms were assessed using the Patient Health Questionnaire Depression Scale (PHQ-8) and the Generalized Anxiety Disorder-7 Scale (GAD-7) respectively. Unpaired analyses were done to examine the effect of COVID-19 on depression and anxiety symptoms during the pandemic. Paired analysis was conducted to examine the change in depression symptoms.

Results: During the pandemic, we reported a prevalence of 32.8% (95% CI: 27.0, 39.1) for depression and 26.4% (95% CI: 21.0, 32.6) for anxiety symptoms. Younger people reported higher levels of depression (40.4%) and anxiety (34.5%) symptoms. Females reported higher levels of depression (36.5%) and anxiety (32.7%) symptoms. In paired analysis, the prevalence of depression symptoms during the pandemic was 34% (95% CI: 26.5, 42.4) compared to 29.9% (95% CI: 22.7, 38.1) before the pandemic. No statistically significant difference was observed, p-value = 0.440. Adjusted multivariate logistic regression models for PHQ-8 and GAD-7 during the pandemic showed that participants, who were experiencing flu-like symptoms, had higher odds of reporting depression symptoms compared to those without symptoms. Age was significantly negatively associated with anxiety symptoms.

Conclusions: We found that depression and anxiety symptoms were more prevalent among young people and females. However, we did not find a significant change in the prevalence of depression symptoms among those with comparable pre-pandemic data. Identifying vulnerable groups and understanding trajectories through longitudinal studies would help with planning for effective mental health interventions.

³School of Dental Medicine, University of Puerto Rico, Puerto Rico

Introduction: Puerto Rico's network of Federally Qualified Health Centers (FQHCs), which consists of 22 centers with 86 satellite clinics, is the backbone of the island's primary health care system. Therefore, it is extremely important to study the effect of the COVID-19 pandemic on the delivery of services and the adaptation strategies implemented to continue operations. The research Objectives were to identify, measure and describe the effect of the pandemic on the FQHCs' continuity of operations, financial stability, and strategies implemented. Finally, we sought to develop recommendations to strengthen the FQHCs' continuity of operations for future emergencies.

Methods: A mixed research Methodology was utilized in which quantitative and qualitative approaches were combined. Of the 21 FQHCs that qualified for the study, 17, or 81.0%, provided the research team with data on service utilization, patients served, staff, operating costs, and revenue received from 2018 to 2020. Moreover, individual and group interviews were conducted with patients, members of the Board of Directors, community leaders, clinical staff, and senior management from a sample of seven FQHCs. We then triangulated the data and information collected from both components.

Results: Puerto Rico's FQHCs demonstrated great flexibility, adaptability, and innovative capacity during their response to the pandemic. The primary health care services provided played an important role in assisting, supporting, and mitigating the impact of COVID-19 on the health of thousands of vulnerable persons, families, and communities around the island.

Conclusions: While there is clearly much work to be done to overcome this public health challenge, the current moment offers an opportunity for Puerto Rico's local and state political leaders to use the creativity, innovations, and lessons learned from the FQHCs' response to the COVID-19 pandemic to maintain and strengthen an equitable primary health care system that is resilient and accessible in the future.

Investigating household transmission of SARS-CoV-2: an analysis of 1453 households

Ecem Şensoy¹, Ahmet Emecen¹, Salih Keskin¹, Ahmet Süner¹, Neslişah Şiyev¹, Öykü Turunç², Belgün Ünal³

¹Department of Public Health, Faculty of Medicine, Dokuz Eylül University,

Türkiye, ²Mardin Provincial Health Directorate, Turkey, ³Department of Public

Health, Dokuz Eylül University Faculty of Medicine, Turkey

Background&Objective: Household transmission is the dominant way of SARS-CoV-2 transmission. Implementing strict protective measures is difficult to apply within households. In this study, we aimed to investigate individual and household-level factors contributing to SARS-CoV-2 transmission among household members. **Methods:** A total of 1453 households belonging SARS-CoV-2 RT-PCR-positive people who applied to Dokuz Eylül University Hospital in Izmir, Turkey between November 1st and 30th, 2020 were included in the study. Individual and household-level data were collected via telephone calls. Multilevel logistic regression models were conducted with individual and household-level variables to predict SARS-CoV-2 transmission. The transmission was considered as being SARS-CoV-2 RT-PCR positive or having symptomatic illness for the people who were epidemiologically linked to the confirmed case.

Results: Among the 5228 people coming from 1453 households, 3194 people were symptomatic (61.1%). The null model revealed there is a significant variation among households (Variance partition coefficient-VPC: 21%). According to the full model which included individual and household-level variables and had adjustment for household size and population (VPC: 20%); significant individual variables were being over age 65 (odds ratio-OR, 95% confidence interval-CI: 7.85, 5.38-11.45), having a chronic disease (OR, 95%CI: 1.60, 1.31-1.96) and being a nuclear family member (OR, 95%CI: 3.30, 2.71-4.1). For household-level variables, having a housekeeper in the household (OR, 95%CI: 2.44, 1.00-5.96), never wearing a mask (OR, 95%CI: 1.60, 1.15-2.23), eating at the same table (OR, 95%CI: 1.92, 1.42-2.60) and traveling in the same car (OR, 95%CI: 1.58, 1.17-2.13) were significant. Gender, natural ventilation, type of building and being isolated in a separate room were not statistically significant.

Conclusions: The results of the study may represent a useful contribution to understanding the household transmission of SARS-CoV-2. In line with the study

results, mitigation strategies in the future could be planned for the household transmission of SARS-CoV-2-like respiratory viruses.

Impact of COVID-19 in Irish Nursing Homes: an assessment of variables associated with performance during first wave of the pandemic

John Loughrey¹, Codd Mary^{2,1}, Conyard Karl^{2,1}, Parnian Jalili¹, Eamonn Gormley¹, Patrick Wall³

¹University College Dublin, Dublin, Ireland, ²ASPHER, Ireland, ³University College Dublin, Ireland

Background and Objective: The COVID-19 pandemic has had a devastating impact globally, particularly on long-term care facilities (LTCF), in which elderly and vulnerable populations reside. In Ireland, LTCF residents were severely affected in the first wave; 3-5% of all LTCF residents died in this timeframe, accounting for 56% of all COVID-19 deaths in the country. Continued investigation of the reasons for this is vital. The aim of this research was to establish whether risk factors for high LTCF mortality established elsewhere were significantly associated with Irish LTCF performance in the first wave. Specifically, cumulative county incidence rate, facility size, occupancy rates, private vs public ownership and compliance with health inspection regulations were investigated.

Methods: The main outcome considered was deaths per 100 beds. Data on crude mortality were available for 580 LTCFs up to 28 May 2020. Estimates of occupancy and compliance with regulations were averaged for these LTCFs from a novel dataset of 1130 available LTCF regulatory inspection reports up to January 2022. Focused geographic, temporal and correlation analyses looked at the relationship between deaths and studied variables. Bivariate and multivariate regression analysis was carried out to predict LTCF performance.

Results: The most significant predictor of deaths from COVID-19 in LTCFs resulting from this research was cumulative COVID-19 incidence in a county followed by facility size, in concordance with international literature. Occupancy rates and ownership factors were not found to have a significant effect. Compliance with regulatory standards showed borderline significant association with worse performance.

Conclusions: In conclusion, to protect LTCF residents in Ireland in the present and for potential future pandemics, attention should be paid to monitoring and suppressing local incidence rates, a move towards smaller facilities with individual rooms and closer attention to compliance with regulatory guidelines.

Flexibilization of regulations of health professionals' practices in response to the COVID-19

Ana Stralen¹, Cristiana Carvalho¹, Sábado Girardi¹, Alice Massote¹, Mariangela Cherchiglia¹

¹Federal University of Minas Gerais, Brazil

Background and Objective: Brazil is one of the countries most affected by the COVID-19 pandemic. Given its rapid spread, governments and health services had to act with the same speed to expand their health workforce capacity. This study aimed to identify strategies related to optimizing the health workforce, especially those related to the flexibilization of the scope of practice regulation of health professionals worldwide and in Brazil.

Methods: We conducted a scoping review in September and October of 2020 following the stages proposed by the Joanna Briggs Institute to identify worldwide regulatory strategies related to the flexibility of the scope of practice regulation of health professionals. After classifying the strategies, we investigated how and which strategies were implemented in Brazil.

Results: A total of 36 documents were identified and grouped into the type of strategies, professionals involved, and country of references. We identified six categories of strategies (1) enhancing scope of practice; (2) task shifting between health professionals; (3) telemedicine; (4) licensing and recruitment of idle workers; (5) recruitment of workers from other regions/states; and (6) education and training. Among the most important strategies identified, in several countries, including Brazil, in response to health workforce shortages and overloaded professionals, was the willingness to adapt, expand, and redistribute workers' functions to deal with the rapid changes. However, in Brazil, we encountered several limitations due to rigid workforce regulations.

Conclusions: Many countries and health organizations have experimented with new ways to unlock the potential of the health workforce. This review points to the urgent need for reforms in workforce regulation in Brazil to optimize and permit the use of full skillsets of the health workforce so that they can meet the population's

constant needs and adapt to new demands.

Healthcare assistant and carers in Ireland: battling for resources during SARS CoV-2, Wave 1: a rapid-response survey

Karl Conyard^{1,2}, Allison Metcalfe³, Nicole McAllister⁴, Parnian Jalili⁵, John Loughrey⁵, Patrick Wall⁶, Mary Codd⁷

¹Association of Schools of Public Health in the European Region (ASPHER), Dublin, Ireland, ²University College Dublin, Dublin, Ireland, ³HCA and Carers Ireland, Kildare, Ireland, ⁴University College Dublin, Ireland, ⁵Woodview House, School of Public Health, Physiotherapy and Sports Science, University College Dublin, Ireland, ⁶School of Public Health, Physiotherapy and Sports Science, University College Dublin, Ireland, ⁷School of Public Health, Physiotherapy and Sports Science, University College Dublin, Association of Schools of Public Health in the European Region, Dublin, Ireland

Background and Objective: The first wave of SARS-CoV-2 enveloped the world with uncertainty and fear. At-risk-populations including the elderly, those living with disabilities and those who were immuno-compromised relied heavily on frontline healthcare staff for much of their care. In Ireland, little is known of key workers at the helm of this effort, notably Healthcare Assistants and qualified carers (HCAs). This study highlights how HCAs managed in the most difficult period of the SARS-CoV-2 pandemic and the already delicate systems in which they function.

Methods: A mixed method rapid-response survey was carried out by the HCA Research Group at University College Dublin in conjunction with HCA and Carers Ireland, a national social association for healthcare assistants and qualified carers which provided education and assistance for research activities for policy change. The rapid-response survey was made available online for a 24-hour period in April 2020. The information was gained in a confidential and anonymous manner.

Results: Of 456 responses received within 24-hours, the majority worked in the private sector (56%). Homecare was the most common healthcare environment (44%) followed by nursing homes (29%). At the time of the survey 31% had not received any training in infection prevention and control (IPC), 29% of respondents worked in different locations weekly; 38% did not have access to an adequate supply of personal professional equipment (PPE); 55% did not have appropriate PPE for their duties; 29% did not feel supported at work.

Conclusions: Fear of the unknown was a common concern early in the pandemic. SARS-CoV-2 was an emerging infection about which little was known and early information was conflicting. Lack of prior IPC training and inadequate supplies of appropriate PPE in residential care settings reflected failure to direct resources to these important preventative measures. HCAs and carers are a vital source of this important information.

SARS-CoV-2 Delta and Omicron variant transmission and the impact of vaccine in schools and child-care settings in Australia

Archana Koirala^{1,2}, Kristine Macartney³, Noni Winkler², Helen Quinn³, Evangeline Gardiner², Bette Liu⁴, Joanna Forbes⁵, Caroline Sharpe⁵, Trish Tuskenbroek⁶, Nicholas Wood³

¹University of Sydney, Australia, ²National Centre for Immunisation Research and Surveillance, Australia, ³National Centre for Immunisation Research and Surveillance, University of Sydney, Australia, ⁴National Centre for Immunisation Research and Surveillance, University of New South Wales, Australia, ⁵New South Wales Health, Australia, ⁶New South Wales Department of Education, Australia

Background: Over 214 million students globally have been affected by school closures during the COVID-19 pandemic. To address knowledge gaps on transmission of SARS-CoV-2 delta (B.1.617.2) and omicron (B.1.1.529) variants in educational settings we examined virus transmission in schools and early childhood education and care settings (ECECs) in New South Wales (NSW), Australia in relation to mitigation measures, including COVID-19 vaccination.

Methods: Secondary transmission from children and adults with laboratory-confirmed SARS-CoV-2 infection who attended a school (n=3170) or ECECs (n=5800) while infectious was investigated over two periods: 1) June 16 to September 18, 2021 (delta outbreak), and; 2) October 18 to December 18, 2021 (delta and omicron; schools only). Close contacts of cases underwent 14 days quarantine and SARS-CoV-2 nucleic acid testing. Secondary attack rates (SARs) were calculated and compared with state-wide notification data, school attendance, and vaccination status.

Findings: 1187 schools and 300 ECECs had students (n=1349) or staff

(n=440) attend while infectious. Of 24279 contacts investigated, most (93.2%; 22627/24279) were tested and 912 secondary cases identified. The secondary attack rate (SAR) was 5.6% in 139 ECECs and 3.5% in 312 schools. The risk of becoming a secondary case was higher in unvaccinated school staff (OR 5.7; 95%CI: 2.0–16.0), particularly ECEC staff (OR 11.3; 95%CI: 4.5–28.4) and unvaccinated school students than in vaccinated school staff. SARs were similar for delta (4.6%) and omicron BA.1 (5.0%) in the unvaccinated and higher compared with vaccinated contacts (1.3% and 2.2%, respectively). Increasing school attendance rates raised case incursions and secondary case numbers, but not community-wide infection rates.

Interpretation: Vaccination reduced SARS-CoV-2 transmission rates in schools, although less so for omicron than delta variants. Despite higher community-based transmission rates, in-school transmission remained low and stable with high attendance, suggesting that community restrictions, rather than school closures, best mitigated COVID-19 impacts.

Quality of National Disease Surveillance Reporting before and during COVID-19

Hanevi Djasri¹, Muhammad Hardhantyo¹, Aldilas Nursetyo¹, Bernadetta Rachela¹, Andriani Yulianti¹

¹Center for Health Policy and Management, Indonesia

Background: Global COVID-19 outbreaks in early 2020 have burdened health workers, among them surveillance workers who have the responsibility to undertake routine disease surveillance activities. The aim of this study was to describe the quality of the implementation of Indonesia's Early Warning and Response Alert System (EWARS) for disease surveillance and to measure the burden of disease surveillance reporting quality before and during the COVID-19 epidemic in Indonesia. Methods: A mixed-method approach was used. A total of 38 informants from regional health offices participated in Focus Group Discussion (FGD) and In-Depth Interview (IDI) for informants from Ministry of Health. The FGD and IDI were conducted using online video communication. Yearly completeness and timeliness of reporting of 34 provinces were collected from the application. Qualitative data were analyzed thematically, and quantitative data were analyzed descriptively.

Results: Major implementation gaps were found in poorly distributed human resources and regional infrastructure inequity. National reporting from 2017–2019 showed an increasing trend of completeness (55%, 64%, and 75%, respectively) and timeliness (55%, 64%, and 75%, respectively). However, the quality of the reporting dropped to 53% and 34% in 2020 concomitant with the SARS-CoV2 epidemic.

Conclusions: Report completeness and timeliness are likely related to regional infrastructure inequity and the COVID-19 epidemic. It is recommended to increase report capacities with an automatic EWARS application linked systems in hospitals and laboratories.

High coverage and equitable distribution: status and correlates of COVID-19 vaccine uptake in two vulnerable sites in Bangladesh

Islam Muhammed Nazmul¹, Emmanuel Bonnet², Malabika Sarker¹, Manuela De Allegri³, Valéry Ridde²

¹BRAC James P Grant School of Public Health, BRAC University 22 Sheikh Shaheb Bazar Road, Azampur, Dhaka-1205, Bangladesh, ²Institut de recherche pour le développement, ³Heidelberg Institute of Global Health, Heidelberg University Germany

Bangladesh has fully vaccinated 76 per 100 population against COVID-19. However, ensuring higher coverage in vulnerable sites is subject to various challenges. We report the COVID-19 vaccine uptake and its correlates among the adults residing in two vulnerable sites in Bangladesh.

We conducted a cross-sectional study between August and September 2022 in two sites with a high prevalence of in- and out-migration. Duaripara, a slum in northeast Dhaka, was selected as the in-migration site. Tala, a disaster-prone sub-district located in southwest Satkhira, was selected as the out-migration site. We surveyed 2502 adults (1239 from Duaripara; 1263 from Tala) from 1211 randomly selected households. We reported coverage and examined associations between the uptake and background characteristics using Poisson, and Two-part regression models. Additionally, we checked for spatial autocorrelation to assess equitable distribution geographically.

The coverage for the first and second doses of the COVID-19 vaccine were about 91% and 80.3% in Duaripara, and 96.6% and 92.2% in Tala, respectively. For the

third dose, it was about 14% in Duaripara and 52.4% in Tala. For Tala, the uptake was significantly associated with age, education, and occupation. Interestingly, it was associated positively with television access (Incidence rate ratio: 1.04, p-value = 0.01) and negatively with smart-phone access (IRR: 0.96, p-value = 0.04). Respondents who temporarily migrated were more likely to remain unvaccinated (IRR: 0.90, p-value <0.001). For Duaripara, age and occupation were associated with the uptake. For both sites, the uptake was neither associated with income or wealth, nor correlated with geographical location, indicating equitable distribution. The credit for high COVID-19 vaccine coverage in Bangladesh dates back to its long history of implementing immunization programs through community mobilization and creating demand through health education. However, full vaccination is essential to reduce COVID-19-related deaths. Health authorities need to pay special attention to vulnerable sites.

Roles of health professionals in infodemic management related with the novel coronavirus disease

Dilek Aslan¹, Selen Yegenoglu¹, Bilge Sozen Sahne¹, Meltem Sengelen¹

¹Hacettepe University, Faculty of Medicine, Department of Public Health, 06100, Sıhhiye, Ankara, Türkiye

Background and objective: Infodemic is a global threat. This study is carried out with one of the qualitative research methods, in-depth interview, aimed determining the views and roles of healthcare professionals on the widespread "infodemic" during the COVID-19 pandemic. Secondary aim is to develop possible solution proposals regarding the roles of healthcare professionals in the fight against infodemic.

Methods: Within the scope of the research, in-depth interviews were held with 23 academic staff from the field of health at Hacettepe University (Health) Campus in the 2021-2022 period. Eight physicians, 5 pharmacists, 3 nurses, 3 dieticians, 2 dentists, 1 physiotherapist and 1 child development specialist participated. Due to the pandemic conditions, various online meeting platforms were used for the interviews. The interviews were transcribed by the researchers. Themes categories and codes were determined for content analysis. In the end, categories and codes compatible with 6 themes were determined. The Project was funded by Hacettepe University Scientific Research Projects Coordination Unit (Nb. 19340). Results: In the interviews, participants stated that infodemic was a problem before COVID-19. Thus, its frequency became more visible with the pandemic. The infodemic, in general, has made life difficult in many ways. All participants think that health workers have a significant role in the fight against infodemic. Although being a health worker is the common ground in the stated roles, different occupational groups also underlined their expertise-specific roles. Besides they declared that the fight against infodemic was stated as a multidisciplinary field of study and an institutional approach must be developed. Conducting future studies with an interdisciplinary approach, development of individual and community education, professionalism and strengthening of healthcare and other systems were emphasized.

Conclusion: Planning sustainable programs will be helpful to respond to the actual needs in infodemic management.

One size does not fit all! barriers and drivers towards COVID-19 prevention measures in the Netherlands

Valerie Eijrond¹, Nora Bünemann¹, Nicky Renna¹, Anja Schreijer¹

¹Pandemic and Disaster Preparedness Center Netherlands

Background and Objective: Identifying barriers and drivers towards health protective behaviours is an important step when designing interventions because a one-size-fits-all approach may not reach the whole population. The objective of this project is developing, testing and evaluating targeted interventions for underserved groups during pandemics in the Netherlands. We did so by using the Tailoring Immunization Programmes (TIP) approach developed by the World Health Organization (WHO). We now present the findings of the situation analysis. The aim was to get an overview of existing barriers and drivers to COVID-19 vaccination, testing and adherence to measures, and the interventions initiated in the Netherlands.

Methods: We conducted a literature scan followed by semi-structured interviews with 23 experts. The data were discussed and enriched during a national expert meeting facilitated by the Pandemic and Disaster Preparedness Center (PDPC) and the WHO regional office for Europe.

Results: The findings revealed that underserved groups are heterogeneous, with different and multifactorial barriers (e.g. mistrust in the government, mis- and

disinformation, accessibility) and drivers (e.g. self-protection, moral duty to protect others). Research has predominantly focused on vaccination behaviour among the general population. Over 45 interventions and projects were identified. These interventions were designed with limited use of behavioural insights, due to limited available qualitative research and lack of time during the crisis to gain such insights.

Conclusion: More research is needed to understand the differences between underserved groups. Although many interventions were initiated, there is a need to design tailored interventions informed by insights, and the need for monitoring and evaluation. In the next phase of this project, we will explore the barriers and drivers to COVID-19 vaccination among elderly migrants using a qualitative approach. These results will be used to develop tailored interventions to improve vaccination uptake and can inform long-term pandemic preparedness and response.

DOI: 10.18332/popmed/163706

A feasibility study about covid-19 patients management in general hospital wards in Italy: an organizational assessment approach

Giulia Libero¹, Valerio Bordino¹, Paolo Ragusa¹, Alessandro Prinziavalli¹, Palma Desantis², Paola Gatti², Adriana Trombotto², Davide Minniti², Roberta Siliquini³, Fabrizio Bert⁴

¹University of Turin, Department of Public Health Sciences, Italy, ²Health Local Unit ASL TO3 Italy, ³University of Turin, Department of Public Health Sciences; AOU City of Health and Sciences of Turin, Italy, ⁴University of Turin, Department of Public Health Sciences; Health Local Unit ASL TO3, Italy

Background and objectives: In the COVID-19 pandemic, healthcare-associated transmission has been a major concern and hospitals had to implement ways of isolating COVID-19 patients. Our study aimed to identify public health variables affecting the organizational approach of managing COVID-19 positive patients in hospital wards and describe our experience in three hospitals of Northern Italy.

Methods: We searched in the scientific literature organizational models for cohorting patients with COVID-19. We created a focus group and a SWOT analysis in order to define the best organizational assessment for each hospital.

Results: There is poor literature about organizational assessment for cohorting COVID-19 patients. We analyzed the floor plans, the hospital ventilation system, the personal protective equipment (PPE) use during a shift, workload for healthcare workers (HCW) and patient safety.

The variables that we identified were: 1) structural variables: presence or absence of single rooms with dedicated bathroom in hospital wards, presence or absence of an anteroom for donning and doffing, ventilation system; 2) patient care variables: safe patient care, patient well-being, necessity to move patient for diagnostic tests; 3) HCW variables: use of PPE, HCW workload; 4) Economic variables: costs for PPE supply, additional personnel costs, loss of COVID-free beds. In particular, we focused our attention on structural variables, patient care variables, HCW variables and economic variables.

Conclusions: The analysis of variables led us to define different organizational assessments for the three hospitals. Our evaluation showed that Hospital structure is the most important variable to evaluate. If there are no single rooms and no dedicated bathroom, it is impossible to guarantee isolation of patients. The cost in PPE use and for additional personnel may be higher with the single room isolation system than with the ward isolation system. Feasibility studies are needed to define which organizational model best suits the hospital setting.

Identifying essential resources for pandemic response: an international delphi study within the EU-PANDEM-2 project

Berend Beishuizen¹, Mart Stein¹, Anne-Romy Peelen¹, Joeri Buis¹, Alma Tostmann², Caroline Green³, James Duggan³, Máire Connolly³, Chantal Bleeker-Rovers², Aura Timen¹

¹National Institute for Public Health and the Environment, Netherlands, ²Radboudumc, Netherlands, ³University of Galway, Ireland

The ongoing COVID-19 pandemic highlights the crucial role of healthcare and public health resource management, where shortages impair the immediate response to a pandemic resulting in increased transmission and delayed patient care. In the European PANDEM-2 project, we aimed to identify essential resources for pandemic planning in the context of an emerging viral respiratory illness.

We performed a Delphi study consisting of a systematic literature review, a structured questionnaire and two international consensus rounds. Resources were categorized as material, human or pharmaceutical. A panel of public health experts (PHEs) and a panel of clinicians participated in the questionnaire (53

resources: 23 material, 18 human and 12 pharmaceutical) and a consensus round. We performed descriptive analyses for both panels.

Seventeen PHEs and 16 clinicians from nine and four countries respectively participated in the study. Consensus between the two panels was observed on 40 resources (16 material, 14 human, 10 pharmaceutical; 33 included and seven rejected). Notably, clinicians selected three home care resources while PHEs did not, and PHEs included two pharmaceutical resources which clinicians did not. No consensus was observed on 13 resources. Eleven additional resources were suggested (five by PHEs and six by clinicians) and included amongst which personal protective equipment for mobile teams, resources for primary care and resources related to mechanical ventilation.

There was consensus on 40 resources, of which 33 were included and seven rejected. There was no consensus on 13 resources, notably regarding home care and pharmaceutical resources, which reflects the different priorities of PHEs and clinicians in pandemic planning. This study highlights a set of resources to prioritize for pandemic preparedness activities, and shows the importance of including experts from varied backgrounds. Including these resources in pandemic models and preparedness exercise scenarios allows training on resource gaps and supports evidence-based decision making during future outbreaks.

Supporting rurally dwelling adults with disabilities: the experiences of two organisations in Western Australia during the COVID-19 pandemic

Zoe Lawrence-Haughey¹, Monica Moran², Barbara Nattabi¹, Rohan Rasiah²

¹The University of Western Australia, Australia, ²The Western Australian Centre for Rural Health, Australia

Background and Objective: The COVID-19 pandemic disproportionately impacted people with disability and people living in rural areas, worsening existing inequalities. Many people with disability in Australia are assisted by disability support workers (DSWs) and disability support organisations (DSOs), though there has been little research done on how DSWs and DSOs have been affected by COVID-19. The aim of our study was to explore the experiences of staff from two rural DSOs in a large rural town in Western Australia (WA) who supported adults with disability during the COVID-19 pandemic and determine what challenges and opportunities they faced during this time.

Methods: Eleven employees from two DSOs in Western Australia were recruited mid-2022 using non-random purposive sampling. Three individual and two group semi-structured in-depth interviews were conducted via video-call software and reflexive thematic analysis was used in data analysis.

Results: Four major themes were identified. The study revealed that there were difficulties with the government pandemic response, increasingly unclear work boundaries for DSWs, and a high burden of the pandemic on DSOs, though organisations and employees adapted as best they could. Participants raised concerns over a perceived lack of inclusion of the disability sector and people with disability during the pandemic.

Conclusion: Whilst DSOs and DSWs believe that they have been able to maintain supports for clients during the pandemic, the lack of systematic public health approach for people with disability was evident. Future pandemic response in Australia requires consultation with the disability sector, utilisation of appropriate communication channels, and improved advocacy services for people with disability.

Zeno, 35-37, 56123 Pisa, Italy, ⁴University of Pisa, Department of Biology, Via S. Zeno, 35-37, 56123 Pisa, Italy, ⁵University of Pisa, Department of clinical and Experimental Medicine, Via Roma, 67, Pisa, Italy, ⁶University of Pisa, Department of Chemistry and Industrial Chemistry, Via Moruzzi, 3 - Pisa, Italy

Background and Objectives: The epidemiological relevance of viral acute respiratory infections (VARIs) has been dramatically highlighted by COVID19, but other viruses cannot be neglected, such as influenza virus, respiratory syncytial virus, rhinovirus, other coronavirus, adenovirus, metapneumovirus. The transmission of these viruses occurs mainly in closed spaces and is dependent both on human and environmental factors. Besides schools, closed communities, such as nursing homes and prisons are the most vulnerable settings, where the real extent of VARIs is often difficult to evaluate, due to the natural history of the diseases and to case ascertainment. In the COVID19 pandemic the Wastewater Based surveillance has shown its great potential for monitoring the virus diffusion and evolution in the environment. Our aim is to pilot an integrated surveillance system for closed communities, carried out through a syndromic surveillance, environmental monitoring (air, surfaces, and wastewater), and the collection on environmental and behavioral risk factors.

Methods: The Project funded by the National Recovery and Resilience Plan NRRP - Tuscany Health Ecosystem will consists in design and validate tools for epidemiological and environmental surveillance and analytical methods for environmental matrices, including viral sensors for viruses detection. The integration of all these information into risk assessment models will provide a useful tool for early warning and risk management.

Results: In the first phase of the project we will design and validate tools, such as clinical, epidemiological and environmental-based questionnaires, for each setting coupled with analytical methods for viruses' detection. The integrated surveillance system for closed communities, will be carry-out through syndromic surveillance, environmental monitoring (air, surfaces, and wastewater) and collection of environmental risk factors.

Conclusion: Integrating different surveillance systems for VARIs appears crucial to inform early warning and risk assessment tools available at local, regional and National level, but methods and strategies need to be set up.

¹Università Cattolica del Sacro Cuore, Italy

Background and Objective: The spread of COVID-19 in indoor environments is a critical concern during the ongoing pandemic and mathematical modelling can provide insight into the transmission of SARS-CoV-2 in these settings. However, input factors used in these models have not been clearly described or analysed. The objective of this work was to retrieve and report the parameters related to the biological characteristics of SARS-CoV-2 and the physical parameters of the indoor environment that are used in the mathematical modelling of infectious disease transmission in indoor environments.

This research was conducted within the framework of the national "Optimal bEhavior iN paNdEmic Scenario" (OPENNESS) project, funded by Regione Lazio. **Methods:** We searched the PubMed database up to 31/11/2022 for English-language articles on quantitative risk assessment of indoor transmission of COVID-19.

Articles addressing other infections or including outdoor-developing diseases were excluded.

Results: The research generated 110 outputs, of which 2 studies were retained. One study employed a deterministic approach, while the other adopted a probabilistic mathematical method.

The common parameters identified in the two studies were: the pathogen quanta emission rate, exposure to quanta concentration, number of quanta received by an exposed susceptible person, time-dependent particle number concentration, and deposition of particles in the host's respiratory system.

The deterministic model better predicts particle filtration and deposition into receptor respiratory systems, whereas the probabilistic model provides more accurate results in environmental conditions with less clearly specified parameters. **Conclusion:** The parameters identified in this review and their subsequent analysis lay the groundwork for future research on the mathematical modelling of SARS-CoV-2 indoor transmission. More research is needed to understand better the role of these parameters to validate and refine existing mathematical models, in order to inform public health decision-making and prevent COVID-19 from spreading in indoor environments.

An assessment on the interplay of digital proximity app use and vaccine uptake for SARS-CoV-2 transmission mitigation in

Switzerland

Paola Danio¹, André Moser², Marc Höglinger³, Nicole Probst Hensch⁴, Medea Imboden⁴, Thomas Verme⁴, Dirk Keidel⁴, Murielle Bochud⁵, Natalia Ortega Herrero², Stéphanie Baggio², Patricia Chocano-Bedoya², Nicolas Rodondi⁶, Stefano Tancredi⁷, Cornelia Wagner⁷, Stéphane Cullati⁷, Silvia Stringhini⁸, Semira Gonseth Nusslé⁹, Caroline Veys-Takeuchi⁹, Claire Zuppinger⁹, Erika Harju¹⁰, Gisela Michel¹⁰, Irène Frank¹¹, Christian Kahlert¹², Emiliano Albanese¹³, Luca Crivelli¹³, Sara Levati¹³, Rebecca Amati¹³, Marco Kaufmann¹⁴, Marco Geigges¹⁴, Tala Ballouz¹⁴, Anja Frei¹⁴, Jan Fehr¹⁴, Viktor von Wyl¹⁴

¹University of Zurich, Institute for Implementation Science in Health Care, Switzerland, ²University of Bern, ³Winterthur Institute of Health Economics, Switzerland, ⁴Swiss Tropical and Public Health Institute, Switzerland, ⁵University of Basel, Switzerland, ⁶Bern University Hospitals, Switzerland, ⁷University of Fribourg, Switzerland, ⁸University of Geneva, Switzerland, ⁹University of Lausanne, Switzerland, ¹⁰University of Lucerne, Switzerland, ¹¹Lucerne Cantonal Hospital, Switzerland, ¹²Cantonal Hospital St. Gallen, Switzerland, ¹³Università della Svizzera Italiana, Switzerland, ¹⁴University of Zurich, Switzerland

Background and Objective: During the first year of the SARS-CoV-2 pandemic, digital proximity tracing apps were introduced to mitigate viral spread in absence of vaccines. Adherence to such measures leading up to and following widespread vaccine rollout remains unclear. Our study aimed to evaluate adherence to digital proximity tracing app use and preventive measures across different vaccination uptake trends.

Methods: We report findings from two population-based longitudinal cohorts in Switzerland from January to December 2021. Failure time analyses were conducted for each study cohort for SARS-CoV-2 vaccine uptake and uninstalling of the SwissCOVID digital proximity tracing app outcomes, stratified by age group. Cox proportional hazards regression models were used to estimate adjusted hazard ratios (aHR). The analyses assessed the primary outcomes and associations with other actions taken by individuals to reduce viral spread (e.g., getting tested for SARS-CoV-2).

Results: We included 4514 participants from the Corona Immunitas Digital Follow-up (CI-DFU) and 1969 participants from the COVID-19 Social Monitor (CSM) studies. We observed a trend of individuals who did not adhere SwissCOVID app use and did not get vaccinated during the study period. We found an increased uptake of the vaccine associated with SwissCOVID app use (aHR, 1.51; 95% CI: 1.40-1.62 [CI-DFU]; aHR, 1.79; 95% CI: 1.62-1.99 [CSM]) or adherence to preventive measures (aHR, 1.44; 95% CI: 1.28-1.62 [CI-DFU]; aHR, 1.82; 95% CI: 1.52-2.18 [CSM]). Decreased SwissCOVID uninstallation risk was observed for participants who got vaccinated (aHR, 0.55; 95% CI: 0.38-0.81 [CI-DFU]; aHR, 0.45; 95% CI: 0.27-0.78 [CSM]).

Conclusions: We found strong evidence that adherence to digital proximity tracing app use and preventive measures is associated with higher vaccine uptake. In evolving pandemic contexts, these findings can assist public health authorities in designing evidence-based communication strategies to enable adoption of preventive measures and novel health technologies across all population groups.

Opinions matter: public opinions on data-sharing and how they can shape pathogen genomic surveillance in Canada

Tian Rabbani¹, Sarah A. Savić Kallesøe^{1,2}, Erin E. Gill³, Fiona S.L. Brinkman³, Emma J. Griffiths¹, Ma'n H. Zawati⁴, Hanshi Liu⁴, Nicole Palmour⁴, Yann Joly⁴, William W.L. Hsiao¹

¹Faculty of Health Sciences, Simon Fraser University, Burnaby, Canada, ²Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom, ³Department of Molecular Biology and Biochemistry, Simon Fraser University, Burnaby, Canada, ⁴Department of Human Genetics, McGill University Faculty of Medicine and Health Sciences, Montreal, Canada

Background and Objective: Intersections of public health and pathogen genomics have played a vital role in surveilling the Coronavirus Disease 2019 (COVID-19) pandemic and building resilient health systems. Individual-level COVID-19 data collected by Canadian provincial/territorial health authorities is not yet readily available to the public, including researchers. Lack of data-sharing delays or prohibits national data interpretation, harmonization, integration, and surveillance. To inform pathogen genomic-based surveillance practice and research innovation, (e.g. virusseq-dataportal.ca [1]; covarnet.ca [2]), we explored public opinions on sharing de-identified COVID-19 data publicly in Canada.

Methods: In March 2022, a national survey was open to those 18 years or older and currently living in Canada. Opinions on publicly sharing 16 de-identified COVID-19

datatypes (i.e. data removed of identifiable information such as name, birthday, etc.) were assessed.

Results: Of 4,981 participants, 79.7% were supportive of publicly sharing de-identified COVID-19 data, whilst 20.3% were hesitant/averse/unsure. Participants most supported sharing symptoms (83.0% in support), region (82.6%), and COVID-19 vaccination status (81.7%). Participants were most averse to sharing their employment sector (27.4% averse), postal area (26.7%), and international travel history (19.7%). Generally supportive participants were characterized as being age 50 years or older, with higher education, and at least singly vaccinated against COVID-19. Vaccination status was the most influential predictor of data-sharing opinion. Participants who were ever vaccinated were 4.20 times more likely (95% CI, 3.21-5.48, PLinks:-----[1] <https://virusseq-dataportal.ca/>[2] <https://covarnet.ca/>)

A review of the association between micronutrients and risk and severity of COVID-19

Parnian Jalili¹, Catherine Phillips¹

¹University College Dublin, School of public health, physiotherapy, and sports sciences, Woodview House, Belfield, UCD, Dublin4, Ireland

Introduction: The end of 2019 was marked by the rapid epidemic of Severe Acute Respiratory Syndrome (SARS) due to COVID-19 in Wuhan, China. The most common medical treatment pathways have been supportive rather curative. However, multiple studies have found impaired levels of micronutrients in patients. These associations with disease outcomes could be taken into consideration. Micronutrient deficiencies (MNDs) are a global health concern and an underdiagnosed epidemic highly affecting developing countries. The most vulnerable groups for MNDs are women, children, and the elderly. MNDs can cause a huge number of morbidities and mortalities indicating the significance of effective prevention and treatment strategies to further control the consequences. Objectives: The aim of this study was to review and summarise the literature on dietary intake and supplementation and the associations of micronutrient insufficiencies with disease susceptibility and severity of symptoms.

Methods: A narrative review of the literature was conducted through two online databases in PubMed and Google Scholar. Articles that were published since the start of the pandemic and had different types of study designs were included. Of 5,073 identified articles, 38 studies were selected according to defined inclusion criteria.

Results: The most prevalent nutritional insufficiencies and their associations with prevention and disease severity among COVID-19 patients were identified. Patients had impaired levels of a wide range of micronutrients, including vitamin D, Zinc, and Selenium followed by vitamins B1 and C.

Conclusion: Malnutrition and undernutrition are global concerns and modifiable risk factors in many countries impacting the prevalence of infectious diseases. Medical nutrition therapy (MNT) is an overarching method to combat nutritional deficiencies. Thus, alongside preventive measures like acquiring herd immunity by vaccination, achieving an optimal nutritional status could be a contributing factor for better outcomes in patients.

Knowledge, attitudes, practice of people toward the COVID-19 pandemics, and its impact in Afghanistan

Khawaja Saeed¹, Khawaja Saeed², Narges Niazi³, Khushal Nabizada⁴

¹AFETP EMPHNET, Afghanistan National Public Health Institute, Golayee Hese Awal Khair Khana, Afghanistan, ²MoPH, Afghanistan National Public Health Institute, Golayee Hese Awal Khair Khana, Afghanistan, ³WHO Kabul, ⁴Freelance, London UK, United Kingdom

COVID-19 pandemic disrupted the social and economic norms. Knowledge, Attitude and Practices studies are used to address the information gap for further strategic decision making to control the pandemic. This study aimed to find the level of Knowledge, Awareness, Attitudes, and behavioral practices of the people of Afghanistan about the COVID-19 and its impact on health and socio-economic dimension of their routine lives. We used a cross-sectional method with two stage sampling design. Data analysis was performed using SPSS v.20. The survey focused on adults including men and women all over the country to represent the country, including the urban and rural areas. Most of the respondents are in the age group of 21-30 years (46.5%); 60.15% of the participants are married. Almost 75% of females and 84% of males were literate and most participants have a bachelors degree (34%). More than 80% of participants knew they can prevent themselves from contacting COVID-19 through hand washing frequently with soap

and water and wearing a mask. More than 80% of participants responded that they would go for a lab test for detection of the virus as well as COVID-19 vaccination if it is available. Almost 35% reported always wearing a mask to prevent COVID-19 transmission; more than half of participants always wash their hands, more than 60% of them do not touch their eyes, nose, and mouth frequently. Nearly 60% of participants indicated that their household had problems satisfying food needs partly during the COVID-19 pandemic. Nearly half of participants believed that the government was successful in applying lockdown measures and in awareness rising (56.8 and 69.8%). The study findings provide some useful insight about the KAP of communities in Afghanistan, which could assist policy makers in public health to design and implement interventions based on the information gaps reported.

Inequalities in accessing COVID-19 vaccination: the findings from population-based survey in areas with high hesitancy

Deogratus Bintabara¹

¹The University of Dodoma, Department of Community Medicine, The University of Dodoma, Tanzania, P.O Box 259, Dodoma, Tanzania

Background and Objective: Inequality in accessing healthcare services is well-documented worldwide. However, little literature discussed the inequality in accessing COVID-19 vaccination. Furthermore, the spatial dimension of this inequality is largely unexplored in the literature. Therefore, this study examined the regional variation of educational-related inequality in accessing COVID-19 vaccination in Tanzania to identify populations with greater disadvantages.

Methods: The uptake of any complete dose of the COVID-19 vaccine was used to measure access to COVID-19 vaccination. The inequalities were assessed by using concentration curves and concentration indices (CI). The multivariable logistic regression was performed to identify the potential contributors to the inequalities in accessing COVID-19 vaccination.

Results: A total of 22910 adults from four major cities in Tanzania were interviewed. About 20% of the respondents received the COVID-19 vaccine. The highest educational-related inequality in accessing COVID-19 was in favor of educated compared to uneducated adults. After disintegration by regions, the high extent of inequalities was observed among adults in Mwanza (CI: 0.093, P<0.001) and Arusha (CI: 0.062, P<0.001) compared to Iringa (CI: 0.011, P<0.05) and Morogoro (CI: 0.040, P<0.001) regions. The contributors to inequalities in accessing COVID-19 vaccinations were age, sex, marital status, and occupation. Conclusion: The current study is the first to investigate the regional variation of inequality in the COVID-19 vaccination in areas with high hesitancy. Establishing policies or strategies which will consider regional variations in educational inequality might be a way forward toward achieving universal coverage of COVID-19 vaccination, especially in areas with high hesitancy.

Health-related quality of life among long-COVID patients - Tunisia, 2020-2022

Sonia Dhaouadi¹, Mouna Safer¹, Letaief Hejer¹, Aicha Hechaichi¹, Hind Bouguerra¹, Amenallah Zouayti¹, Chaima Aichouch¹, Arwa Neffati¹, Myriam Bougatef¹, Nawel El Mili¹, Rim Mhadhbi¹, Khouloud Talmoudi¹, Nissaf Bouafif ép Ben Alaya¹

¹National Observatory of New and Emerging Diseases, Tunis, Tunisia

Introduction: Coronavirus disease 2019 (COVID-19) has become a global health threat not only because of its acute phase, but because of the "long-COVID" that cause a substantial disease burden.

Long-covid include also long-term consequences affecting patients' wellness and quality of life.

Our study aimed to assess the impact of long-covid on the patients' quality of life in Tunisia.

Methods: We conducted a cross sectional retrospective survey among a representative sample of COVID-19 survivors in Tunisia registered at the national SARS-Cov-2 surveillance database from September 2020 to September 2021.

Trained health care workers interviewed consenting respondents by phone using a standardized questionnaire (EQ-5D-3L) including five dimensions: mobility, self-care, usual activities, pain-discomfort and anxiety-depression. Each dimension has three levels: no problem; some problem and extreme problems.

Respondents recorded their perceived quality of life on a visual analog scale VAS (0-100).

Alpha Cronbach was used to measure internal reliability of questionnaire's item. We compared health-related quality of life between two groups: with and without

long-covid.

Results: Of 1094 persons contacted, 416 responded (38%).

Long-covid prevalence was 64% (95%CI:59%-69%):128 (31%) of participants reported any problem in all dimensions: 41% among long-covid patients vs 13% among non-long covid ($p<10^{-3}$).

Compared to non-long covid patients, long-covid patients reported more problem on all dimensions: mobility: 14.8% vs 4.1% ($p=10^{-3}$), usual activity: 12.6% vs 4.8% ($p=0.01$), pain-discomfort: 22.4% vs 3.4% ($p<10^{-3}$) and anxiety-depression: 19.8% vs 8.1% ($p=0.002$).

The VAS was significantly lower among long-covid patients compared to non-long covid: 73.1 vs 83.9 ($p<10^{-3}$).

Alpha Cronbach's value was 0.66.

Conclusion: Long-covid impact quality of life, affect mobility and cause disability. Psychological support during and after acute COVID-19 episode is recommended to preserve the well-being of affected patients. This additional burden shows the importance of the public health prevention measures and vaccine strategies.

Reception and healthcare services for marginalised and undocumented migrants face the challenge of COVID-19

Achille Cernigliaro¹, Silvia Pilutti², Enea Delfino², Marianna Parisotto³, Leonardo Mammana³, Silvia Giaimo³, Giulietta Balestra³, Raffaella Rusciani⁴, Delia Da Mosto³, Nicola Caranci⁵, Chiara Di Girolamo⁶, Elisa Adami³, Francesca Cacciatori³, Marianna Bettinzoli³, Roberto Di Monaco⁷, Stefania D'amato⁸, Teresa Spadea⁴

¹Department of Health Services and Epidemiological Observatory, Health Authority, Sicily Region 2) Complex Unit of Clinical Pathology, Department of Radiological Sciences and Services, Sant'Antonio Abate Hospital, Health Authority, Palermo, Trapani Province, Trapani, Italy, ²Prospettive ricerca socio economica sas, via Bernardino Galliani 10 bis, 10125, Turin, Italy,

³Centre for International & Intercultural Health - APS, Via di Corticella 303/3, 40128, Bologna, Italy, ⁴Epidemiology Unit, ASL TO3 Piedmont Region, Via Sabaudia, 164, 10095 Grugliasco (TO), Italy, ⁵Regional Health and Social Care Agency, Emilia-Romagna Region, Viale Aldo Moro, 21, 40127 Bologna, Italy, ⁶University of Turin, Health and Social Care Agency Emilia-Romagna Region, University of Turin, Regione Gonzole 10, Orbassano (TO), Italy, ⁷University of Turin, Department of Cultures, Politics and Society, Lungo Dora Siena 100, Turin, Italy, ⁸Ministry of Health, Directorate-General for Prevention, 00144 Rome, Italy

Background and Objectives: There is scant evidence on the direct and indirect impact of COVID-19 on undocumented migrants living in Italy. Therefore, a qualitative study was conducted in two Northern-Italy Regions (Piedmont and Emilia Romagna).

Methods: The research consisted of 10 focus groups and 37 semi-structured interviews, with professionals of public and private social services who work in the reception and healthcare system, and the latter with the migrants themselves, especially the undocumented.

Results: Lights and shadows emerge from the results.

Due to precarious housing and working conditions, migrants had a higher infection risk, however lockdown measures in reception facilities might have had a protecting role. The interruption of care pathways led to the worsening of health problems, although the contact with healthcare services for COVID-19-related issues permitted the diagnosis of previously unrecognised pathologies. Uncertainty, fear, social withdrawal, and the crisis of the migratory project increased mental pathologies/struggles. Furthermore, the loss of work, the increased burden in essential jobs, and the reduced protection of undocumented migrants led to further impoverishment and, consequently, increased health risks. Migrants highlighted the importance of the effects of the COVID-19 pandemic on the social determinants of health, especially on working and housing conditions, rather than directly on health.

Conclusions: Despite the initial impossibility of accessing health and social reception services, due to the lockdown, and the lack of specific operating protocols to manage undocumented migrants and, more broadly, marginalised communities, both public and private social sectors, and the community have activated proactive outreach actions towards migrants, in a logic of integration and subsidiarity. Under crisis conditions, social and health services have found the ability to reorganize themselves and adapt to the needs of these more fragile targets. How much of these efforts will be capitalized and "stabilized" in the post-pandemic?

Popul. Med. 2023;5(Supplement):A399

Post-acute COVID-19 syndrome in the workplace

Nicola Magnavita¹, Gabriele Arnesano², Igor Meraglia³, Marco Merella⁴

¹School of Occupational health, Università Cattolica del Sacro Cuore, Largo F. Vito 1, 00168 Roma, Ital, ²Occupational health, UCSC, Largo F. Vito 1, 00168 Roma, Italy, ³Occupational health, researcher, Largo F. Vito 1, 00168 Roma, Italy, ⁴Occupational Health, UCSC, Largo F. Vito 1, Italy

Background and Objectives: COVID-19 is a multi-organ disease that can cause a wide range of persistent symptoms following the initial acute infection. The health status of the workforce was examined as part of a health promotion program integrated into workplace medical surveillance.

Methods: In order to determine the prevalence of infection, stress, mental health issues, sleep problems, and work ability, 1378 workers exposed to occupational risks in the health and other sectors conducted a medical examination in addition to a questionnaire.

Results: In 2020 and 2021, 164 employees (or 11.6%) contracted COVID-19. Compared to other occupational sectors (7.4%), the frequency was higher among hospital employees (15%). 4 weeks after the infection had ended, 86% of the workers said that some symptoms were still present.

The infected employees exhibited similar levels of occupational stress and anxiety as the other employees, but they slept less soundly ($p=0.05$). In comparison to healthy respondents, Post-COVID workers showed lower levels of sleep quality, and higher levels of fatigue, anxiety, and depression ($p=0.001$). 1.3% of individuals stated that infections caused exacerbations of pre-existing diseases. These workers had a considerably lower working capacity ($p<0.001$) than other workers, in addition to the characteristics mentioned above.

Conclusions: As of December 13th, 2022, 654 million people worldwide have been infected with COVID-19 (<https://www.worldometers.info/coronavirus/>). Assuming a conservative estimate of 6.2% survivors who experience persistent symptoms, long-term effects of COVID-19 could have an impact on almost 40,500,000 people. It has been noted that long-term impacts could compound exponentially if this virus continues to spread among humans. Post-COVID employees need specialized disability management care.

DOI: 10.18332/popmed/163861

Analysis and management of the migrant population for covid19 emergency in the province of lecce

Alberto Fedele¹, Adele Idolo¹, Emanuela Civino¹, Giampaolo Mazzeo¹, Valerio Aprile¹

¹Local Health Authority, Lecce, Italy

Background and Objective: The COVID19 pandemic has been a significant risk factor for the health of migrant populations in Europe and Italy.

Objective study: investigate the epidemiology of COVID19 infection in the immigrant population arriving in Salento from 2020 to 2022.

Methods: Upon arrival, the COVID19 Surveillance Centre of ASL Lecce is activated. Migrants are hosted in dedicated Reception Centres, screened at time "0" by SARS-CoV-2 test and, in case of quarantine, at subsequent control test.

Sample: 4056 migrants welcomed to Salento between April 2020 and October 2022 with 81 arrivals.

Data stratified by gender, age, nationality were collected in a database and analyzed with MS-Excel.

Results: Study population: 90% males, 10% females. Average age 24 years, most represented age group 20-29 years (42%), 21% minors.

Most represented nationalities: Pakistan (26%), Iran (21%), Iraq (15%), Afghanistan and Egypt (11%).

7% of migrants (266) were positive (92% males, 8% females), average age 25 years, most represented age group 20-29 years (49%), 16% minors.

In 2020 9% were positive, in 2021 7% and in 2022 only 2%, with an average of positive for landing of 5%. Positive migrants came mainly from Pakistan (45%), Iran (10%), Bangladesh (9%); ethnic observation shows a higher rate of positivity among Bangladeshi citizens (21%).

All positive subjects showed mild symptoms, only 2 hospitalized and no deaths.

Conclusion: The data seem to confirm that young age and lack of comorbidity in immigrant population (healthy migrant) represent protective factors for SARS-CoV-2 infection and complications (hospitalization/deaths), despite the precarious social and health conditions.

The COVID19 surveillance system has highlighted the importance for Public Health, to increase attention to the most vulnerable migrant populations, to control and contain the spread of the virus, in particular in the reception facilities, including strengthening vaccination policies and health promotion initiatives and prevention measures.

The assistance GAPS in the struggle against covid-19 in Brazil: the temporal course in the beginning of vaccination of indigenous and quilombolas peoplesRafael Moreira¹, Lucas Santos², Tainá Mafrá², Herika Maurício³¹Oswaldo Cruz Foundation and UFPE, ABRASCO, Av. Professor Moraes Rego, s/n - Cidade Universitária - Recife/PE . CEP 50.740-465., Brazil, ²Oswaldo Cruz Foundation, Av. Professor Moraes Rego, s/n - Cidade Universitária - Recife/PE . CEP 50.740-465., Brazil, ³Universidade de Pernambuco, ABRASCO, Rua Arnóbio Marques, 310 - Santo Amaro, Recife/PE CEP: 50100-130, Brazil**Background/Objective:** With the pandemic of covid-19, the infection rate grew rapidly in Brazil, ranking among the countries with the highest cases and death rates. The national vaccination began in January 2021, focused on priority groups, including indigenous peoples and quilombolas, given their social vulnerability and difficulties in accessing health services. This study aimed to analyze the temporal evolution of vaccination against covid-19 in indigenous peoples and quilombolas in Brazil between the 3rd and 21st Epidemiological Week (EW) of 2021.**Methods:** A temporal analysis comprising 19 EW was performed. Cases were structured by priority group of indigenous and quilombola populations, dose, vaccine (Coronavac or Astrazeneca), and place of vaccination. The Vaccination Rate (VR) per 100 inhabitants was calculated. Temporal analysis of VR identified significant trends ($\leq 5\%$), and results were converted into temporal cluster graphs by EW.**Results:** By the end of May 2021, 1,176,173 doses of Astrazeneca (AZ) or Coronavac (CV) Vaccines had been administered to indigenous peoples and quilombolas. Nationally, 21.7% of CV and 99% of AZ vaccination schedules were incomplete for this priority group. The temporal analysis identified high VR of the CV first and second dose in the first weeks (EW 1 to 7), with a significant drop in subsequent weeks; and high VR of both doses of AZ concentrated in the final weeks (10 to 19).**Conclusion:** The indigenous and quilombola populations had low vaccination rates nationally. It is important to consider the decrease in CV vaccine in the analyzed period, highlighting that from May onwards the AZ vaccine distribution was predominant due to a decrease in the CV national production. Possible

factors contributing to the reduction of VR in these populations were poor access to health services; inconsistent national vaccination plan; geographical barriers; and hesitancy to vaccinate as a consequence of the spread of fake news.

DOI: 10.18332/popmed/163926

Evidence-based comparison on COVID-19 pandemic control strategies--Taiwan as an exampleShu-Ti Chiou¹¹Health & Sustainable Development Foundation, Taiwan**Background and Objective:** Taiwan was predicted to bear high risk of COVID-19 importation at the beginning of 2020. The author examined available evidence to explore what made Taiwan perform well in 2020, fix its breach in 2021, and overtake the other forerunners in 2022.**Methods:** Pandemic control strategies were categorized into 3 types- elimination, suppression and mitigation. Annual COVID-19 mortality rate, annual excess deaths and Google community mobility trend were used as impact indicators. Cumulative vaccination coverage rate was used to indicate preparedness, and tests per 1000 per day and stringency index in different periods were used to compare public health input.**Results:** In 2020, Taiwan applied swift and strict elimination strategy. At a population size of 23 million, there were only 802 confirmed COVID-19 cases, 7 deaths, and 253 consecutive days with 0 domestic case in 2020.

In 2021, a significant breach pushed the daily incidence close to that of UK at the same period, but Taiwan maintained its elimination strategy and eventually returned to zero though it took 3 months with inadequate testing capacity and refusal to lockdown.

In 2022, Taiwan cleaned up several Omicron breaches with only 3 deaths by March 31. However, it suddenly announced returning to normalcy with the "New Taiwan Model" on April 1. The daily incidence grew explosively and by November 26, its annual cumulative mortality rate has exceeded most of the other countries.

Conclusion: By cross-sectional comparison between countries and before-after comparison of the same country, the study shows that community activities were least restricted under elimination, and mitigation was consistently associated with hundred times higher health impact but didn't bring about normalcy in daily lives when incidence was high. Some countries managed to keep weekly excess death rate within 20% after abandoning elimination, but not Taiwan.

DOI: 10.18332/popmed/163929

Comparative analysis of maternal mortality in Central Asia region before and during COVID-19 pandemicKarina Nukeshtayeva¹, Olzhas Zhamantayev¹, Zhanerke Bolatova¹, Gaukhar Kayupova¹, Nurbek Yerdosov¹¹Karaganda Medical University, Kazakhstan**Background and Objective:** The maternal mortality ratio (MMR) is the key indicator that characterizes the state of a healthcare system. Various countries reports indicate a significant impact of the COVID-19 pandemic on MMR. We aimed to determine MMR trends in Central Asia (CA) countries and its association with the total health expenditures before and after pandemic. We also compared the maternal mortality causes before and during the pandemic in Kazakhstan.**Methods:** We conducted a retrospective study working with the secondary data which were collected on selected health indicators using information from open sources, and official statistical data on the Republic of Kazakhstan, Republic of Kyrgyzstan, Republic of Uzbekistan, and Tajikistan.

We applied the linear regression analysis to identify statistically significant trends of MMR in CA countries from 2000 to 2020 in the study. Pearson correlation analysis was used to assess the associations between the national MMR and CA total health expenditures expressed in national currency units. R-studio software version 1.2.5033 was used for the statistical analysis.

Results: During the pre-pandemic period, Central Asian nations had a downward trend of maternal mortality. Except for Uzbekistan, where this indicator decreased, all Central Asia countries experienced a sharp increase in maternal mortality ratio in 2020. The share of indirect causes of maternal deaths in Kazakhstan reached 76.3% in 2020. There is an association between the maternal mortality ratio in Central Asia countries and their total health expenditures expressed in national currency units ($r_{\max} = -0.89$ and $r_{\min} = -0.66$, $p < 0.01$).**Conclusion:** The COVID-19 pandemic has noticeably impacted the maternal mortality levels in most of the CA countries. The findings suggest that there must be additional efforts from the local authorities to enhance the preparedness of CA healthcare systems for the new public health challenges and improve health data accessibility.

Lessons learned from coronavirus disease: India's preparedness and response strategies for future pandemic

Soumya Mohapatra¹, Ramesh Sethi¹

¹Kalinga Institute of Industrial Technology (KIIT), Deemed to be University, Bhubaneswar, India

Background: The coronavirus disease (COVID-19) pandemic has impacted all nation-states and globally 66.34 lakhs deaths had been recorded whereas India has contributed 5.30 lakhs of deaths (as on 13th December, 2022 WHO). It has exposed persistent inequalities in demographic indicators across territorial boundaries along with structural and social issues like interconnected threats to population health and well-being rooted in socio-economic-political and physical environmental determinants of health. While developed nations had to face tremendous challenges related to overstretched capacity and fragmentation, developing nation's weak health provisions jeopardized its health delivery system and disrupted millions of lives and livelihoods.

Objective: To learn lessons from COVID-19 pandemic across the globe and fostering an enabling ecosystem with multi-sectoral integrative efforts to strengthen preparedness and response strategies to meet future pandemic.

Methods: The study synthesizes on available evidence based on secondary sources of data and focuses on both qualitative and quantitative methods.

Results: The study reveals pandemic trajectory of India witnessed slow and sustained decline of COVID-19 cases. India's strong and decisive leadership, proactive top-down approach, inter-sectoral coordination, massive vaccination drive and timely guidance for national response to the pandemic helped in reducing its cases and deaths per million to 25,158 cases per million and 345 deaths per million population respectively (as on 17th December, 2021) which is one of the lowest in the world. This indicates lessons learned from worldwide supported India to rebuild more resilience health care system and accelerate towards achieving global goals.

Conclusion: Healthcare system in most of the countries have not evolved for resilience in times of catastrophe. and also not for efficient rapid responses to pandemic. However, the countries undergone unprecedented health crisis have learnt lessons from COVID-19 which recommends the healthcare institutions need to be streamlined and instituted for increasing efficiency, coherence, and preparedness to prevent future pandemic.

A low burden of severe illness: the COVID-19 Omicron outbreak in the remote Torres and Cape region of Far North Queensland, Australia

Johanna Neville¹, Caroline Taunton¹, Leanne Hawthorn¹, Rittia Mattysek¹, Marlow Coates¹, Emma Pickering¹, Valmay Fisher¹, Allison Hempenstall¹, Simon Smith², Josh Hanson²

¹Torres and Cape Hospital and Health Service, Nil, L3/120 Bunda street, Carins 4870, Queensland, Australia, ²Cairns Hinterland Hospital Service, Australia

The arrival of the highly transmissible Omicron variant reignited concerns that outbreaks of COVID-19 could have devastating consequences for First Nations Australians living in remote areas. The Far North Queensland region of Australia is home to 19,500 First Nations people (68.8% of population). To prepare for a COVID-19 outbreak, Torres and Cape Hospital and Health Service TCHHS in partnership with local First Nations councils undertook extensive outbreak preparation including the establishment of a COVID-19 public health team and the delivery of a logistically complex outreach vaccination service. The first outbreak was declared in December 2021. Here we report local outbreak epidemiology for the first ten-month outbreak period from December 2021 to October 2022.

Outreach vaccination and walk-in fever clinics were established at 28 health facilities with 12 utilising point-of-care PCR machines. The public health team contacted cases by telephone throughout the period to undertake health screening; offer medical certificates; provide information about case isolation and close contact quarantine requirements; triage cases for treatment eligibility; and offer participation in the COVID-19 care-in-the-home program which provided wellbeing support telephone calls throughout mandatory isolation.

COVID-19 vaccination rates among those aged ≥ 12 years climbed from 43.4% to 79.3% (single dose) and from 22.2% to 67.6% (double dose) between early September and late December 2021. A total of 7784 cases were notified, with 65.5% of cases among First Nations people. The attack rate was 25.6% (95%CI 25.1%-26.1%), the hospitalisation rate was 1.6% (95%CI 1.3%-1.9%) and the crude

case fatality rate was 0.05% (95%CI 0.01%-0.13%). Genomic results were available for 213 specimens, with all (100%) identified as the Omicron variant.

We attribute the excellent outcomes to the mild Omicron variant and vaccination coverage along with local community leadership, strong partnerships, community engagement in testing and isolation, and community participation in the culturally considered COVID-19 care-in-the-home program.

Crossing the border: Adherence to the Vaccination Campaign in multicultural provinces of South-Tyrol during COVID-19 Pandemic, a cross-sectional study

Francesco Uguzzoni¹, Lucia Palandri², Antonio Lorenzon¹, Catalina Cristoforo³, Filippo Lozza³, Riccardo Poluzzi³, Maria Scasserra¹, Cristiana Rizzi¹, Pierpaolo Bertoli⁴, Florian Zerzer⁵, Elena Righi¹

¹University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy, Via Campi 287, 41125 Modena(MO), Italy, ²University of Modena and Reggio Emilia, ³South Tyrol Health Care Service, Epidemiological Surveillance Unit, Via Lorenz Böhler 5, 39100, Bolzano, Italy, ⁴South Tyrol Health Care Service, Medical Management, Via Lorenz Böhler 5, 39100, Bolzano, Italy, ⁵South Tyrol Health Care Service, General Management, Via Thomas Alva Edison 10/D, 39100, Bolzano, Italy

Objectives and Background: "South-Tyrol" Alpine region in Italy is administered as an "autonomous statute region", bordering Austria. This geographically heterogeneous environment is divided in 20 districts and is inhabited by a unique multicultural population. Poor evidence exists on factors influencing adherence to vaccination in peculiar contexts, therefore

The aim of this study was to investigate the role played by geographical, cultural and socio-demographical characteristics on COVID-19 vaccination adherence during the first year of the Italian vaccination campaign.

Methods: We carried out an ecological study by analysing data collected from each district of South-Tyrol: altitude, population density, linguistic belonging, Austrian border proximity, cultural heritage, winter tourism, COVID-19 incidence, complete primary vaccination cycle and booster dose. Data refer to February 2022, one year after the beginning of the vaccination campaign. Spearman correlation, Kruskal-Wallis and Mann-Whitney-U tests were performed to assess relationships between variables.

Results: On February 2022 district percentages of vaccination adherence varied widely ranging between 57.1% and 74.8%. Adherence to vaccination appears to be negatively correlated to altitude ($Rho = -0.626$, $p = 0.003$; $Rho = -0.693$, $p < 0.001$, respectively for primary vaccination and booster dose) and positively correlated to population density ($Rho = 0.585$, $p = 0.007$; $Rho = 0.600$, $p = 0.005$). Furthermore, primary vaccination appeared significantly lower in districts with a higher prevalence of German speaking population (69.2% vs 74.7%, $p < 0.05$) and in those more isolated or with a prevalent German cultural heritage.

Conclusion: In analysing vaccination adherence, diversity in geographic, demographic and cultural factors should be taken in great account, even when the target population appears homogeneous from a clinical standpoint and overall adherence to vaccination campaign is satisfying. To plan a more effective and homogeneous vaccination campaign, specific public health interventions more focused on cultural heritage and geomorphological peculiarities should be considered and implemented for specific subpopulations and areas.

Cardiovascular and respiratory events following COVID-19 hospitalisation: a cohort study in Portuguese hospitals

Andreia Leite¹, Maria Brazão², Sofia Nóbrega², Maria Lobão³, Luísa Eça Guimarães⁴, Rita Moça⁴, Lélita Santos⁵, Joana Paixão⁵, Helena Rodrigues⁵, Ana Ramalho⁵, Inês Simões⁶, Andreia Costa⁷, Gabriel Atanásio⁸

¹NOVA National School of Public Health, Portugal, ²Hospital Central do Funchal, Portugal, ³Hospital de Cascais, ⁴Centro Hospitalar Póvoa de Varzim-Vila do Conde, Portugal, ⁵Centro Hospitalar e Universitário de Coimbra, Portugal, ⁶Hospital Terras do Infante, Portugal, ⁷Centro Hospitalar de Trás-os-Montes e Alto Douro, Portugal, ⁸Centro Hospitalar Tondela/Viseu, Portugal

Background and Objective: Several studies have shown an increased frequency of cardiovascular and respiratory events, a part of the long COVID presentation. We aimed to describe the incidence of pre-specified cardiovascular and respiratory events after a COVID-19 hospitalisation.

Methods: We retrospectively collected data from individuals hospitalised due to

COVID-19 between March 2020 and March 2021 in six Portuguese hospitals. The cardiovascular events considered were: heart failure, myocarditis, arrhythmia, acute myocardial infarction, deep vein thrombosis, ischemic stroke, and hemorrhagic heart attack; and the respiratory events considered were: pulmonary thromboembolism, pulmonary fibrosis, chronic or prolonged respiratory failure, obstructive/restrictive lung disease, and organising pneumonia. We estimated incidence and 95% confidence intervals.

Results: Data collection is still ongoing. For this preliminary analysis, 1438 individuals were included. The median age was 70, 53% were male, and 12% died after hospital discharge. Individuals were in the study for a median of 17 months. Most individuals (66%) had moderate COVID-19, corresponding to supplementary oxygen use during hospitalisation, and 14% had severe COVID-19, needing ventilation or admission to ICU. During the study period, 98 cardiovascular and 85 respiratory events were registered, corresponding to an incidence of 3.5 (95% CI: 2.8; 4.3) and 3.9 (95% CI: 3.1; 4.9) cases per 1000 person-years, respectively. Overall, 172 events were registered, corresponding to an incidence of 107.9 (95% CI: 92.4; 125.3) cases per person-years. The incidence of cardiovascular and/or respiratory events increased according to the severity of the COVID-19 episode (mild – 75.7 (95% CI: 48.5; 112.6), moderate – 109.3 (95% CI: 90.1; 131.4) and severe – 143.9 (95% CI: 100.2; 200.1) cases per person-years, respectively).

Conclusion: Comparisons with the expected incidence rates in the absence of COVID-19 are required; nevertheless, our preliminary results indicate that the frequency of events increases with increasing COVID-19 severity.

The PHIRI project for measuring the impact of health crises on the European Healthcare System: the Italian case in COVID-19 pandemic

Andrea Faragalli¹, Eugenio Mattei², Martin Thissen³, Flavia Carle¹, Brigid Unim², Rosaria Gesuita¹, Ronan Lyons⁴, Sarah Aldridge⁴, Francisco Estupiñán-Romero⁵, Andrea Schmid⁶, Enrique Bernal-Delgado⁵, Luigi Palmieri²

¹Center of Epidemiology, Biostatistics and Medical Information Technology, Marche Polytechnic University, Italy, ²Department of Cardiovascular, Endocrine-metabolic Diseases and Aging, Istituto Superiore di Sanità-ISS, Rome, Italy, ³Department of Epidemiology and Health Reporting, Robert Koch Institute-RKI, Berlin, Germany, ⁴Swansea University Medical School, Swansea University, Swansea, United Kingdom, ⁵Data Science for Health Services and Policy Research Group, Institute for Health Sciences-IACS, Zaragoza, Spain, ⁶Austrian National Public Health Institute-GöG, Vienna, Austria

Background and Objective: The CoViD-19 pandemic brought out the need for a uniform European response to public health issues. With the purpose of assessing the impact of the pandemic on European Healthcare Systems, the European project Population Health Information Research Infrastructure-PHIRI (EC H2020-IBA-INFRA-CORONA-2020 n. 101018317), aims to create and implement a federated research infrastructure based on the secondary use of administrative health-care databases data and real-world data. First Italian results from the Istituto Superiore di Sanità-ISS and the Polytechnic University of Marche-UNIVPM are reported.

Methods: Four Use Cases (UC) were investigated. UC-A: Direct and indirect determinants of CoViD-19 infection on hospitalization of fragile populations (including heart attack and stroke (CVD), trauma, and hip and knee replacement surgery); UC-B: Delays in the treatment of breast cancer due to the pandemic; UC-C: Impact of CoViD-19 on perinatal health; UC-D: Changes in mental health status related to the CoViD-19 pandemic. PHIRI Research Centers developed and mutually shared the methodology, identified and processed the data necessary for the comparison between the pre (2017-19) and post (2020) pandemic periods using a Linux container (Docker). Docker allows sharing the analysis procedure, to perform it locally without any transfer of sensitive data, to produce structured results reports.

Results: In UC-A (ISS), 1,088,026 hospitalizations were identified in Italy in 2017-2019 (451,015 for CVD; 400,057 for prosthetic surgery; 236,954 for trauma) and 338,740 in 2020 (140,421; 117,483; 80,836, respectively). In UC-B (UNIVPM), 818 new breast cancer interventions were identified in the Marche region in 2020; 2,964 in 2017-2019. Median time from diagnosis to surgery in 2020 was 39 days (1st-3rd Q: 26-61), 39 days (1st -3rd Q: 24-56) in 2017-2019 (p =0.08).

Conclusions: Administrative health databases and real-world data in a federated research infrastructure can help European stakeholders to support shared decision-making in health crises.

Associations Between Reported Post-COVID-19 Symptoms and

Subjective Well-Being, Israel, July 2021 -April 2022

Paul Otiuk¹, Michael Edelstein¹, Yanay Gorelik¹, Amiel Dror¹, Hiba Zayyad², Ofir Wertheim², Kamal Abu Jabal³, Saleh Nazzal², Jelte Elsinga¹, Daniel Glikman¹, Michael Edelstein¹

¹Azrieli Faculty of Medicine, Bar-Ilan University, Israel, ²Baruch Padeh Hospital, Israel, ³Ziv Medical Centre, Israel

Background and Objective: Prolonged and persistent symptoms following acute SARS-CoV-2 infection has been widely reported, but the impact of individual symptoms reported post-COVID-19 on subjective well-being (SWB) is unknown. We described associations between SWB and selected reported symptoms following SARS-CoV-2 infection.

Methods: We analysed reported symptoms and subjective well-being from 2295 participants (of which 576 reported previous infection) in an ongoing longitudinal cohort study taking place in Israel, in which participants regularly report their health status. We measured SWB using the WHO-5 standardized tool and estimated changes in SWB associated with reported selected symptoms at three follow-up time points (3-6, 6-12, and 12-18 months post-infection) among participants reporting previous SARS-CoV-2 infection, adjusting for key demographic variables, using linear regression.

Results: Our results suggest that the biggest and most sustained changes in SWB stems from non-specific symptoms (fatigue -7.7 percentage points (pp), confusion/ lack of concentration -10.7 pp, and sleep disorders -11.5pp, p<0.005), whereas the effect of system-specific symptoms, such as musculoskeletal symptoms (weakness in muscles and muscle pain) on SWB, are less profound and more transient. Each symptom was individually associated with a decrease of SWB after adjusting for other symptoms.

Conclusion: Post-acute COVID19 symptoms can have a profound and lasting effect on well-being, especially among individuals experiencing several symptoms. Taking a similar approach for other symptoms and following individuals over time to describe trends in SWB changes attributable to specific symptoms will help understand the post-acute phase of COVID-19 and how it should be defined and better managed.

DOI: 10.18332/popmed/164010

Impact of COVID-19 Lockdowns on Gastrointestinal Cancer Incidence: A Registry-Based Study in Bavaria - Germany

Amir Hakimhashemi¹, Sven Voigtländer¹, Nina Grundmann¹, Martin Meyer¹, Jacqueline Müller-Nordhorn¹

¹Bavarian Cancer Registry, Bavarian Health and Food Safety Authority, Germany

Background and Objective: Recent scientific studies show that the COVID-19 pandemic affected the cancer screening programs and, consequently, cancer incidence in different countries worldwide. This study investigated the impact of the two lockdowns in March 21 to May 3, 2020 (first lockdown) and December 9, 2020 to March 7, 2021 (second lockdown), on gastrointestinal cancers (ICD-O-3: C15 – C26) in Bavaria, Germany.

Methods: We gathered incident cancer data including malignant and in situ cases from approximately 50% of pathological centres in Bavaria. We aggregated the number of incident gastrointestinal cancers in months stratified by cancer site and malignancy in pre-pandemic (03.2019 to 02.2020) and pandemic (03.2020 to 02.2021) periods. We estimated the relative changes of numbers of cancers between pandemic and pre-pandemic periods with corresponding confidence intervals using a Bonferroni correction (13 tests with $\alpha = 0.0038$).

Results: The number of malignant gastrointestinal cancers significantly declined from 10,587 in the pre-pandemic period to 9,749 in the pandemic period with a relative difference of -7.9% (95% CI: -11.6% to -4.1%). It significantly reduced for colon cancer from 4,032 to 3,568 (relative change: -11.5%; 95% CI: -17.2% to -5.4%) and rectum cancer from 2,095 to 1,772 (relative change: -15.4%; 95% CI: -23.0% to -7.1%). We found no significant reductions for other sites. The number of in situ cases decreased from 451 to 327 with a relative change of -27.5% (95% CI: -41.2% to -10.5%). It also declined in colon cancer from 281 to 170 cases (relative change: -39.5%; 95% CI: -54.3% to -19.9%), but not in the other sites.

Conclusion: The COVID-19 pandemic affected the number of pathological diagnoses of gastrointestinal cancers in Bavaria. The reduction was mainly due to the reduction in diagnoses of colon and rectum, which could be a result of decreases in screening cases during the lockdowns.

Popul. Med. 2023;5(Supplement):A412

DOI: 10.18332/popmed/164028

How were place of death trends for cancer patients affected by the COVID-19 pandemic? An international death certificate study

Silvia Lopes¹, Andrea Bruno de Sousa², Joachim Cohen³, Barbara Gomes¹
¹ENSP-NOVA NOVA National School of Public Health & Comprehensive Health Research Center & Faculty of Medicine, University of Coimbra Portugal, ²FMUC, ³VUB End-of-Life Care Research Group, Vrije Universiteit Brussel Belgium

Background and objective: During the pandemic, health systems had to respond to the needs of COVID-19 patients, while caring for patients with other conditions, including cancer. Hospitals/health institutions and home are relevant places of death (PoD) globally. We aim to examine changes in PoD trends for cancer patients, comparing pre- and pandemic years.

Methods: We sought national PoD data from vital registries of 47 countries varied in UN Regions. We describe the distribution of PoD (focused on hospital/health institution and home) for cancer patients [ICD-10 codes: C0-C97 (except C91-95)] from 2015 to 2021, examining variations by year, age (0-17 or ≥18) and country. Pandemic years include 2020 and, where available, 2021.

Results: Preliminary data shows that among 3,005,530 deceased from cancer (99.7% aged ≥18y) across 19 responding countries so far (15 countries providing 2021 data), home deaths increased in pandemic years (range per year: 40%-45%) compared to pre-pandemic (33%-35%). Inversely, deaths in hospitals/health institutions decreased (54%-56% to 43%-49%). Sub-analysis of the pediatric group (9,894 deceased) also showed increasing home death (32%-34% to 39%-39%). Consistently, for 18 out of the 19 countries the percentage of hospital/health institution deaths for cancer patients decreased during the pandemic (-11% in the country with largest decrease; smallest: -2%), while for 17 out of 19 countries the percentage of those dying at home increased (12% in country with largest increase; smallest: 1%).

Conclusion: An increase in home deaths appears to have occurred among cancer patients in the COVID-19 pandemic. A more detailed and homogeneous classification of PoD would provide stronger cross-country comparisons, as what is classified in each category varies. It is important to monitor if this shift in PoD is kept or reverts beyond 2021, due to the implications for the allocation of health resources to care for the dying.

Effectiveness of vaccination against SARS-CoV-2 infection in the pre-delta era: a systematic review and meta-analysis

Angela Meggioraro¹, Monica sane schepisi¹, Giovanni Rezza¹
¹Italian Ministry Of Health Italy

Background: The objective of this study was to assess the effectiveness of SARS-CoV-2 vaccines in terms of prevention of disease and transmission in the pre-Delta era. The evaluation was narrowed to two mRNA vaccines and two modified adenovirus-vectored vaccines.

Methods: The overall risk of any SARS-CoV-2 infection confirmed by positive real-time Polymerase Chain Reaction (PCR) test was estimated in partially and fully vaccinated individuals. The evidence synthesis was pursued through a random-effects meta-analysis. The effect size was expressed as relative risk (RR) and RRR (RR reduction) of SARS-CoV-2 infection following vaccination. Heterogeneity was investigated through a between-study heterogeneity analysis and a subgroup meta-analysis.

Results: The systematic review identified 27 studies eligible for the quantitative synthesis. Partially vaccinated individuals presented a RRR = 73% (95%CI = 59-83%) for positive SARS-CoV-2 PCR (RR = 0.27) and a RRR=79% (95%CI = 30-93%) for symptomatic SARS-CoV-2 PCR (RR = 0.21). Fully vaccinated individuals showed a RRR = 94% (95%CI = 88-98%) for SARS-CoV-2 positive PCR (RR = 0.06) compared to unvaccinated individuals. The full BNT162b2 vaccination protocol achieved a RRR = 84-94% against any SARS-CoV-2-positive PCR and a RRR = 68-84% against symptomatic positive PCR.

Conclusions: The meta-analysis results suggest that full vaccination might block transmission. In particular, the risk of SARS-CoV-2 infection appeared higher for non-B.1.1.7 variants and individuals aged ≥69 years. Considering the high level of heterogeneity, these findings must be taken with caution. Further research on SARS-CoV-2 vaccine effectiveness against emerging SARS-CoV-2 variants is encouraged.

²Department of Biomedical, Metabolic and Neural Sciences, Section of Public Health, University of Modena and Reggio Emilia, Modena, Italy,

³Laboratorio Analisi TEST Srl, Modena, Italy

Background and Objectives: The COVID-19 pandemic has hit worldwide. Italy was one of the first European countries to be severely affected. Many factors can play relevant roles in SARS-CoV-2 infection, both in virus replication and in activating the host's immune system. This case-control study aims to assess the possible relationship between SARS-CoV-2 infection, evaluated through antibody response and the main socio-demographic, occupational, clinical-anamnestic and biochemical factors, in a population mostly residing in the Modena province (northern Italy) and mainly composed of workers.

Methods: Enrolment was performed among subjects who voluntarily underwent serological testing. Subjects with antibody positivity for IgM and/or IgG (cases) and a similar number of negatives (controls), matched by sex, age and Italian region or foreign country of birth, were selected. Additional parameters (zinc/iron/copper/chromium/nickel, vitamins D/B12, folates, triglycerides, LDL/HDL/total cholesterol) were determined. Moreover, a questionnaire on the main relevant socio-demographic occupational and clinical data was administered through telephone interviews.

Results: A total of 405 subjects have been enrolled, 166 cases (mean age 50.6±12.4 years), 71 (42.8%) men and 95 (57.2%) women, and 239 controls (mean age 50.6±11.6 years), 106 (44.3%) men and 133 (55.7%) women. The smokers' percentage was significantly lower in cases (12.7%) compared to controls (20.6%). Among cases a higher percentage of subjects with diabetes (2.4% vs 0.8%) and a lower percentage of persons affected by respiratory diseases (9.7% vs 12.6%) were found. By analysing biochemical data, a lower median serum level of folates was detected among cases.

Conclusion: Our results suggest an inverse association of SARS-CoV-2 infection evaluated through antibody response with smoke and also with folates serum level. The first association, also observed in other studies, is controversial due to the role of potential confounding factors. Regarding the inverse association with folates, a recent study shows that folates bind and inactivate a viral protease.

Background: Several studies have shown that antibody responses in people with HIV depend on CD4 count and people with HIV with CD4 counts below 500 may have a weaker response to vaccination. This systematic review aims at evaluating vaccine effectiveness reported by real world studies on HIV patients.

Material and Methods: PubMed, medRxiv/bioRxiv, WHO covid-19 databases, the VIEW-hub platform and the 2022 CROI (Conference on Retroviruses and Opportunistic Infections) site were searched using the terms "COVID-19", "SARS-CoV-2", "vaccine efficacy", "people living with HIV".

Results: Real world studies were conducted in Zambia [3], Taiwan [4], South Africa [5], and the Russian Federation [6]. Vaccine effectiveness estimates ranges varied widely across included studies according to the outcome considered: - infection: 65,8 [6]- 100% [4] - severe disease/hospitalization/ICU admission: 73,2 - 79,3% [5] - death/in-hospital mortality: 67,2 [5] - 76,0 % [3] Vaccine effectiveness author outcome hiv+ Vaccinated hiv+ unvaccinated ve% 95CI events total %95CI events total %95CI gushchin infection 71 2543 2,3 (2,2 - 3,5) 1354 16606 8,2 (6,1 - 8,6) 65,8(56,7 -72,9) LIN infection 0 336 0(0 - 1,1) 37 2795 1,3 (0,9 - 1,8) 100 bekker hospitalization 18 3802 0,5(0,3 - 0,8) 66 3731 1,8 (1,4 - 2,3) 73,2(55,0-84,1) bekker ICU admission 4 3802 0,1 (0,0 -0,3) 19 3736 0,5(0,3 - 0,8) 79,3 (93,0-99,9) bekker death 5 3803 0,1 (0,0 -0,3) 15 3738 0,4 (0,2 - 0,6) 67,2 (9,9-88,1) hines in-hospital mortality 17 159 5,8(3,4 - 9,1) 295 1229 24,0(21,6 - 26,5) 76,0(61,5 - 85,0)

Conclusions: Taken together, the available evidence shows that PLWHA are protected by current WHO recommended COVID-19 vaccines.

Wastewater monitoring system for emerging infectious diseases in Thailand

Ratanaporn Tangwangvivat¹, Chadaporn Phiancharoen²

¹Department of Disease control Thailand, ²Department of Disease Control Thailand

Background and Objective: Wastewater surveillance is a beneficial method to monitor the virus especially the outbreak period but there are different benefits in each phases including pre-outbreak, during the outbreak and post-outbreak. This method is able to use for large area and it could be more efficient for the place which has the good water management system. This study aimed to identify the beneficial of wastewater monitoring system in different settings and phases.

Method: The samples were collected from different settings and phases of the COVID-19 and Monkeypox outbreak in Thailand. The selected settings were community apartments, fresh markets, prisons, and hotels. All samples were tested for COVID-19 (E gene, ORF1ab gene and N gene) and Orthopoxvirus.

Results: The results demonstrated that SARS-CoV-2 and Orthopoxvirus can be detected in untreated water. The virus could be detected the next few days after the absence of the patients. The benefits of sample collection in different outbreak phases are vary. For the pre-outbreak phase, the surveillance aimed to detect the new emerging virus as well as the infected patient to start the interventions for disease prevent and control. During the outbreak, the surveillance aimed to identify the patients and monitor the viral trend such as the mutated strain as same as the post-outbreaks phase.

Conclusion: We suggested that wastewater monitoring system is a useful method to detect the new emerging diseases and for wide-scale surveillance. Unfortunately, the different outbreak phase has an affect for sample interpretation and usage. The implementation of this method should be identified clearly before starting the protocol.

Vulnerability, COVID-19 and quality of acute neuro-cardiovascular care

Florence Francis-Oliviero¹, Florence Francis-Oliviero¹, Emilie Lesaine², Sahal Miganeh-Hadi³, Sandrine Domecq⁴, Florence Saillour-Glénisson¹, Floriane Sevin⁵

¹Bordeaux University Hospital, Bordeaux University France, ²CIC-EC, Bordeaux University Hospital, ³CIC-EC 14-01, Bordeaux University hospital France, ⁴CIC-EC 1401 - Bordeaux University Hospital France, ⁵CIC-EC 14-01, Bordeaux University hospital France The AVICOVID Group Bordeaux University France

Background and Objective: Myocardial infarction and stroke are two highly time-sensitive emergencies, which require standardized guidelines of timed care pathway to reduce treatment times. COVID-19 profoundly modified use and organization of care, as well as its access in a backdrop of pre-existing health disparities in neuro-cardiovascular diseases. Our aim was to evaluate if the first wave of COVID-19 had deteriorated quality of care for socially or clinically vulnerable stroke and myocardial infarction patients.

Methods: We included myocardial infarction and stroke patients from two French regional cohorts between January 2019 and August 2020. Associations between vulnerabilities (clinical: age over 65 years, neuro-cardiovascular history; socioeconomic: deprivation index) and care management times were analyzed through multivariate linear mixed models, with an interaction on the time period (pre, per, post-wave).

Results: 9218 patients were included (6436 strokes, 2782 myocardial infarctions). The first medical contact-to-procedure time was longer for the elderlies ($p<0.001$) and the “very disadvantaged” ($p=0.003$) myocardial infarction patients, without any interaction with the Covid-19 period (age: $p=0.541$, neuro-cardiovascular history: $p=0.697$, deprivation: $p=0.642$). In the “stroke” cohort, no significant association was found between the vulnerabilities studied and the admission-to-imaging time, with no interaction with the Covid-19 period (age: $p=0.807$, neuro-cardiovascular history: $p=0.339$, deprivation: $p=0.945$).

Conclusion: Pre-existing disparities in care management times for vulnerable

myocardial infarction and stroke patients were neither accentuated nor reduced during the first-wave Covid-19. Measures implemented during the crisis did not alter the well-structured emergency pathways for these vulnerable patients.

Gender differences in comorbidities and outcomes of COVID-19 patients: findings from the “MASSI” study

Andrea Maugeri¹, Martina Barchitta¹, Giuliana Favara¹, Roberta San Lio¹, Martina Puglisi¹, Dario Sinatra², Giuseppe Liberti², Antonella Agodi¹

¹University of Catania Italy, ²Provincial Health Authority of Catania Italy

Background and Objective: In the current COVID-19 pandemic scenario, it is necessary to understand if gender differences exist in terms of patients' characteristics and clinical outcomes. Here, we explore gender-differences in the pre-existing medical conditions, and evaluate how they might affect the risk of death among COVID-19 patients.

Methods: We used data from the MASSI (“Modelli innovativi per l'Analisi dati della Sorveglianza Sanitaria Integrata COVID-19”) study, which integrates surveillance data obtained from the Provincial Health Authority of Catania and the national surveillance system coordinated by the Italian National Institute of Health. The analysis was conducted on 1424 patients diagnosed with COVID-19 from February 2020 to December 2021 in Catania (Italy), and included patients with at least one medical condition - cancer, cardiovascular diseases (CVDs), HIV infection, chronic neurological, respiratory, corneal, kidney and liver diseases, diabetes, obesity, and other metabolic diseases.

Results: Compared to females, males were younger, more likely to exhibit diabetes ($p<0.001$), and less likely to exhibit other metabolic diseases, and obesity (p -values <0.01). However, no gender-differences were found for other medical conditions (p -value >0.05). The regression model confirmed that diabetes was more common in males (OR=1.786; 95%CI=1.362-2.343; $p=0.001$), while other metabolic diseases and obesity were less common (OR=0.607; 95%CI=0.436-0.846; $p=0.003$ and OR=0.626; 95%CI=0.451-0.868; $p=0.005$, respectively). Although no difference in mortality was evident between genders ($p=0.141$), CVDs, diabetes, kidney, chronic neurological and respiratory diseases significantly contributed to the risk of dying among males. Instead, factors that affected the probability of death among females were kidney diseases, chronic neurological and CVDs.

Conclusions: Our findings confirm gender-differences in pre-existing medical conditions of COVID-19 patients, which may influence the risk of death. Further studies, however, are needed to understand physiological and pathological mechanisms underpinning these differences.

The effect of COVID-19 pandemic on Google search activity on foods: an analysis of the public interest in Italy

Giuliana Favara¹, Andrea Maugeri¹, Martina Barchitta¹, Roberta San Lio¹, Antonella Agodi¹

¹University of Catania Italy

Background and Objective: COVID-19 pandemic had a great effect on lifestyles and behaviors, which however remains to be clarified in terms of strength and direction. Here, we analyzed Google Trends data to evaluate changes in the interest of Italian people on food categories, before and during the pandemic.

Methods: Data on internet searches from January 2018 to June 2022 were obtained from Google Trends, using the terms: fruits, vegetables, legumes, whole-grains, nuts and seeds, milk, red meat, processed meat, and sugar-sweetened beverages. For each term, relative search volume was measured and ranged from 0 (no interest) to 100 (highest interest). Joinpoint regression analysis was used to assess changes in public interest on foods, and results were expressed as weekly percent change (WPC).

Results: Public interest in fruit, vegetables, milk, and whole-grains exhibited a similar trend, with the highest peak observed during the first COVID-19 lockdown. Particularly, public interest in fruit and vegetables increased up to the highest peaks reached from 15th to 22nd March 2020 (WPC= +37.13%) and from 22nd to 29th March 2020 (WPC= +20.21%), respectively. The public interest in milk, instead, reached its peak from 23rd February to 22nd March 2020 (WPC= +36.38%). The trend was similar for whole-grains, even if the public interest reached the peak slightly after (from 12th to 19th April 2020; WPC= +4.99%). However, the interest in these foods returned to the pre-pandemic levels after the first lockdown period. Moreover, we pointed out other changes in public interest for some foods (i.e., legumes and red meat), which however were not related to the COVID-19 pandemic.

Conclusion: Our findings showed a significant influence of COVID-19 pandemic on public interest in food categories, even if this effect was limited to the first lockdown. Thus, further research should be encouraged to evaluate the long-term effect of pandemic.

Effects of bivalent Omicron-containing vaccine boosters and prior infection against SARS-CoV-2 Omicron infections in Luxembourg, September-December 2022

Dritan Bejko¹, Dritan Bejko¹, Corinna Ernst², Anne Vergison¹, Joël Mossong¹
¹Health Directorate 2A, rue Thomas Edison L-1445 Strassen Luxembourg,
²Health Directorate

Background and Objective: In Luxembourg, bivalent mRNA booster vaccines containing Omicron BA.1 or BA.4/BA.5 were introduced in September 2022 mainly targeting persons aged 60 years and older. The protection conferred by bivalent booster doses or by natural immunity due to prior infections against Omicron infections is unknown. We evaluated the effectiveness of a fourth bivalent Omicron-containing booster dose and natural immunity due to prior infection against laboratory confirmed SARS-CoV-2 infection.

Method: We conducted a test-negative matched case-control study in persons aged 60 years and older in Luxembourg during a time period when SARS-CoV-2 Omicron lineage BA.5 and its sub lineages predominated. Matching was based on age group, sex and week of test. Effectiveness was assessed using conditional logistic regression adjusting for nursing home residency, time since last dose of vaccine, geographic region, and immigration background.

Results: Data from 4714 cases and 9881 matched negative controls from September 22 through December 7 2022 were included in the analysis. The effectiveness of the fourth bivalent booster dose was 54% (95% CI 35%-67%) compared to no vaccination and 38% (95% CI 15%-55%) compared to three and 36% (95% CI 14%-52%) compared to four monovalent booster doses. Effectiveness for BA.1 and BA.4/BA.5 containing vaccines were similar ($p>0.05$). Effectiveness of prior Omicron and pre-Omicron infection were 80% (95% CI 77%-82%) and 45% (95% CI 37%-52%), respectively. Effectiveness of prior Omicron infections and bivalent booster vaccination was 87% (95% CI 72%-94%).

Conclusion: Bivalent Omicron-containing boosters were more protective against Omicron infection than monovalent boosters. Prior infection with Omicron provided a high protection, significantly better than prior infection from the pre-Omicron era. Hybrid immunity with Omicron infections and bivalent booster vaccination conferred the highest levels of protection.

Arrangement of influenza pandemic preparation and response Plan (PanFlu) in the reality of ULSS 6 Euganea

Luca Sbrogio¹, Paolo Fortuna¹, Chiara Bovo¹, Piero Realdon¹, Francesca Scotton¹, Elena Marcante², Paola Anello¹, Luca Cesaro¹, Carlo Giordani¹, Lorena Gottardello¹, Natalina Frison¹, Irene Marin¹, Tullio Zampieri¹

¹ULSS 6 Euganea Italy, ²ULSS 6 Euganea

Background and Objective: The recent Sars-Cov-2 pandemic has shown the need to provide a plan capable of responding to unpredictable events. On the basis of WHO recommendations, in January 2021 Italy adopted the National Pandemic Preparedness Plan, which was consequently implemented at regional level. Each local health authority has the task of implementing these documents by bringing it down to a local level. The ULSS6, making the most of the experience gained during COVID-19 pandemic, has organized the PanFlu Plan by identifying the main actions to be taken in preparation to a possible future pandemic.

Methods: Preparedness in public health has been assimilated to a process, so continuous improvement techniques could be used in the preparation of the plan. Ulss 6 used the Plan-Do-Check-Act (PDCA) model, organizing the work in four phases. Processes, objectives and resources were established in the Plan phase, then in the Do phase the identified managers implemented the actions. In the Check phase, feedback and results achieved were analyzed and finally the Act phase makes the document dynamic, leading to continuous improvement.

Results: The PanFlu coordination group prepared the Plan within the established deadlines. The document provides for the organizational declination of 198 actions divided into 13 macro-areas of interest involving territory, hospital facilities, prevention departments and administrative area through the various phases of a pandemic, considering aspects ranging from supplies to continuous training, from personnel recruitment to communication and logistical aspects.

Conclusion: The Panflu Plan arrangement made it possible to define the processes and the related managers for each of the actions identified, making the document

an easily applicable tool for all operators. A solid healthcare system that is aware of its internal processes and interconnections, and manages to coordinate them efficiently, will also be able to better deal with any future emergency situations.

Resurgence of the respiratory syncytial virus epidemic in infants after the easing of the COVID-19 containment measures: a retrospective cohort study from Tuscany Region, Italy

Vieri Lastrucci¹, Martina Pacifici², Giorgia Alderotti¹, Lorenzo Stacchini³, Elettra Berti⁴, Monia Puglia², Giulia Hyeraci², Giuseppe Roberto², Rosa Gini², Fabio Voller²

¹Epidemiology Unit, Meyer Children's Hospital, Florence, Italy, ²Observatory of Epidemiology, Regional Health Agency of Tuscany, Florence, Italy,

³Medical Specialization School of Hygiene and Preventive Medicine, University of Florence, Italy, ⁴Neonatal Intensive Care Unit, Meyer Children's Hospital, Florence, Italy

Background & objective: COVID-19 pandemic reduced the incidence of many viral infections in children, raising concerns about future larger epidemics with the easing of the containment measures. Respiratory syncytial virus (RSV) is a leading cause of hospitalization in infants aged <2 years, and Palivizumab is used for RSV prophylaxis. This study aimed to evaluate the impact of COVID-19 pandemic on the RSV hospitalizations and palivizumab prescriptions.

Methods: the study was funded by Tuscany Region. Five RSV epidemic seasons (2017-2022) were considered. For each RSV season, all the Tuscany Region infants aged <2 years were retrospectively followed-up in administrative databases to evaluate the occurrence of a RSV infection-based hospitalization. Trend of hospitalizations by months, seasonal incidence rates (per 1,000 person-days), and palivizumab prescriptions were the main outcomes.

Results: in total 1,756 RSV hospitalizations occurred in a population of 313,444 infants in the five seasons. In the first RSV season during pandemic (2020/2021), the RSV hospitalization incidence rate was zero. In the 2021/2022 season, the RSV epidemic started earlier and incidence rates of RSV hospitalization and severe hospitalization (23.45, 95%CI 22.84-25.25 and 5.76, 95%CI 5.46- 6.69, respectively) were about three times higher compared with pre-pandemic seasons; a significant difference in the distribution of the RSV hospitalizations for infants' gestational age at birth (GA) was observed only for GA of 32-35 weeks, while age on admission was significantly higher in 2021/2022 compared with pre-pandemic seasons. In the 2020/2021 and 2021/2022 seasons palivizumab prescriptions remained, respectively, stable (1,416) or increased (1,658), compared with the pre-pandemic average (1,343).

Conclusion: COVID-19 pandemic has caused a significant effect on the RSV epidemic. The epidemic resurgence and anticipation probably reflects the containment measures relaxation and the immune debt incurred in the previous season. Palivizumab prophylaxis was not affected by any indirect effects of the pandemic on the health service use.

Identifying risk factors for SARS-CoV-2 infection in university students after COVID-19 vaccine release: a nested case-control study

Erika Renzi¹, Valentina Baccolini², Antonio Covelli¹, Giuseppe Migliara¹, Azzurra Massimi², Corrado Vito¹, Carolina Marzuillo¹, Paolo Villari¹

¹Sapienza University of Rome Department of Public Health and Infectious Diseases, Sapienza University of Rome Italy, ²Sapienza University of Rome

Background and Objective: During the SARS-CoV-2 testing program offered through the RT-PCR test by Sapienza University of Rome, we conducted a test-negative nested case-control study between September 2021 and February 2022 to identify risk factors for acquiring SARS-CoV-2 infection among university students.

Methods: Each positive student (case) was matched with two negative students (controls), randomly selected from individuals who tested on the same day. Participants underwent a 10-minute structured interview about exposure to modifiable and non-modifiable risk factors for acquiring SARS-CoV-2 in two weeks before testing. Multivariable conditional logistic regression analyses were performed. Adjusted odds ratio (aOR) and 95% CI were calculated. A second model was restricted to participants who did not report attending campus in the two weeks before testing.

Results: Out of 8,730 tests for SARS-CoV-2, 122 of 173 cases were included in the study (response rate: 70.5%). A total of 366 students took part in the analysis. Most students were female (73.2%), with a mean age of 23.3±3.6 years, and vaccinated for SARS-CoV-2 (97.8%). At the multivariable analysis, significant

associations were found for being a case and having had a contact with COVID-19 positive person or with influenza like (ILI) symptoms (aOR: 6.51, 95%CI 3.48-12.18), attending clubs (aOR: 4.07, 95%CI:1.52-10.90), and having only the primary vaccine cycle (aOR: 2.94, 95%CI 1.24-6.96). Instead, attending lectures at the campus (aOR: 0.34 95%CI 0.15-0.77) was a negative predictor. No association was found with other predictors. The second model showed that exposure to a COVID-19 case or someone with ILI symptoms increased the likelihood of SARS-CoV-2 infection, while being female seemed to be less associated with acquiring the infection.

Conclusions: The results highlight how students who attend lectures in-person adhering to non-pharmacological preventive measures seem less exposed to SARS-CoV-2 infection. This finding suggests that the university environment appears to be safe.

COVID-19's lessons learned from Primary Care and General Practice: enduring rafts against Pandemic Waves

Lucia Palandri¹, Lucia Palandri², Alice Serafini³, Giulia Ugolini⁴, Chiara Giansante⁴, Davide Fornaciari³, Alberto Ferrari¹, Marco Saletti⁵, Marina Scarpa¹, Maria Padula⁶, Silvia Ricconi¹, Elena Righi¹

¹University of Modena and Reggio Emilia "1. Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy" Via Campi 287, Modena, Italy, ²University of Modena and Reggio Emilia Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy. Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Modena, Italy Via Campi, 287, Modena, Italy, ³Local Health Unit of Modena, Modena, Italy, ⁴Local Health Unit of Modena, Modena, Italy Department of Primary Care, Local Health Unit of Modena, Modena, Italy, ⁵Freelance Italy, ⁶University of Modena and Reggio Emilia Italy

Background: The Pandemic heavily hit northern Italy. Since most infections have mild to moderate symptoms thus Primary Care(PC) had to quickly adapt and reorganize to contribute to reducing hospital overload and ensure continuity of care. Italian literature on COVID-19 outpatient management is scarce, and little is known about overall management strategies. The study aims to describe the overall reorganization in pharmacological and monitoring strategies adopted by Italian general practitioners(GPs) to care for SARS-CoV-2 infected outpatients during the pandemic's first waves and to evaluate their effectiveness in COVID-19 hospitalisation.

Methods: This is a retrospective cohort study of SARS-CoV-2 infected adult outpatients managed by their GPs from March 2020 to April 2021 in the province of Modena(Italy). Using electronic medical records, we extracted data on pharmacological and management strategies (home visits and remote monitoring), patient characteristics, and hospitalizations. We stratified data for disease severity and multiple logistic regression analysis was performed to assess the probability of hospitalization.

Results: Of 5340 patients, 56%(83% with pneumonia) were actively monitored by 46 GPs and specifically created continuity-of-care-units. A significant reduction in paracetamol, antibiotics and hydroxychloroquine prescriptions was observed over time in concordance with newly released guidelines. FANS for moderate patients(OR=0.50 95%CI:0.25-0.99), and steroids(OR=0.52 95%CI:0.32-0.84), antibiotics(OR=0.42 95%CI:0.25-0.70) and heparin(OR=0.63 95%CI:0.38-1.04) for severe-critical patients were effective in reducing the probability of hospitalisation, yet none as much as GPs' active monitoring(OR up to 0.32 95%CI:0.14-0.70) or home visits(OR up to 0.42 95%CI:0.20-0.88).

Conclusion: Italian Primary Care showed to be resilient and prone to adapt management and pharmacological strategies effective in reducing hospitalization overload. Considering a new potential pandemic and given that the ending of the current one is still proceeding at a slow pace, strengthening and investing in territorial health systems is a key strategy for controlling hospital overload and its consequences on patients health.

²Department of Biomedical, Metabolic and Neural Sciences, Section of Public Health, University of Modena and Reggio Emilia, Modena, Italy, ³Department of Public Health, Public Hygiene Service, Local Authority of Modena, Modena, Italy, ⁴Department of Public Health, Public Hygiene Service, Local Authority of Modena, Modena, Italy, ⁵Department of Biomedical, Metabolic and Neural Sciences, Section of Public Health, University of Modena and Reggio Emilia, Modena, Italy

Background and Objective: In Italy, the COVID-19 pandemic has caused over 4.6 million cases in individuals aged between 0 and 19. This study aims to evaluate the role of vaccination against COVID-19 in order to reduce the spread of the SARS-CoV-2 virus within schools in Modena province.

Methods: A retrospective cohort study was performed in the period 1 September-15 December 2021 among teachers and students aged 0-19 years, screened for SARS-CoV-2 infection by nasopharyngeal swab following the detection of an index case within classroom.

Results: In the study period, 13934 subjects were tested, of which 12534 (90%) students and 1400 (10%) teachers, from 594 different classes. A total of 1373 cases were identified, 594 index cases and 779 secondary cases, respectively. In detail, 9.8% (1225 cases) of students tested were positive for SARS-CoV-2 and 10.6% (148 cases) of teachers. Out of entire population 32.7% (4562) of participants (64.9% of teachers and 29.2% of students) were vaccinated with at least one dose of the anti-SARS-CoV-2 vaccine at the test time. Among 779 secondary cases, only 7.7% (60) were vaccinated compared to 35.1% (4408) of negative tested subjects. Most of the subjects who tested positive attended primary school (50.8%) with the highest ratio of secondary cases on index cases rate (2.19), followed by middle (24%), high school (15.2%), infant (7.2%) and nursery school (2.7%).

Conclusion: The results of this study show the differential spread of SARS-CoV-2 within various age groups and indicate that the vaccination, available in the study period only for the population aged ≥ 12 , may have mitigated virus spread in middle and high schools. Conversely, infant and nursery schools seemed to benefit from organization in small classes.

Prevention and control of covid-19: A multicentric study of the Brazilian population in the territories covered by primary health care

Maria Guilam¹, Carla Teixeira², Julio Schweickardt¹, Diana Gutierrez Diaz de Azevedo¹, Kamile Siqueira³, Jonatas Bessa⁴, Natalia Cardoso⁵, José Pedrosa⁶

¹Fundação Oswaldo Cruz researcher Brazil, ²Fundação Oswaldo Cruz, ³Universidade Federal Fluminense, ⁴Universidade Federal da Bahia researcher Brazil, ⁵Universidade Federal do Rio de Janeiro researcher Brazil, ⁶Universidade Federal do Piaui Teacher, Brazil

Background: The COVID-19 pandemic highlighted the importance of Primary Health Care (PHC) functions in Brazil, a privileged locus for health teams to carry out educational, social, and assistance actions in the prevention and control of the disease.

Objective: This study aims to analyze the information sources and daily-life practices of the strategies for COVID-19 prevention and control in the individual, family, and collective spheres of the population in the territories covered by the PHC.

Methods: Clipping of a multicenter, national study. Cross-sectional, descriptive design, with a quantitative approach, involving 128 health units, 88 municipalities, and 5 regions of the country. Selected for convenience, with a minimum sample calculation of 6,290 families, a structured online questionnaire was used for data collection, which took place between January and September 2021. Descriptive statistics were generated for the analyses.

Results: 6,775 families were included, 41.9% stated that one or more family members had been diagnosed with COVID-19. As for self-perception about the coronavirus, 55.2% say they are very confident in preventive methods; 92.9% considered social isolation as an important preventive measure; a 95.4% reported that COVID-19 is serious and a 67.1% reported low possibility of contagion by COVID-19. As for the perception of information about COVID-19 through social networks, a 57.2% of respondents reported feeling poorly informed; a 42% reported that a health and education action was carried out to prevent COVID-19 by the team of professionals from the health unit in the territory, a 78.8% reported feeling well informed about the coronavirus by health professionals.

Conclusion: Health teams contribute to the informational universe of their users through medical-scientific guidelines. Knowing the practices of coping with the COVID-19 pandemic by the Brazilian population contributes to teams

and managers in strengthening light technologies and public policies for the prevention and control of public health emergencies.

Impact of national-scale targeted point-of-care symptomatic lateral flow testing on trends in COVID-19 infections and hospitalisations during the second epidemic wave in Austria

Stephanie Reitzinger¹, Thomas Czipionka², Werner Leber³, Jasmina Panovska-Griffiths⁴, Oliver Lammel⁵

¹Institute for Advanced Studies Austria, ²Institute for Advanced Studies Department of Health Policy, London School of Economics Austria, ³Queen Mary University of London United Kingdom, ⁴The Big Data Institute, University of Oxford United Kingdom, ⁵Practice Dr. Lammel, Ramsau am Dachstein

Background: In October 2020, amidst the second COVID-19 epidemic wave and before the second-national lockdown, Austria introduced a policy of population-wide point-of-care lateral flow antigen testing (POC-LFT). This study explores the impact of this policy by quantifying the association between trends in POC-LFT-activity with trends in PCR-positivity (as a proxy for symptomatic infection) and hospitalisations related to COVID-19 between October 22 and December 06, 2020. **Methods:** We stratified 94 Austrian districts according to POC-LFT-activity (number of POC-LFTs performed per 100,000 inhabitants over the study period), into three population cohorts: (i) high(N=24), (ii) medium(N=45) and (iii) low(N=25). Across the cohorts we a) compared trends in POC-LFT-activity with PCR-positivity and hospital admissions; and, b) compared the epidemic growth rate before and after the epidemic peak.

Results: The trend in POC-LFT activity was similar to PCR-positivity and hospitalisations trends across high, medium and low POC-LFT activity cohorts. Compared to the low POC-LFT-activity cohort, the high-activity cohort had steeper pre-peak daily increase in PCR-positivity (2.24 more cases per day, per district and per 100,000 inhabitants; 95% CI: 2.0-2.7; p<0.001) and hospitalisations (0.10; 95% CI: 0.02, 0.18; p<0.15), and 6 days earlier peak of PCR-positivity. The high-activity cohort also had steeper daily reduction in the post-peak trend in PCR-positivity (-3.6; 95% CI: -4.8, -2.3; p<0.001) and hospitalisations (-0.2; 95% CI: -0.32, -0.08; p<0.05).

Conclusions: High POC-LFT-use was associated with increased and earlier case finding during the second Austrian COVID-19 epidemic wave, and early and significant reduction in cases and hospitalisations during the second national lockdown. A national policy promoting symptomatic POC-LFT in primary care, can capture trends in PCR-positivity and hospitalisations. Symptomatic POC-LFT delivered at scale and combined with immediate self-quarantining and contact tracing can thus be a proxy for epidemic status, and hence a useful tool that can replace large-scale PCR testing.

Neutralizing anti-sars-cov-2 antibody titer after three doses of mrna vaccine in a sample of italian nursing home personnel

Annalisa Bargellini¹, Alberto Modenese¹, Stefania Paduano¹, Sara Turchi¹, Isabella Marchesi¹, Rossana Bellucci², Simona Marchetti², Roberto Vivoli², Fulvio Bruno³, Pietro Grazioli³, Fabriziomaria Gobba¹

¹Department of Biomedical, Metabolic and Neural Sciences, Section of Public Health, University of Modena and Reggio Emilia, Modena, Italy,

²Laboratorio Analisi TEST Srl, Modena, Italy, ³Fondazione Scarpini Forattini Onlus, Schivenoglia, Italy

Background and Objectives: The titre of the anti-SARS-CoV-2 antibodies 6 months after the completion of primary vaccination cycle (two doses) shows a relevant decay, as also demonstrated in our previous study in a group of Italian nursing home personnel. We decided to evaluate the trend of antibody response after a third dose of anti-COVID-19 vaccine in the same workers. The possible role of individual factors was also explored.

Methods: A mixed retrospective-prospective observational study was performed on a sample of workers (healthcare workers (HCWs) and non-HCWs from an Italian nursing home. Antibody titre was evaluated after the third BNT162b2 vaccine dose and compared with the values determined 6 months after the second dose (baseline). Moreover, individual socio-demographic and anamnestic characteristics were collected through a self-administered questionnaire.

Results: Forty-five nursing home employees vaccinated with three doses of BNT162b2 vaccine were enrolled in this follow up. Results show a significant increase of the neutralizing antibody titre after the third dose compared to the baseline (1221 BAU/ml vs 647 BAU/ml, as median values). A previous COVID-19

diagnosis and being non-HCWs were found to be associated with a higher increase of antibody titre. Analysis on individual characteristics is still ongoing, but preliminary results suggest a possible role of BMI, and age on antibody titre variation after the third vaccine dose.

Conclusion: The results show a significant increase of antibody titre in the employees of the nursing home after the third dose of BNT162b2 vaccine, supporting the importance of adherence to the proposed vaccine campaigns for the prevention of COVID-19 infection in workers.

COVID-19 testing experience among users of primary health care in communities with high socioeconomic vulnerability in northeast Brazil

Thais Aranha-Rossi¹, Sandra Barros², Ana Carvalho³, Denise Cruz⁴, Sisse Figueiredo², Camila Reis⁴, Laio Magno¹, Ines Dourado³

¹State University of Bahia - UNEB Av Silveira Martins, 2555. Cabula.

Salvador/Bahia/Brazil, ²Federal University of Bahia, ³Federal University of Bahia Av Basilio da Gama, 62. Canela. Salvador/Bahia/Brazil, ⁴Federal University of Bahia, Brazil

Background and objective: We aimed to understand the testing experience for COVID-19 (C19) among users of Primary Health Care (PHC) located in communities with high socioeconomic vulnerability in a northeastern Brazilian capital. Within the PHC model, Brazil launched the Family Health Program (FHP) in 1994, which provides a broad range of primary care services.

Methodology: This is the formative research component of an intervention study to expand the testing and monitoring of C19. A qualitative approach carried out between December/21-February/22 was used to evaluate the C19 testing experience. Seventy semi-structured interviews were conducted with PHC users. The interviews were transcribed, coded, and analyzed through thematic content analysis.

Results: Of the 70 interviews, 32 were conducted in Basic Health Units and 38 in units of the FHP. The age range was 19 to 82 years old; 62(88.6%) females and 8(11.4%) males; 47.1% of mixed race, 47.1% blacks. Only 21.4% were employed, 14.3% were retired, 27.1% did not work and 21.4% were unemployed. 31 users (44.3%) received social protection benefits (93.5% a cash transfer program or the pandemic emergency aid). Users reported barriers to accessing health services and C19 testing in PHC units during the pandemic. The reported difficulties were a limited number of tests in PHC units, long waiting time, and difficulty to access the test results. Nevertheless, almost all (69) were able to test in expanding testing options provided by the National Health System.

Conclusion: Based on the formative research results an intervention was developed for PHC in two Brazilian capitals, to respond to the barriers to accessing C19 testing. The proposed intervention seeks to expand testing; surveillance strategies, a digital platform with a real-time situation panel, availability of test results, telemonitoring and user tracking, health education material, and prevention strategies for C19.

What makes health systems resilient? an analytical framework drawing on learnings from the covid-19 pandemic

Miriam Reiss¹, Thomas Czipionka¹, Miriam Reiss¹, Markus Kraus¹, Monika Riedel¹

¹Institute for Advanced Studies (IHS), Vienna Austria

Background and Objective: The COVID-19 pandemic posed an unprecedented challenge which caught many health systems worldwide widely unprepared. The aim of this research was to develop a comprehensive analytical framework on health system resilience in the context of infectious diseases.

Methods: The analytical framework was developed based on a two-tiered approach. First, a comprehensive review of the existing literature was conducted to identify relevant frameworks on health system resilience. Second, input was gathered in several rounds of internal and external consultations with designated field experts and stakeholders, drawing on their experiences from the pandemic.

Results: The framework distinguishes between prerequisites of health system resilience, which address precautions to be taken in 'normal' times, and response strategies in the face of shocks (e.g., pandemics). Both sections are further divided into six building blocks that were adapted from the WHO health system framework: governance and leadership, information and research, financing, physical resources, human resources, service delivery. A comprehensive understanding of health systems is applied, as resilience is addressed in the action areas of public health, primary care, secondary care and long-term care. An

overarching component on contextual factors – including, e.g., social cohesion, trust, international connectedness and health literacy – represents a distinctive feature of the framework and an important addition to the existing spectrum of resilience frameworks.

Conclusion: In order to be better prepared for future health crises, the foundations for a resilient health system must already be laid in 'normal' times and in all areas of the health system. In the face of an imminent shock, adequate response strategies need to be developed. An essential learning from the COVID-19 crisis has been that contextual factors of societies and sub-groups play a major role in the ability of health systems to overcome a shock.

COVID-19 pandemic and management of migrants on quarantine vessels in Italy

Salvatore Zichichi¹, Emanuela Frisicale¹, Francesca Basile², Ignazio Schintu², Laura Pecoraro³, Claudia Marotta⁴, Domenico Stabile³, Claudio Pulvirenti³, Roberto Falvo⁴, Ulrico Angeloni⁴, Giorgia Battaglia², Giovanni Rezza⁴, Fabrizio Stracci⁴

¹University of Perugia School of Specialization in Hygiene and Prevention, University of Perugia, Perugia, Italy, ²Italian Red Cross - National Committee Italy, ³USMAF/SASN Regional Directorate of Sicily, Ministry of Health, ⁴General Directorate of Health Prevention, Ministry of Health - Italy

Background and objective: COVID-19 pandemic made the management of the thousands of migrants who have arrived on the sicilian coasts more complex and difficult. At the same time, restrictions to enter Italy were in force and reception facilities were not ready to handle several subjects in isolation and quarantine. Ships were converted into isolation structures. Syndromic surveillance and health conditions monitoring was carried out. This study describes the sample hosted in quarantine vessels and the management of covid-19 cases on board.

Methods: Vessels were converted according to the "ship safety" guidelines of the ministry of health. Ship crews, medical and logistic personnel of the Italian Red Cross were on board. Migrants were hosted according to the country of origin, gender, families, pathologies and in dedicated areas if they resulted positive to the SARS-CoV-2 when arrived at the Italian coasts. Health data of the first access were recorded in a database from April 2020 to June 2022.

Results: 59,700 migrants (6,065 women, 53,619 men, 16 not available) of 56 nationalities were hosted. The most represented countries were Tunisia (15210 migrants), Bangladesh (8959), Egypt (6918); 32 subjects declared a European nationality. The average age of the migrants who declared their age was 24.79 years old (0.38%<1y, 6.97%<18y, 8.12%=18y, 92.43%>18y). 4832 subjects (7.34%) were tested and resulted positive to the SARS-CoV-2 (58.60% before boarding and 41.4% during the quarantine period).

Conclusion: The system provided a solution quickly applicable in a context in which it was necessary to find physical places for this large number of migrants, in order to carry out isolation and quarantine with respect for human dignity. Although the system presented critical points and difficulties, it reduced the potential risk of spreading the virus among the population and in the reception system.

Inequalities in healthcare utilization among older adults during the second year of covid-19 pandemic: findings from the share cohort

Jitka Pikhartová¹, Shakirah Sharif², Hynek Pikhart¹

¹Masaryk University RECETOX Brno Czech Republic, ²UCL IEHC London United Kingdom

Background and objective: Reorganisation of healthcare resources during the COVID-19 pandemic resulted in a global disruption of healthcare services, widening health inequalities among the vulnerable, particularly the older population. This study aims to investigate the sociodemographic and geographic factors associated with healthcare disruption among older European adults in second year of pandemic.

Methods: We used Survey of Health, Ageing and Retirement in Europe (SHARE) data comprising 35,923 participants aged 50 years and above from 27 countries. The influence of sociodemographic factors from wave 7 and geographic factors (country-level COVID-19 context and welfare regime typology) on forgone, postponed and denied healthcare in 2021 (wave 9), controlling for health needs, health behaviours, and COVID-19 vaccination status was investigated using three multilevel logistic regression models.

Results: Among older Europeans, the reported prevalence of forgone, postponed, and denied healthcare were 8.8%, 12.1% and 5.7%, respectively. Those higher

educated had higher likelihood of healthcare disruption. Compared to primary-educated, those tertiary-educated had 44% (95%CI 28-62%), 24% (13-37%) and 50% (28-75%) higher odds of forgone, postponed and denied healthcare, respectively. Those with secondary compared to primary education had 15% (4-27%) higher odds of forgone healthcare. Retirees faced higher chance of postponed healthcare compared to employed (OR 1.26, 1.00-1.62). Those living with partners were less likely (0.91, 0.83-0.99) to experience forgone healthcare. Country-level COVID-19 case and death numbers, stringency of measures against COVID-19 and welfare regime typology were not associated with healthcare disruption. The models for each outcome variable explained 8-9% differences between countries.

Conclusion: Differences in healthcare utilisation among older Europeans based on sociodemographic factors persisted in the second year of COVID-19 pandemic. Strategies to mitigate the repercussion of missed and unmet healthcare should be put in place to ensure preservation of health and wellbeing of this vulnerable population.

Use of the anti-covid vaccination status to support bed management activity as a preventive measure in the development of epidemic outbreaks

Michele Lagioia¹, Veronica Ciorba², Michele Capraro¹

¹IRCCS Istituto Clinico Humanitas Italy, ²IRCCS Istituto Clinico Humanitas

Background and objective: The large-scale introduction of anti-COVID vaccination has been shown to reduce the probability of contracting and spreading the infection by the vaccinated person. The diagnostic capacity of the nasopharyngeal swab for COVID+ is limited at the time of its execution, failing to identify subjects who are in the incubation period and therefore with limited efficacy in preventive identification at the time of hospitalization. To limit the development of intra-hospital clusters of COVID+, a bed management model was structured based on the vaccination status recorded in the electronic medical record and on the length of hospitalization.

Methods: Starting from April 2021, the vaccination status for all hospitalizations, recorded on electronic health records, was extracted in daily reports provided to bed management. The bed management model used provided for the prohibition of sharing the hospital room between unvaccinated subjects or the possible association of long-term patients.

Results: The incidence of clusters (more than two cases in 7 days per unit of stay) in the hospital in the quarter following the implementation of this model showed a percentage reduction of 72.5%.

Conclusion: optimal management of patient placement in small cohorts according to public health criteria can help reduce the occurrence of infectious complications

Primary care during the pandemic: lessons learnt from five European countries

Markus Kraus¹, Christoph Stegner², Miriam Reiss², Thomas Czipionka², Monika Riedel²

¹Institute for Advanced Studies (IHS), Vienna Josefstaedter Straße 39 1080 Vienna Austria, ²Institute for Advanced Studies (IHS), Vienna Austria

Background and objective: The COVID-19 pandemic necessitated wide-ranging adaptations to the organisation of health systems, and primary care is no exception. This study aims to collate insights on the various impacts of the pandemic on primary care. The gained knowledge should help to increase pandemic preparedness and resilience of the primary care system.

Methods: We conducted a qualitative study employing semi-structured interviews with primary care providers in Austria, Denmark, France, Hungary, and Italy. A total of 31 interviews were conducted between June and August 2022 and subjected to an overarching analysis to identify key themes.

Results: Disruptions to service delivery led to a widespread adoption of telemedicine. Despite the rapid increase in telemedicine usage and efforts of primary care providers to organise face-to-face care delivery in a safe way, some patient populations such as elderly or chronically ill patients were particularly affected by disruptions in service delivery. Moreover, primary care providers perceived a substantial propagation of misinformation about COVID-19 and vaccines among the population, which also threatened patient-physician relationships. At the same time, primary care providers faced an increased workload, had to work with insufficient personal protective equipment and were provided with incongruous guidelines while pandemic response policies were mostly focused on hospitals. There was a consensus among primary care providers that they were mostly sidelined by public health policy in the context of pandemic management.

Conclusion: A better integration of primary care with public health and a better involvement of the primary care sector into the pandemic response would have generated a benefit for both patients and care providers. Primary care is well-equipped to manage most mild cases, thereby potentially relieving pressure from hospitals. Continuity of usual care should be prioritised and can be safeguarded by care provision via telemedicine or face-to-face, depending on the individual case.

Household food security access and dietary diversity amidst covid-19 pandemic in nepal; an evidence from rapid assessment Dirghayu K.C.¹

¹Public Health Promotion and Development Organization Dhapakhel Nepal

Background: Pandemic led to the surging concerns of food insecurity status throughout the world. In response to global and national concerns on food and nutrition security, the presented study aimed to examine the prevalence and determining factors of household food insecurity and dietary diversity among people from selected rural municipalities of Lalitpur, Nepal.

Methods: A community-based cross-sectional study was conducted among 432 households. A pretested, semi-structured questionnaire was used to collect socio-demographic characteristics of the participants, household income; the impact of COVID-19 on their income and livelihood, household access to food, and dietary diversity. Food insecurity was measured using the Household Food Insecurity Access Scale (HFIAS), version 3, and the Household Dietary Diversity Score (HDDS). Bivariate and multiple linear regression models were used to assess the association between the dependent and independent variables.

Results: This study found the prevalence of household food insecurity, and low/medium household dietary diversity were 36.1% (95% CI: 31.7-40.8), and 63.2% (95%CI: 58.5-67.6) respectively. Also, households receiving COVID-19 support have had a significantly positive association with the HFS score (COR=1.62, 95% CI: 1.03-2.53) compared to those who did not receive any form of support. Multiple regression showed the disadvantaged ethnic group (AOR=2.73, 95% CI: 1.23-6.07), who did not attend formal education had significantly higher odds of household food insecurity (AOR= 3.70, 95% CI: 1.16-11.71). In contrast, participants of the age group 41-64 years were less likely to have food security and have consumed diverse diet (AOR=0.35, 95% CI: 0.21-0.59), and (AOR=0.48, 95% CI: 0.28-0.83), respectively compared to the reference group of 20-40 years.

Conclusion: Owing to the pandemic, our study concluded the increased prevalence of food insecurity among diverse communities. Despite this, dietary diversity was found to be acceptable, indicating the much-needed attention on food security in forthcoming emergencies among those of such rural settings.

Association between bnt162b2 vaccination and quality of life up to 18 months post-covid19 among sars-cov-2 infected individuals in israel: a cross sectional survey

Paul Otiku¹, Hiba Zayyad², Ofir Wertheim², Kamal Jabal², Amiel Dror³, Saleh Nazzal⁴, Daniel Glikman², Michael Edelstein¹

¹Azrieli Faculty of Medicine, Bar-Ilan University Israel, ²Baruch Padeh Hospital Israel, ³Ziv Medical Centre Israel, ⁴Galilee Medical Centre Israel

Background and objectives: Approximately 10-30% proportion of SARS-CoV-2 infected individuals continue to report symptoms months after the acute infection. Despite a growing consensus that vaccination reduces the reporting of these long-term symptoms, whether vaccination mitigates changes in quality of life (QoL) associated with post-acute COVID19 symptoms has not been fully investigated. We aimed to identify any association between the BnT162b2 vaccination use in Israel and QoL among individuals previously infected with SARS-CoV-2 in Israel, 3 to 18 months after infection.

Methods: We invited individuals aged 18 years and older whose SARS-CoV-2 r polymerase chain reaction (PCR) test was analysed between 15th March 2020 and 15th June 2022 in one of three government hospitals in Northern Israel, to fill a questionnaire pertaining to their physical, mental and psychosocial health. We examined associations between their vaccination status and post-COVID HRQoL (measured using the EQ5D-5L Utility index (UI) that ranges from less than 0 (lowest QoL) to 1) using linear regression, after adjusting for potential confounders.

Results: 951 participants with complete data were included. Mean UI for participants unvaccinated at the time of infection was 0.77, compared to 0.82 and 0.83 for double and triple vaccinated participants respectively. After adjusting for potential confounders, double and triple vaccination was associated with a 6.1

and 5.6 percentage-point increase in QoL respectively 3-18 months post-SARS-CoV-2 infection, compared to those unvaccinated ($p < 0.05$).

Conclusions: Vaccination with 2 doses or more of BNT162b2 vaccine was associated with better QoL outcomes 3-18 months post infection compared to those unvaccinated at the time of infection. Our results suggests COVID-19 vaccination not only reduces post-acute COVID19 symptoms but may also mitigate the decrease in quality of life associated with symptoms post-acute COVID19 illness.

Malaka Raya, RT.12/RW.6, Malaka Sari, Durenawit, East Jakarta City, Jakarta 13460 Indonesia

Background: Indonesia is a disaster-prone country, so it needs preparedness to deal with it. One of the components that is the focus of a disaster is health services, including in non-natural disasters such as the COVID-19 pandemic. Primary health services were not ready when the pandemic hit in March 2020. Depok City is the city with the first case of COVID 19 in Indonesia.

Objective: Identify the resilience of primary health services (Community Health Centers) in the COVID 19 pandemic situation

Methods: We use a cross-sectional method to measure the level of resilience base on 5 variables namely governance, financial, resources and health workforce, technology and medical product uses, and services delivery. The population of this study were health workers working at the Depok City Community Health Centers in 2022 with a total sample of 111 people from 30 health centers. Respondents filled out the questionnaire using the Google form which was directly supervised by researchers in November 2022.

Results: The results show that in general resilience level of health system in Depok City based on measurement at community health center level is in a good situation (average 61,66%). Variable of resources and health workforce is the highest score (79,3 %) followed by technology and medical product uses (76,6 %), governance (56,8 %), services delivery (52,3 %), and financial (42,3 %).

Conclusions: We conclude that health system resilience in Depok City – Indonesia based on measurement at community health center level is in a good situation. Some component of health system needs to be enhanced in order to improve general resilience as preparedness step to face upcoming possible health crisis

IRCCS Women, Children and Public Health Sciences Department, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background and objective: Pregnant women (PW) have a high risk of complications and adverse fetal/neonatal outcomes from COVID-19; therefore, they are a priority target group for COVID-19 vaccination. Despite the large real-world evidence about its safety in pregnancy, hesitancy is widespread and vaccination acceptance is low among PW. Following the World Health Organization's guidelines, COVID-19 vaccination of PW has been recommended in Italy since September 22nd, 2021. Shortly after, the Fondazione Policlinico Universitario Agostino Gemelli IRCCS (FPG), in Rome, implemented and promoted a specific pathway for COVID-19 vaccination of PW at its vaccination center. A cross-sectional study was conducted to assess the degree of pre-vaccinal doubt about COVID-19 vaccines, and the information sources considered decisive for the vaccination choice among PW vaccinated against COVID-19 at the FPG between October 2021 and March 2022. **Methods:** Data were collected through an anonymous questionnaire, composed of linear scale questions investigating doubts, and a multiple-answer question regarding sources. A score was calculated to assess the degree of doubt (low, medium, high). Multivariate logistic regression was performed to identify factors associated with the variables of interest, setting statistical significance at p

Leveraging Electronic Immunization Registry to monitor the two-year impact of COVID-19 on uptake of routine immunizations in children under 2 years of age in Sindh, Pakistan: insights from big data analysis with > 6.9 million children

Muhammad Siddique¹, Sundus Iftikhar¹, Mubarak Shah², Vijay Dharma¹, Danya Siddiqi³, Subhash Chandir⁴, Mariam Mehmood⁵

¹IRD Pakistan Pakistan, ²IRD Global Canada, ³IRD Global United Kingdom,

⁴IRD Global United States, ⁵IRD Pakistan

Background and objective: The covid-19 pandemic has disrupted routine immunizations globally, with low-middle-income countries (lmics) struggling to achieve pre-covid-19 coverage rates. We leveraged real-time immunization records of >6.9m children from the government's electronic immunization registry (seir) in sindh, pakistan, to quantify the pandemics 2-year impact on routine childhood immunizations, including the success and inclusiveness of catch-up strategies.

Methods: We extracted individual immunization records from the seir from march 23, 2019 to march 22, 2022. Comparing baseline (1-year preceding the first lockdown) and the 2-year covid-19 period, we analyzed the impact on daily immunization coverage rates and impact heterogeneity in coverage across gender and geographies. furthermore, we examined the success and inclusiveness of post-covid-19 catch-up strategies for missed children.

Results: We found a 48% (21,440/45,024) and 89% (40,033/45,024) decline in the daily average number of vaccine doses administered during the first and second covid-19 lockdowns compared to the baseline. Immunizations declined more for girls vs. Boys and in slums and rural areas compared to non-slums and urban areas. Of the 3.8m children who missed immunizations during the 2-year covid-19 period, 76% (2,919,683/3,818,716) were covered at the two-year mark. Despite covid-19 disruptions, the daily average number of vaccine doses administered at the one- and two-year mark surpassed the baseline rates in sindh by 22% (10,063/45,024) and 21% (9,365/45,024). Moreover, the female-based gender equity improved at the 2-year mark (crude male-to-female ratio (m:f) =1:1.09) compared to baseline (crude m:f=1:1.10)

Conclusion: Seir was crucial in supporting epi activities to trace, target and immunize children who missed immunizations during the 2-year covid-19 period. Pakistan is among the countries that successfully leveraged eirs during the pandemic to monitor immunization trends and transform data into actionable insights for evidence-based decision-making.

Effectiveness of vaccination on hospitalisation related outcomes: a population-based study in Northern Italy

Antonio Lorenzon¹, Lucia Palandri², Catalina Cristofor³, Filippo Lozza³, Francesco Uguzzoni², Cristiana Rizzi, Riccardo Poluzzi¹, Maria Scasserra³, Pierpaolo Bertoli¹, Florian Zerzer⁴, Elena Righi⁵

¹University of Modena and Reggio Emilia Department of Biomedical, Metabolic and Neural Sciences Via Campi 287, 41125 Modena, Italy,

²University of Modena and Reggio Emilia, ³South Tyrol Health Care Service Epidemiological Surveillance Unit Via Lorenz Böhler 5, 39100, Bolzano, Italy,

⁴South Tyrol Health Care Service Medical Management Via Lorenz Böhler 5,

39100, Bolzano, Italy, ⁵South Tyrol Health Care Service General Management Via Thomas Alva Edison 10/D, 39100, Bolzano, Italy

Background and objective: Although the efficacy of SARS-CoV-2 vaccines in preventing severe disease – especially in older adults – is widely demonstrated, there are not many studies conducted in the Alps with large sample sizes and during Omicron variant period. Moreover, scarce literature analyses the hospitalisation length of SARS-CoV-2 patients and its association with vaccination status. Aim of this study is to investigate the associations between ordinary or intensive care unit (ICU) hospitalisations and the vaccination status of SARS-CoV2 adult patients resident in the Italian alpine province of Bolzano.

Methods: We collected anonymized data from 93643 patients who swabbed positive for SARS-CoV-2 between November'21 and February'22 – coinciding with the arrival of the Omicron variant. Associations between vaccination status and hospitalisation characteristics were assessed using bivariate statistics and multiple logistic regression.

Results: Of 93643 positive patients, 925 were hospitalised (90% ordinary ward, 10% ICU).

Among over 65 (8% of the sample and 68% of hospitalisations), vaccinated patients had a significantly lower risk of being admitted to ordinary wards compared to not vaccinated: Odds Ratio(OR)=0.40(CI:0.35-0.48); to ICU: OR=0.26(CI:0.15-0.47) and to die: OR=0.39(CI:0.29-0.52).

These risks were even lower for vaccinated with booster compared to unvaccinated. Suggestively, also among vaccinated patients those with booster showed decreased risk of hospitalisation: OR=0.54(CI:0.42-0.67); and death: OR=0.39(CI:0.25-0.61).

Similar associations were found in age range 30-65.

Finally, average duration of ICU stay was significantly longer for unvaccinated people compared to vaccinated (9-6 days; p<0.003), especially in over 65 (11-6 days; p<0.05).

Conclusion: Results suggest that vaccination played a protective role against severe disease, even during Omicron variant period and especially in the most at-risk age groups.

Additional/booster dose have granted a greater protection compared to the primary cycle, supporting its administration policy.

The shorter ICU stay of vaccinated people suggests that vaccination could have made recovery faster.

Living rapid review update 18: what is the specific role of schools and daycares in covid-19 transmission?

Selin Akaraci¹, Sarah Neil-Sztramko², Leah Hagerman³, Emily Clark³, Emily Belita⁴, Stephanie Hopkins³, Robyn Traynor³, Karlene Stoby³, Maureen Dobbins³

¹Centre for Public Health, Queen's University Belfast United Kingdom,

²National Collaborating Centre for Methods and Tools, McMaster University,

³National Collaborating Centre for Methods and Tools, McMaster University Canada, ⁴McMaster University

Countries have implemented various policies to tackle the COVID-19 pandemic. As pandemic conditions evolved and the body of evidence grew, the question of how to safely operate schools and daycares remained unanswered. To support evidence-informed decision-making, the National Collaborating Centre for Methods and Tools maintained a living rapid review to synthesize evidence on the role of schools and daycares on COVID-19 transmission. The search included 31 databases and grey literature sources, including Medline, Embase, PsycINFO, ERIC and medRxiv. Included studies reported data from 2021 forward on transmission (number of cases, cases/population or secondary attack rates (SAR)) within schools/daycares, the impact of infection prevention and control (IPAC) measures on transmission within schools/daycares, or the impact of operating schools/daycares on community transmission. All studies were critically appraised, and the certainty of evidence was evaluated using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach. In the most recent update (December 2022), 58 single studies and 7 syntheses were identified. Results illustrate that SARs are low within school settings when IPAC measures are in place (certainty: moderate). Regarding IPAC measures, face masks may reduce the risk of transmission (certainty: low), test-to-stay policies may not increase transmission risk vs mandatory quarantine (certainty: low), cohorting and hybrid learning may make little to no difference in transmission (certainty: low), and the impact of surveillance testing within schools remained inconclusive (certainty: low). Incidence rates among students and staff were similar to community trends, indicating that school settings do not meaningfully contribute to community incidence, hospitalizations or mortality (certainty: low). The 18th

update to this living review includes higher-quality surveillance data and whole-genome sequencing studies, which build upon early case reports and prevalence studies to increase the certainty of findings. Living reviews may help to support ongoing decision-making in the context of evolving pandemic conditions.

Prerequisites and response strategies for tackling a pandemic: lessons for secondary care from five European countries

Monika Riedel¹, Miriam Reiss¹, Markus Kraus¹, Thomas Czipionka¹

¹IHS Austria

Background and objective: The COVID-19 pandemic clearly highlighted the limited capacities in health systems including hospitals. This study collates experience and insights on challenges and strategies in secondary care management during the pandemic. The gained knowledge should help to facilitate pandemic preparedness in hospital care.

Methods: 52 semi-structured interviews with managers and executive staff of hospitals in Denmark, France, Germany, Hungary and Italy were conducted in Summer 2022 and were analysed by researchers in the respective countries. Subsequently, an overarching analysis was conducted to identify key themes and derive recommendations for improved preparedness.

Results: Despite marked differences between their national health systems, the investigated countries encountered similar problems. Concerning prerequisites, experts from most countries noted lack of up-to-date or sufficiently tested pandemic plans, too scarce resources dedicated to information transfer, including insufficient availability or usability of IT systems within and across organisations. Pandemic responses worked best in case of pre-existing cooperations and due to highly motivated staff. Often, in-house solutions for emerging problems were developed before support from authorities arrived. Keeping staff motivated and healthy got increasingly difficult due to the duration of the crisis, burden of work, diminishing societal support, poor governance regarding administrative burdens and (monetary) recognition of work.

Conclusion: The pandemic intensified pre-existing problems in the hospital sector – most notably, staff shortages and information management deficits – and accelerated developments that had begun already pre-pandemic. Experts from all five countries agreed that better equipped and integrated primary care and more suitable e-health solutions could take strain off hospitals. Professional managerial support for health organizations could improve processes. Regular practical tests of pandemic plans would point out needs for updates as well as trainings and other resources, thus enabling providers to concentrate on their core tasks in times of crisis.

COVID-19 infection in healthcare workers in ancona, Italy, 2020-2022: an observational longitudinal study

Davide Detto Rinaldini¹, Corinna Fortunato¹, Giulia Paolorossi¹, Jacopo Dolcini¹, Pamela Barbadoro¹

¹Department of Biomedical Sciences and Public Health, Università Politecnica delle Marche, Ancona, Italy

Background and Objective: As of January 2020, a new type of Coronavirus started to spread globally. Healthcare workers (HCWs) are exposed to a high risk of infection. Our study aims to describe the trend of SARS-CoV-2 infections within HCWs of the Azienda Ospedaliero Universitaria (AOU) delle Marche.

Methods: We carried out an observational longitudinal study; data has been collected from the records of the Hospital Hygiene Department of the AOU delle Marche. Among all the employees with a permanent contract (3280), only those with a positive SARS-CoV-2 swab result in the period from the 17/03/2020 to 24/03/2022 have been included.

Results: During study time, 794 operators tested positive corresponding to 23.6% of all employees (95%CI 22.0-25.3).

The sample was constituted of 597 (75.19%) females and 197 (24.81%) males. There was a higher incidence among employees under 30 years of age, followed by those aged 30-39.

Comparing the Sars-CoV-2 incidence in the Italian population with the HCWs' one, the incidence in March 2020 was lower in the first group.

From May 2020 to September 2020, the incidence in both populations was comparable. From December 2020, the incidence among healthcare employees decreased more drastically than in the general population and remained lower even in the following months (February - May 2021). The arrival of the Delta variant in May 2021 did not seem to affect the number of positive cases but, from November 2021 with the Omicron variant, there was a sudden increase in

incidence in both groups.

Conclusions: Although healthcare workers were more exposed to the virus and were more frequently screened, their risk of infection was not higher than the general Italian population.

This was probably because of the anti-SARS-CoV2 vaccination that has been administered primarily to HCWs starting from 27/12/2020 and to stricter adherence to personal protective equipment use.

Health needs of migrants hosted on quarantine vessels in Italy during COVID-19 pandemic

Emanuela Frisicale¹, Salvatore Zichichi², Francesca Basile³, Ignazio Schintu², Giorgia Battaglia², Claudia Marotta¹, Ulrico Angeloni¹, Roberto Falvo¹, Laura Pecoraro⁴, Domenico Stabile⁴, Claudio Pulvirenti⁴, Fabrizio Stracci², Giovanni Rezza¹

¹Directorate General of Health Prevention, Ministry of Health, Rome, Italy,

²School of Specialization in Hygiene and Prevention, University of Perugia, Perugia, Italy - Italian Red Cross, ³Italian Red Cross - National Committee, Rome, Italy, ⁴Cross border Health Authorities (USMAF-SASN), Ministry of Health, Palermo, Italy

Background and Objective: The southern coasts of Italy have been characterised by massive influxes of migrants from the coasts of North Africa for several decades.

COVID-19 pandemic has increased the complexity of the management of migrants flows because of the cross-border rules and the need to contain potential SARS-CoV-2 outbreaks and not to burden local health services. To carry out quarantine at point of entries or isolation for SARS-CoV-2 infection if asymptomatic or paucisymptomatic, before reaching reception facilities, migrants were hosted in Ro-Ro vessels where also healthcare interventions were delivered by Italian Red Cross personnel with the collaboration of the Ministry of Health. This study aims at exploring which healthcare interventions were delivered on board from 17/04/2020 to 6/06/2022 in order to investigate migrants' health needs.

Methods: All data were collected on board and registered in an informative system. A descriptive analysis of the sample and of healthcare interventions was carried out through Excel functions.

Results: 20 "Ship Missions" were conducted during the reference period. 59.684 migrants (10% female, 7% minors) were welcomed and managed in 13 quarantine vessels. 23.775 healthcare interventions were delivered, among these 27% were psychological counselling, 16% dermatological consults, 12% dressings, 9% gastrointestinal consultations, 5% otolaryngology visits, 4% orthopedics consults. The remaining ones were medical or nursing interventions (for example psychiatric or ophthalmic). Overall, only 134 (0.6%) medical transfer to hospitals or healthcare services on the ground were carried out.

Conclusion: Most of migrants asked for psychological support probably due to their past. Most of the other interventions delivered seem to be at the same time indicative of health needs emerged during migration route. Moreover, the presence of healthcare personnel on board, leading to promptly manage migrants' health and healthcare needs, avoided medical transfers and the overburdening of local health services.

Epidemiological transmission patterns and use of whole genome sequencing in investigating campus based covid-19 outbreaks during the second and third waves of SARS-Cov-2 infection

Jwenish Kumawat¹, Devisri Sundaram², Mary Codd¹, Eamonn Gormley¹, Anne Scrivener², Peter Coulahan¹, Patrick Wall¹

¹University College Dublin School of Public Health, Physiotherapy and Sports science "University College Dublin, Woodview House, Belfield, D04 V1W8, Dublin" Ireland, ²University College Dublin

Background: This study describes the investigation and management of multiple outbreaks of SARS-Cov2 during the second and third wave of the pandemic at University College Dublin, Ireland from September 2020 to September 2021.

Methods: Relevant data were gathered as part of the public health outbreak investigations led by the UCD Internal COVID Control Team (ICCT) in collaboration with the public health teams of the Health Service Executive (HSE). Results are presented for PCR (polymerase chain reaction) confirmed cases and their close contacts, reported to the UCD ICCT between September 2020 to September 2021. **Results:** There were 189 cases notified to ICCT. Among these, 77 cases were in residence on-campus cases. Ten epidemiologically linked clusters identified, where the number of cases linked with each cluster varied between 2 to 12. Additional cases during this period had no obvious epidemiological link to the

identified clusters. Of 843 close contacts with PCR test results, 26% (n=217) tested positive. 77% (n=145) self-reported with mild to moderately symptoms while 23% (n=44) self-reported as asymptomatic. Retrospective Whole Genome Sequence (WGS) analysis was undertaken after the outbreaks had subsided. The test positive cases were grouped into 6 clusters and it was shown that many of the apparent sporadic cases were included in these clusters.

Conclusions: The proportion of close contacts testing positive varied significantly throughout the pandemic, with testing policy and type of exposure having the greatest impact. Whole genome sequencing can give a better understanding of webs of transmission to complement epidemiological investigations. It is now possible to undertake sequencing in real time where it can make a contribution to outbreak control and resolution. Public Health professionals should become familiar with WGS and bioinformatics as useful tools in their armoury for the control of all communicable diseases not only SARS-CoV-2.

Policies and practices to attract, retain, support and reskill health and care workers during the covid-19 pandemic and future workforce development in Thailand

Vichai Tienthavorn¹, Wanicha Chuenkongkaew¹, Vasuton Tanvatanakul¹, Sukjai Charoensuk², Phayong Thepakorn²

¹Praboromarajchanok Institute, Ministry of Public Health Thailand,

²Sirindhorn College of Public Health, Trang, Faculty of Public Health and Allied Health Sciences, Praboromarajchanok Institute

The low number of COVID-19-positive cases in Thailand indicates the robustness of Thailand's Ministry of Public Health(MoPH) and health-care system in responding to public health responses and emergencies. Its comprehensive duty is to lead the emergency response to prevent, contain, and control health challenges ranging from the national agenda to primary care in the communities. Key elements for tackling burdens include building the health workforce capacity and crafting public health policy that facilitate the capacity to respond to this pandemic.

To enhance the capacity of health-care workers to respond to the pandemic, Praboromarajchanok Institute (PI) is a higher educational institution whose main mission is to produce and develop human resources according to the needs of the MoPH. PI has both implemented new policies and strengthened current policies to attract, retain, support and re-and up-skill health care workers during COVID-19 in Thailand. PI promotes community health through its affiliated colleges, which are located in every region of the country. PI also has close relationships with the communities it serves, which are akin to family. PI has been fully integrated at the primary health-care level, through its community and health promoting hospitals that provide first-contact services available to everyone.

To make health systems more resilient to disaster preparedness and crises, PI plays a major role in producing health science graduates. These graduates serve as health personnel in rural areas, and make up more than half of the health workforce in the country. The MoPH and PI has greatly contributed to solving the national crisis on COVID-19. It promoted proactive action to prevent and monitor the spread of COVID-19 through village health volunteers (VHVs). VHVs use a smartphone application tool for surveillance of the COVID-19 epidemic. PI also now offers additional instruction for VHVs in nursing assistant and public health assistant program.

Epidemiological profile of covid-19 deaths in tunisia, 2020-2022

Rim Mhedhebi¹, Sonia Dhaouadi², Nissaf Alaya², Aycha Hechaichi², Amenallah Zouayti², Hejer Letaief², Mouna Safer², Chiraz Borji³, Emna Mziou², Fatma Youssef², Leila Bouabid², Souha Bougatef², Sondes Derouiche²

¹National Observatory of New and Emerging Diseases Ministry of Health, Tunisia Tunisia 16 Rue Bayrem Tounssi Tunisia, ²National Observatory of New and Emerging Diseases Ministry of Health, Tunisia, ³Ministry of Health, Tunisia Tunisia

Background

The impact of SARS-CoV-2 on global public health and excess of mortality related to coronavirus disease-2019 were proven worldwide.

This study aimed to describe the epidemiological profile of COVID-19 deaths in Tunisia from march 2020 to November 2022, to inform prevention and control policies.

Methods: Tunisian COVID-19 deaths register were implemented since March 2020 by National Observatory of New and Emerging Diseases, Tunisia from three data sources (Regional Directorate of health, public and private health care centers...). Qualitative variables were described by number and percentages. Crude mortality

rate (CMR) per 100,000 inhabitants was calculated as the rate between the number of COVID-19 deaths and the size of population.

Results: Between 18 March 2020 and 13 November 2022, Tunisia has reported 29266 covid-19 deaths (CMR=247.9 per 100,000 inhabitants).

The southern region has been the most affected throughout the COVID-19 epidemic (2020-2022) with the highest CMR. The epidemiology of COVID-19 in Tunisia was found to be spatiotemporally diverse. The epidemiological death indicators varied by region and time with periodic large outbreaks. The severity varied over time with 5 outbreaks occurring between September 2020 and November 2022 with the circulation of new variants of concern.

The median age of deaths were 72 years (0 days (newborn) to 112 years). The sex-ratio M/F=1.4, the number of COVID-19 death was higher among male and adult population. About 7% occurred at home or in way to a health care center and 93% occurred in health care centers (10% of these deaths occurred in private centers). Conclusion: The combination of public health, non-pharmaceutical measures and the high vaccine coverage were the most important pillars to contain this pandemic and mitigate its severity The implementation of the national immunization program must continue to contain the pandemic.

The use of telemedicine by physicians during the covid-19 pandemic in Brazil

Ana de Sousa van Stralen¹, Cristiana Carvalho², Samuel Gomes da Silva¹, Jackson Araujo¹, Lucas Der Maas¹, Joana Cella¹, Ana Maciel Chagas¹, Valeria Penzin Goulart³, Leda de Oliveira³, Sabado Girardi⁴

¹Federal University of Minas Gerais Brazil, ²Pontifical Catholic University of Minas Gerais, ³Oswaldo Cruz Foundation Brazil, ⁴leda.oliveira@fiocruz.br Brazil

Background and objectives: The COVID-19 pandemic had a stimulating effect on the use of telemedicine worldwide. The present study aimed to investigate the use of telemedicine by physicians in Brazil prior to and during the pandemic.

Methods: We carried out a descriptive exploratory cross-sectional study through an online survey with 2.541 physicians in Brazil between October 2020 and January 2021. Respondents were classified according to their primary specialties. Results: The prior use of telemedicine was more common among primary care physicians: 22% of respondents in this group already used telemedicine and 13,7% started to use it after the pandemic. However, most of the respondents started using telemedicine after the break of the COVID-19 pandemic: 41% of clinical specialists, 35% of primary care physicians, and 27,6% of surgical specialists. Among diagnostic/therapeutic specialists, 44% declared that they did not use or intend to use telemedicine in the future. More than half of the respondents declared not to have received any additional payments related to telemedicine, especially among primary healthcare physicians (80%). 66% and more of the respondents from all specialty groups believe that the use of telemedicine expands access to health care services. However, with the exception of primary care physicians, the majority opinion of the respondents is that telemedicine can reduce the quality and safety of care.

Conclusion: The use of telemedicine prior to the pandemic was more common among primary care physicians. Despite having expanded the use of this tool in all groups of specialists, in comparison to the others, primary care physicians still demonstrate greater familiarity with the use of telemedicine and possible benefits for health services.

Popul. Med. 2023;5(Supplement):A449
DOI: 10.18332/popmed/164691

A multi-country assessment of societal resilience and preparedness during covid-19 times. A review among the coronadex horizon 2020 project

Anna D'Amelio¹, Cristina Renzi², Sarah Cataldi², Giulia Dallagiocoma³, Gianmarco Imperiali², Anna Odone³, Carlo Signorelli¹

¹San Raffaele University - UniSR "Via Olgettina, 60 Milan" Italy, ²San Raffaele University - UniSR Italy, ³University of Pavia Italy

Background and Objective: The COVID-19 pandemic has led to complex challenges concerning the spreading of misinformation about origin, symptoms, and prevention of SARS-CoV-2. Unclear, changing, and variable guidelines confuse the public and plant seeds for misinformation. A wide range of strategies were used by leaders across many sectors to foster positive social norms and encourage people to protect their community and selves from COVID-19.

The study provides an overview of communications important role in influencing society's behaviour during the COVID-19 pandemic in ten different countries.

Methods: This paper presents a narrative analysis of the currently available data

on societal responses and resilience during the COVID-19 pandemic, spanning from February 1, 2020, to March 1, 2022. Ten nations – Italy, Denmark, Sweden, Israel, Spain, Portugal, Romania, France and Germany, United Kingdom, and Israel – were selected for inclusion both within and outside the EU, based on their heterogeneous COVID-19 responses. Academic literature was retrieved using PubMed/Medline and Google Scholar. Grey literature was consulted ranging from institutional reports to archival records, policy briefs, books, websites, and news from verified sources.

Results: Adoption of domestic and travel regulations was different across countries, some more efficient than others. Some specific official communication strategies about COVID-19 have shown to be effective in increasing vaccine uptake while social media as source of information was strongly related to vaccine hesitancy. Israel and Portugal were exploited as benchmarks for vaccination strategies by other countries.

Conclusions: Low public confidence due to infodemic and inconsistent policies underscored the central role of Public Health to develop proper strategies and exploit digital tools to increase awareness. The potential of social media and digital platforms in tackling health emergencies should be better understood. Additionally, healthcare workers' communication skills can be improved to effectively deal with future epidemics and be trusted by the population.

Gender differences in covid-19 vaccine hesitancy in Western Balkans

Stefan Mandić-Rajčević¹, Janko Janković², Smiljana Cvjetković³, Vida Jeremić-Stojković⁴, Sanja Matović-Miljanović⁵, Aleksandar Stevanović⁶, Michele Gross⁵

¹University of Belgrade, Faculty of Medicine, Belgrade, Serbia Institute of Social Medicine and School of Public Health and Health Management Dr Subotića 15 Serbia, ²Institute of Social Medicine and School of Public Health and Health Management, Serbia, ³University of Belgrade, Faculty of Medicine, Belgrade, Serbia Department of Humanities Pasterova 2 Serbia, ⁴University of Belgrade, Faculty of Medicine, Belgrade, Serbia Department of Humanities Serbia, ⁵Euro Health Group Serbia, ⁶University of Belgrade, Faculty of Medicine, Belgrade, Serbia Serbia

Background and Objectives: COVID-19 vaccines represent a life-saving solution for the pandemic which has resulted in millions of deaths around the world, but vaccine uptake has remained low in Western Balkan countries. Vaccine hesitancy is the result of a plethora of factors which are usually addressed using general messaging in vaccination promotion strategies. The aim of this study was to identify gender differences in factors influencing vaccine behaviour in the Western Balkans.

Method: This cross-sectional study was carried out from July to October 2021. Convenience sampling included 1605 individuals over the age of 18 from Albania, Bosnia and Herzegovina, North Macedonia, Montenegro and Serbia. The questionnaire was shared online through social media.

Results: Females were more commonly vaccinated in Serbia (73% vs 56%) and Bosnia and Herzegovina (40% vs 28%) while males were more often vaccinated in Albania (56% vs 37%), Montenegro (60% vs 53%), and North Macedonia (74% vs 57%). Statistically significant differences were seen between males and females in responses to questions on vaccine safety ($p<0.01$), vaccine efficacy ($p<0.01$), compulsory vaccination ($p<0.01$), disease comprehension ($p<0.01$), risk of disease and susceptibility ($p<0.01$) and trust in societal factors ($p<0.01$). Statistically significant differences between males and females were also seen in sources of information and health literacy, but these differences varied between Western Balkan countries.

Conclusions: Strategies to combat vaccine hesitancy should take into account the specificities of target populations. General strategies which were applied in most Western Balkan countries were set to fail as they did not address specific factors influencing vaccine hesitancy.

Sex differences in psychosocial and economic impact of covid-19 among migrant origin populations compared with the general Finnish population

Sanna Nykänen¹, Natalia Skogberg², Regina Velázquez³, Anu Castaneda⁴, Päivikki Koponen⁴, Laura Mustajoki³

¹Finnish Institute for Health and Welfare Finnish Institute for Health and Welfare Mannerheimintie 166, PL 30, 00271 Helsinki Finland, ²Finnish Institute for Health and Welfare, Helsinki, Finland, ³Finnish Institute for

Health and Welfare, ⁴Finnish Institute for Health and Welfare Finland

Background and Objective: COVID-19 impacted particularly migrant origin populations. While studies focusing on general populations have reported sex differences in COVID-19, few studies have addressed sex differences in migrant origin populations. This study examines sex differences in psychosocial and economic impact of COVID-19 among migrant origin populations in Finland.

Methods: Data from the Impact of the Coronavirus on the Wellbeing of the Foreign-born Population (MigCOVID) Survey (10/2020-2/2021; $n=3668$) conducted among adults aged 20-66 years was used, with participants in the FinHealth 2017 follow-up study as the general population reference group ($n=3490$). Perceived impact on economic situation, loneliness, hope for the future, contact with friends, and sleeping difficulties were examined. Prevalence rates and their 95% confidence intervals (95%CI) were calculated. Multivariate logistic regression analysis was applied to examine differences by sex, adjusting for sociodemographics.

Results: In preliminary analyses, loneliness increased 37.9% (95%CI 33.8-42.1) of migrant origin women, 33.2% (95%CI 29.2-37.4) of migrant origin men, and 34.8% (95%CI 31.2-38.5) of general population women, and 20.7% (95%CI 17.6-24.3) of general population men. Hope for the future decreased 36.5% (95%CI 32.5-40.6) of migrant origin women, 39.0% (34.8-43.3) of migrant origin men, 35.8% (95%CI 32.3-39.5) of general population women, and 24.3% (21.1-27.8) of general population men. Financial situation worsened 43.3% (95%CI 39.0-47.6) of migrant origin men, 42.0% (95%CI 37.9-46.2) of migrant origin women, 21.5% (95%CI 18.5-25.0) of general population women and 16.0% (95%CI 13.9-18.4) general population men. Logistic regression analyses will be reported in the presentation.

Conclusion: General population women reported greater psychosocial and economic impact than men. Sex differences within migrant origin populations were not significant, although men and women reported significantly higher adverse psychosocial and economic impact compared with men in the general population. Findings with intersectional approach should be used when planning restorative measures to reduce adverse societal impact in future crises.

SARS-CoV2 pandemic and its confrontation in indigenous people: An experience with 34 Brazilian districts

Viviane Lourenço¹, Soraya Andrade², Viviane Lourenço¹, Rodrigo Santana², Augusto Drumond², David Naddler³, Ademir Lapa², Alexandre Pozza²

¹Leader of innovation and digital health Brazil, ²Ministry of health, Brazil Brazil, ³Federal University of Tocantins, Brazil

Background: Studies show that indigenous peoples are more vulnerable to epidemics due to social, economic conditions and access to health, which amplifies the potential for the spread of diseases such as the coronavirus (COVID-19), an infectious disease caused by the SARS-CoV-2.

Objective: To present the Brazilian Government strategy to tackle the COVID-19 in indigenous communities, considering multiple stakeholders.

Methods: Besides communication strategies, this paper also discusses the proposition a repository with contingency plans for specific territorial realities.

Results: The strategies were developed under the Brazilian Governments leadership, with the support of the 34 indigenous districts (DSEI). The types of strategies developed involve policy ordinances, technical reports, reports, recommendations, clinical management protocols, epidemiological bulletins, multidisciplinary actions and a Communication Hub. The Communication Hub has involved social network channels with approximately four hundred thousand accesses, even in regions with difficult internet access. Brazil has continental dimensions and has one of the largest indigenous population in the world; therefore, the Brazilian Government articulated a strategy to ensure that the indigenous people would have access to health, food, security isolation and social benefits.

Conclusions: Features of this reported experience might be exported and adapted to local circumstances elsewhere to prevent widespread mortality in indigenous communities. As suggestions for future research related to fighting COVID-19, we recommend a study divided among health systems in countries with indigenous populations, as well as a study comparing the vulnerability of indigenous populations with general population and misinformation related to indigenous health.

App-based collection of real-world data on the covid-19 pandemic and vaccines in germany 2021-2022

Anna-Lena Lang¹, Vukašin Višćević², Nils Hohmuth³, Stefan Konigorski⁴,

Rasmus Leistner⁵, Cornelius Remschmidt⁶

¹Data4Life gGmbH Germany, ²Data4Life, ³Medizinische Klinik für Gastroenterologie-, Infektiologie-, und Rheumatologie, Charité University Medicine Berlin Germany, ⁴Digital Health Center, Hasso Plattner Institute for Digital Engineering, Potsdam, Germany. Hasso Plattner Institute for Digital Health at Mount Sinai, Icahn School of Medicine at Mount Sinai, New York, USA. Department of Statistics, Harvard University, Ca Germany, ⁵Medizinische Klinik für Gastroenterologie-, Infektiologie-, und Rheumatologie Campus Benjamin Franklin, Charité University Medicine Berlin, ⁶Data4Life Germany

Introduction: The COVID-19 pandemic challenged health systems worldwide to collect data broadly, rapidly, and safely to better understand the virus and respond dynamically to new developments. As new variants require new vaccines, adaptive and scalable study solutions were needed to test vaccine effectiveness (VE) and drug safety under real-world conditions. We investigated the feasibility of a digital study app to collect data on COVID-19 in Germany with a focus on VE.

Methods: In a digital prospective cohort study, we collected self-reported data between May 2021 and April 2022 to assess test-positive rates, incidences, suspected adverse events after vaccination, and VE. We used binomial regression models adjusted for confounders to estimate VE.

Results: A total of 9,592 individuals participated in our study. Incidence and test-positive rates in our cohort reflected the course of the pandemic in Germany. 1,768 unvaccinated participants were compared with 5,368 participants who had received at least two doses of any COVID-19 vaccine and 2,433 participants who had received three doses. Adverse events after vaccination were consistent with previously published research. Preliminary analyses revealed VE against infections across all vaccine brands waning from 89.1% (95% CI 68.2-96.2) at week 4 to 45.5% (95% CI 29.6-57.8) at week 28 after the second dose. Third vaccine dose restored VE to 67.5% (95% CI 53.6-77.1) after 4 weeks. We observed similar preliminary results for two and three doses of the BNT162b2 vaccine.

Conclusion: We successfully tracked the course of the pandemic in the German population using self-reported data from a small, self-selected cohort. Registration of COVID-19 VE with self-reported data in our study app was feasible but presented numerous challenges and potential biases that require further refinement for successful use as a digital public health tool.

The role of ships hospital in pandemic emergences: Public health lessons learnt from the transformation of a ferry in a covid-19 ship hospital

Antonello Campagna¹, Rosa Russo², Paolo Cremonesi³

¹Italian Ministry of Health, Liguria Health Port Authority Via Ribotta 5, Roms Italy, ²Italian Ministry of Health, Liguria Health Port Authority,

³Department of Emergency Medicine, Galliera Hospital Genova Via Mura della cappuccine, Genova (Italy) Italy

During Covid Pandemia ship hospitals (USNS Mercy and USNS Confort) have been employed in the USA to provide medical care. In Europe in March 2020, a long-distance ro-ro ferry (Splendid G.N.V. Company) moored in the port of Genova (Northwest of Italy) was transformed into a medical care facility for COVID-19 in 1 week. The project intended to help infected patients that required low-intensity care, were discharged from hospitals in the Liguria Region and were not yet able to return home. The aim was to share some of the treatment burden of the completely overcrowded local ashore hospitals and to free up bed spaces for patients in the acute phase of the disease.

To the best of our knowledge, this is the only example in the world in which a passenger ship was transformed into a hospital ship for COVID-19 patients in such a short space of time and with such excellent clinical results.

In this work we discuss under the health port authority perspective the public health and the safety issues resulting from the exceptional and very unusual allocation of ashore medical facilities on a passenger ship.

The area for hospitalization consisted of a first module of 27 cabins, followed by a second module consisting of 25 cabins adjacent to the previous one. A common area—the catering zone and fresh air zone—was also set up on the outdoor deck. From 23 March to 18 June 2020, 191 patients were admitted onto the ship with excellent clinical results and no cases of contagion between crew members were recorded.

Conclusions: Use of Ships Hospitals to provide medical care could be an option to consider during pandemic crises under specific conditions.

Impact of lifting COVID-19 restrictions in mental well-being: a quasi-experimental approach

João Santos¹, Teresa Leão²

¹Faculty of Medicine - University of Porto Portugal, ²Faculty of Medicine - University of Porto; Institute of Public Health of Porto University Portugal

Background and objective: Despite the contribution to SARS-CoV-2 dissemination control, lockdown measures severely affected the population's well-being. Previous cross-sectional studies described the prevalence of anxiety and depression symptoms during the pandemic, but longitudinal approaches are needed to understand the impact of implementation and lifting lockdown measures in populations' well-being.

With that purpose, we aimed to assess the impact of lifting lockdown policies in the mental health of the Portuguese population through the COVID-19 pandemic, among different socioeconomic strata.

Methods: We used the Diaries of a Pandemic database – a longitudinal, web-based, and self-administered questionnaire implemented in Portugal in 2020 and 2021. Using data from the weekly reports of fear, sleep disorders, and negative feelings, we performed an interrupted time series analysis using weekly-aggregated data and a longitudinal analysis using individual data. We further compared the effects across different income, education, and caregiver status.

Results: We observed negative trends in the proportions of negative feelings [b2020=-1.02, 95%CI2020=(-1.40;-0.64); b2021=-1.12 95%CI2021=(-1.55;-0.69)], sleep disorders [b2020=-3.65, 95%CI2020=(-4.70;-2.61); b2021=-0.87 95%CI2021=(-1.25;-0.49)], and feelings of fear [b2020=-3.65, 95%CI2020=(-4.70;-2.61); b2021=-0.53 95%CI2021=(-0.78;-0.29)], during both lockdowns, and a statistically significant short-term reduction in the risk of negative feelings in 2020 [b2020=-6.32, 95%CI2020=(-8.33;-4.30)], sleep disorders [b2021=-4.35, 95%CI2021=(-8.10;-0.60)], and feelings of fear in 2021 [b2021=-3.25, 95%CI2021=(-5.47;-1.03)]. Trends became stable after restrictions' lifting in both waves. Results from the individual-data longitudinal analysis reflected those from the interrupted time series analysis with aggregated data, except for reports of fear, where a statistically significant increase after lockdown was observed in 2020. Regarding socioeconomic factors, although most favoured groups had lower proportions of symptoms, trends were overall similar to those observed in the non-stratified sample.

Conclusion: Mental health symptoms became less frequent during the 2020 and 2021 COVID-19 waves and its frequency was affected by the lifting of lockdown measures, globally and across socioeconomic groups.

Long-covid experience and perceptions among primary care practitioners in germany - results from a nation-wide online-survey 2022-2023

Salma Mekkes¹, Lorena Dini², John Gubernath³, Giselle Sarganas³, Christa Scheidt-Nave⁴, Sydney Odonkor⁵, Juliette Schreiber⁶

¹Charité Universitätsmedizin Berlin Germany, ²Charité Universitätsmedizin Berlin EUPHA Germany, ³Robert Koch Institute Germany, ⁴Robert Koch Institute Germany, ⁵Charité Universitätsmedizin Berlin, Institute of General Practice, ⁶Charité Universitätsmedizin Berlin, Institute of General Practice Germany

After the onset of the COVID-19 pandemic, a growing number of patients began to report prolonged COVID-19 symptoms lasting for more than four weeks after infection (Long COVID). These symptoms include among others, fatigue, difficulty concentrating, respiratory, cardiovascular, and metabolic issues, which cannot be explained by other causes. Persistence or reappearance of these symptoms often persist over more than three months. Lasting symptoms are diffuse and may vary depending on severity of SARS-CoV-2 infection, comorbidities, SARS-CoV-2 vaccination status, gender, age or circulating virus strain, among others. Most of these patients are seen in primary care and this problem has been increasing. Because patients with Long COVID are not considered a source of infection to others, there is no mandatory reporting to public health authorities, making the surveillance and monitoring of this condition more difficult. Clinical management guidelines are being discussed and there is still a lack of a harmonized definition and a clear patient referral pathway. Adding to the direct pathophysiological effects of the SARS-CoV-2 infection, the indirect effects such as the consequences of the pandemic-containment-measures is also leading to a higher psychosocial and economic burden for these patients and the society. In many countries national public health authorities are working towards assessing Long COVID from multiple perspectives including building alliances and networks with different stakeholders including primary care providers, rehabilitation clinics and patients' self-help groups.

This presentation is meant to share the results from the Germany about the experiences and expectations on the management of Long COVID including of the (expected and potential) impact on primary care, public health including how can risk factors, prevention, health care, management and rehabilitation be supported by informed based health policy amongst primary care physicians.

Sulodexide as a promising treatment of post COVID 19 symptomatic patients with endothelial dysfunction

Ahmed Makni¹, Aimen Ghrab², Salma Charfeddine¹, Slim Torjmen¹, Hassen Hadjamar³, Kamal Bouslama⁴, Sami Milouchi⁵, Salem Abdessalem⁶, Leila Abid¹

¹Cardiology department, Hedi Chaker University Hospital Sfax, Tunisia, ²Cardiology department, Habib Bourguiba Hospital Medenine, Tunisia, ³Cardiology department, Tahar Sfar Hospital Mahdia, Tunisia, ⁴Internal medicine department, Mongi Slim LaMarsa Hospital, Tunis, Tunisia, ⁵Cardiology department, Habib Bourguiba Hospital Medenine, Tunisia, ⁶Clinic Pasteur Tunis, Tunisia

Background: It is established that COVID 19 infection causes endothelial dysfunction resulting in most of its acute symptoms and its long-term effects also known as post covid-19 syndrome.

Aim: The aim of the study was to evaluate the effect of Sulodexide, a purified glycosaminoglycan mixture, in the improvement of the endothelial function due to long COVID 19 syndrome.

Methods: We conducted a multicenter Tunisian prospective quasi-experimental analysis from the large TUN End-COV trial. Patients with long COVID-19 symptoms and endothelial dysfunction were included. The subset of symptomatic patients with proven endothelial dysfunction (Endothelial Quality Index (EQI)<2) assessed by a post-occlusive reactive hyperemia (PORH) finger thermal monitoring (E4-diagnose, Polymath Company) were assigned into two groups. The sulodexide group received sulodexide (Vessel, AlfaSigma) 250 RLU twice a day during 21 days. The control group adhered to the study protocol without any medical treatment. **Results:** A total of 290 patients from TUN End-COV study with long COVID-19 symptoms and endothelial dysfunction were included. The study population was assigned to a sulodexide group (144 patients) or a no-medical treatment group (146 patients). Clinical characteristics were similar at inclusion in the two groups. The sulodexide group presented significantly less chest pain and palpitations than controls ($p<10^{-3}$ and $p=0.009$ respectively). The sulodexide group presented also a significant endothelial function amelioration compared to control group (median delta-EQI 0.66 (0.6) vs 0.18 (0.3); $p<10^{-3}$). Endothelial function improvement was significantly correlated to chest pain and palpitations recovery (AUC = 0.66, CI = 0.57- 0.75, $p = 0.001$ and AUC =0.60, CI = 0.51- 0.69, $p = 0.03$ respectively). **Conclusion:** Our results support that sulodexide may accelerate long COVID 19 patients' recovery in parallel with vascular endothelium restoration.

Physical activity promotes social relationships during "lenient" COVID19 protection strategies

Mahmoud Alomari¹, Khaled Alshaji², Ahmed Al-Emadi³

¹Jordan University of Science and Technology Department of Rehabilitation Sciences; Jordan University of Science and Technology POBox 3030 Department of Rehabilitation Sciences; Jordan University of Science and Technology Irbid, Jordan 22110 Jordan, ²College of Basic Education, PAAET Khalid Bibi Qatar University Department of Physical Education, Qatar University Department of Physical Education, Qatar University, Doha, Qatar 2713. Qatar, ³Qatar University Department of Psychological Sciences, Qatar University Department of Psychological Sciences, Qatar University, Doha, Qatar

Background and objective: During COVID19 outbreak, many governments worldwide shutdown public places including gyms, schools, universities, colleges, workplaces, and malls. These COVID19-induced procedures limited participating in physical and social activities immensely. In Qatar, however, the government allowed outdoor physical activities only with family members. The effect of such "lenient" COVID19 confinement procedures on physical and social activities is not known. Therefore, the current study examined the association between changes in physical activity and social relationships during COVID19 lockdown in Qatar.

Methods: The changes in physical and sedentary activities and social relationships during COVID19 were collected from 488 Qataris (mean age=26.9±9.6 years) using an online survey.

Results: The participants reported an increase in physical and sedentary activities

during versus before the pandemic. Further analysis revealed that this increase was reported among the participants who experienced improvement or no change in the relationship with spouses, children, parents, siblings, uncles, neighbors, work colleagues, and overall relationships. However, the participants reported worsened social relationships experienced no increase in physical activity during the pandemic.

Conclusion: The results show that "lenient" COVID19 regulations contribute to enhancing participation in physical activities. Uniquely, this increase is associated with improvement in social relationships. These results might suggest that participating in physical activities can help "mitigate" the possible deterioration in social relationships due to pandemic-induced confinement. Therefore, efforts should be made to promote physical activities during pandemic breakouts to protect the welfare of the social relationship. However, future studies are needed to confirm the current findings and verify these speculations.

The experience of the covid-19 pandemic in fortaleza, Brazil: Public health in turmoil?

Carl Kendall¹, Ligia Kerr²

¹Tulane University Visiting Professor, Federal University of Ceará Programa de Pós-Graduação em Saúde Pública Universidade Federal do Ceará, Fortaleza, Brasil, ²Federal University of Ceará, Brazil

Background: While the title and goal of our conference is a positive response to having lived through the last three years of an infectious disease pandemic that we were promised as recently as the 1980s was part of the world's past – is public health in any condition to respond? Staff burnout, cuts in health budgets, low vaccine coverage, and a public fatigued with everything but new conspiracy theories and targets to blame is not a propitious start. While technological advances in rapid home tests, vaccines, antivirals, and surveillance methods were brilliant achievements and saved millions of lives, the behavioral and social sciences contributed relatively little to policy and program, and only a few national programs appear to have achieved transmission control goals. This presentation reviews public response to testing, isolation, vaccination, distancing, and mask use in the northeast state of Ceará.

Methods: Ethnographic case study applying formative research with expert and lay interviewees. A desk review of relevant published and unpublished information describes the chronology of response events, cases, and deaths attributed to COVID-19. Means of promoting recommendations, evaluating responses, and interactions among health authorities and political leaders will be described.

Results: Early efforts (spelled out in the paper) were successful at slowing epidemic spread and deaths, with little of the animosity experienced in other regions of Brazil. High levels of collaboration among health professionals and political authorities were achieved. As awareness of the magnitude of the pandemic grew, national and international coordination was required to sustain a response. Absent this, local political, rather than epidemiologic facts determined the next steps. Without an effective national response individuals calculated their own risk and acted accordingly.

Virtual mourning, the experiences of iranian diaspora during COVID-19

AHMADI Ali¹, Ali Ahmadi²

¹BPH Bordeaux, University of Allameh Tabatabai France, ²BPH Bordeaux, University of Allameh Tabatabai France

With the onset of the COVID-19 pandemic, the phenomenon of mourning was marked worldwide by an unprecedented disruption of family visits not only for migrants living abroad, who were confronted with the closure of borders, but also for all family members who lived in the same city. In such a situation, the evolution of funeral rites and commemorations was more and more evident: visiting relatives at the end of life and seeing the deceased before death being impossible, burial ceremonies and almost all commemorations were restricted in order to respect the social distancing. Given the unprecedented ban on mourning ceremonies, social networks, and later special sites tailored to Iranian culture and rituals, became places for families of the deceased perform funeral and mourning rites. Thus, microblogging platforms have made it possible to invent ritual practices and to extend this process of expression to migrants.

The objective of this research is to understand the processes of distance mourning in migration by studying the experience of the Iranian diaspora in France and to discover the characteristics of virtual mourning. To achieve this objective, observation of social media and virtual mourning platforms and semi-structured

interviews were conducted. This study shows that migrants who are unable to attend the mourning ceremony of their family members for various reasons, including asylum or restrictions of the COVID-19, attempt to fill this gap by using social networks and communication platforms. According to this study, online platform is a place to meet and visit families after a long time but there are some limits such as not being able to hug and cry with family members and inability of emotional emojis for express feelings. Online grieving is an opportunity to move from intrapersonal to interpersonal communication that may facilitate the completion of grieving tasks.

Overdose deaths and the covid-19 pandemic in british columbia, canada

Heather Palis¹, Amanda Slaunwhite¹, Marc-Andre Belair², Kevin Hu¹, Andrew Tu³, Jane Buxton⁴

¹BC Centre for Disease Control Canada, ²PHAC, ³BC Coroner Service Canada, ⁴BC Centre for Disease Control

Background: British columbia (bc) declared an overdose public health emergency in 2016. Since then, bc has consistently reported the highest overdose death rates of any province in canada. In the context of the covid-19 pandemic, overdose deaths in bc reached a record high in 2020. This analysis reports on changes in the profile of people who have died of overdose since bc's declaration of covid-19 as a public health emergency on march 17th 2020.

Methods: Using bc coroners service data, chi-square tests and multivariable logistic regression were conducted to compare demographic, geographic, and post-mortem toxicology data between people who died of overdose before (march 17th- december 31st 2019) and after (march 17th- december 31st 2020) bc's declaration of covid-19 as a public health emergency.

Results: Overdose deaths observed since march 17th 2020 (n=1516) more than doubled those observed in the same period in 2019 (n=744). In the adjusted logistic regression model, odds of death in the post compared to pre-covid-19 period was significantly higher among males compared to females, among all older age groups compared to people aged 30-39, and was higher outside compared to in private residences.

Conclusions: Alongside a significant increase in overdose deaths, the demographics of people who have died of overdose has changed since march 2020. Ongoing overdose prevention efforts must seek to reach people who remain most isolated, including older adults, who during dual public health emergencies are facing compounded risk of preventable mortality.

Physiology, Infectiology and Public Health, Ghent University, Merelbeke, Belgium, ¹²Universidade de Lisboa Instituto de Saúde Ambiental, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal / Área Disciplinar Autónoma de Bioestatística, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal, ¹³Instituto de Salud Carlos III, REDISSEC and RICAPPS National Center of Epidemiology, Instituto de Salud Carlos III, REDISSEC and RICAPPS, Madrid, Spain

Background and Objective: There is growing evidence on the role of biomedical factors and socioeconomic status in increasing vulnerability to COVID-19. We conducted a systematic review to investigate the etiological and prognostic roles of multimorbidity, frailty and socioeconomic determinants in COVID-19 outcomes severity among population-representative samples. This presentation focuses on socioeconomic determinants.

Methods: The following databases were searched: PubMed, Embase, WHO COVID-19 Global literature on coronavirus disease and PsycINFO between January 2020 and 7th April 2021. For the etiological role of socioeconomic determinants, the following outcomes were of interest: infection, hospitalisation, ICU admission, mechanical ventilation and mortality. For the prognostic role, we investigated hospitalization for COVID-19, ICU admission, mechanical ventilation, death, functional decline, quality of life, disability, mental health difficulties, work absence.

Results: Out of 9 701 reviewed titles and 411 articles read in full-text, 78 studies reporting on socioeconomic characteristics met the eligibility criteria and were included in the final synthesis. 47 studies reported on the etiological role, 24 studies reported on the prognostic role, and 7 reported on both. No studies reported on long term effects of socioeconomic determinants. Only short term COVID-19 related outcomes, such as COVID-19 infections, mortality, ICU admission, hospitalization etc. were identified. Data was often retrieved using administrative and hospital records. The evidence suggests that worse health outcomes were often seen in black and Asian populations, and associated with lower education level and higher deprivation score. Most of the studies cover populations in the United States and the United Kingdom.

Conclusions: The risk of severe short-term COVID-19 outcomes increase with socioeconomic vulnerability and among certain ethnic groups. There is a need for more evidence on the role of socioeconomic characteristics in short-term and long-term COVID-19 outcomes in other European, Asian and African countries. Future research should target specific races and ethnic groups.

DOI: 10.18332/popmed/164517

Interviewing the interviewers: capturing oral histories and other qualitative evidence to describe the impact of covid-19 contact tracing

Anita Apau¹, Perri Carrol², Sarah Linden³, Marcia Pearlowitz⁴, Katherine Feldman⁵

¹Maryland Department of Health 101 E Mount Royal Avenue, Apt 703. Baltimore -Maryland United States Maryland Department of Health Johns Hopkins Bloomberg School of Public Health 101 E Mount Royal Avenue, Apt 703. Baltimore-Maryland. United States, ²Johns Hopkins Center for health and Equity, ³Maryland Department of Health "201 W. Preston Street. Baltimore- Maryland" United States, ⁴Maryland Department of Health 201 W. Preston Street. Baltimore-Maryland United States, ⁵Maryland Department of health

Background and Objective: Contact tracing was a crucial component of the public health response to prevent the spread of COVID-19, albeit a time-consuming activity requiring many human and technical resources. Maryland contact tracers provided vital assistance to COVID-19 patients and close contacts. The purpose of this evaluation was to capture qualitative aspects of COVID-19 contact tracing to document impact (e.g., stories describing experiences contact tracers had while interacting with cases and close contacts).

Methods: We conducted semi-structured qualitative interviews with 14 contact tracers from various counties in Maryland via videoconference. We collected information about why they became contact tracers, explored the impacts they had on cases and close contacts, and captured the memorable experiences, challenges, and rewarding parts of contact tracing. Themes and quotes were manually coded from interview transcripts and analyzed manually using the classic method of qualitative data analysis.

Results: Data analyses revealed themes including altruism, being a source of support, being overwhelmed, satisfaction in closing cases, and interest in continuing a career in public health. Most participants indicated they became contact tracers to help fight the pandemic. Contact tracers recalled experiences of calling 911 for clients over the phone and sometimes being the last and only

person to speak to clients before they died. Many were overwhelmed with the large number of cases they had to call daily but found it rewarding to notify cases and close contacts to end isolation or quarantine. And those new to the field indicated they were now interested and wanted to stay in public health.

Conclusion: We documented the qualitative impact of contact tracing not captured in the contact tracing and disease surveillance metrics. The testimonials can be used to improve contact tracing processes and policies for future pandemics and to inspire the next generation to join the public health workforce.

Popul. Med. 2023;5(Supplement):A464

DOI: 10.18332/popmed/164304

Risk of sars-cov-2 reinfection in sicily: A population-based evaluation of covid-19 events using current health databases

Dario Genovese¹, Domenica Matranga², Laura Maniscalco¹, Vincenzo Pisciotta¹, Giuseppe Vella², Alessandra Casuccio¹, Emanuele Amodio¹
¹University of Palermo Department of Health Promotion, Mother and Child Care, Internal Medicine, and Medical Specialties "G. D'Alessandro" Via del Vespro, 133 - Palermo (PA) Italy, ²University of Palermo

Background and Objective: Worldwide, the COVID-19 outbreak resulted in more than 640 million cases as of 15 December 2022. As immunity to natural infection deteriorates with time and SARS-CoV-2 strains mutate, reinfections began to occur. The current study sought to assess the probability of SARS-CoV-2 reinfection among residents of Sicily, Italy, in relation to sex, age, number of mRNA COVID-19 vaccine doses administered, and occurrence of hospitalization during a previous infection.

Methods: A population-based retrospective cohort analysis was designed using the Sicilian COVID-19 monitoring system run by the National Institute of Health and vaccination flows acquired through a regional registry in Sicily. Only Sicilian adults were included in the study, and hazard ratios were calculated using Cox regression.

Results: After an average of 198 days, there were 39,509 reinfections among 1,089,782 previously infected people (overall cumulative incidence: 3.62%) from the start of the pandemic to 3 September 2022. Almost all reinfections (37,084; 93.9%) occurred during the Omicron variant period, with the remaining 6.1% attributed almost entirely to the period in which Delta and Omicron variants co-circulated (2,011; 5.1%). The risk of reinfection was significantly lower among males than females (HR:0.74, 95%CI:0.73-0.76), decreased with age (from HR:1.24, 95%CI:1.20-1.28 for 30-39 years old people to HR:0.36, 95%CI:0.33-0.38 for 80+ individuals compared to 18-29 group), and lower for people receiving two or more mRNA vaccine doses (HR:0.39, 95%CI:0.38-0.40 compared to the individuals who did not receive vaccination). Interestingly, those who were hospitalized during their previous SARS-CoV-2 infection exhibited a significantly lower chance of reinfection (HR:0.74, 95%CI:0.70-0.78).

Conclusion: SARS-CoV-2 reinfection was found to be a relatively common occurrence, predominantly caused by the Omicron strain. COVID-19 vaccination provides significant protection against reinfection. Furthermore, the lower risk observed in the elderly and previously hospitalized persons reflects more stringent adherence to the use of personal protective equipment.

COVID-19 travel restrictions and Mongolians stranded abroad: mental health, discrimination, and social inequality

Javkhlanbayar Dorjdagva¹, Javkhlanbayar Dorjdagva², Enkhjargal Batbaatar³, Jussi Kauhanen⁴

¹Institute of Public Health and Clinical Nutrition, University of Eastern Finland Finland, ²University of Eastern Finland Institute of Public Health and Clinical Nutrition "Faculty of Health Sciences, University of Eastern Finland Kuopio Campus, Yliopistonranta 1 FI-70211 Kuopio, Finland, ³University of Eastern Finland, ⁴University of Eastern Finland Institute of Public Health and Clinical Nutrition "Kuopio Campus, Yliopistonranta 1 FI-70211 Kuopio, Finland

Introduction and Objective: Since the early stage of the COVID-19 pandemic, the government of Mongolia has taken strong measures, including border restrictions to protect its citizens from COVID-19. The border to all passengers, including Mongolians, was closed on March 11, 2020. Consequently, thousands of Mongolians were stuck abroad for months and faced enormous risks.

The aim of this study was to evaluate the mental health and financial situation of Mongolians who were stuck abroad due to COVID-19 during their temporary travels and to support public health policymakers to make quick responses to save lives. Methods: The data was collected between April 27 and May 4, 2020 through an online Google form survey. A total of 118 Mongolian citizens stranded abroad

during their temporary travels due to COVID-19 from 25 different countries completed the questionnaire. The policies and regulations for evacuation flights for Mongolian citizens were reviewed in this study.

Results: The study participants travelled abroad for tourism, medical, family, training, and business purposes. The majority of the participants reported that they felt discrimination and anxiety, and faced financial difficulties in the stranded countries.

Language barriers, visa expiration, chronic diseases, and a lack of knowledge of the corona virus among the participants, and a limited number of evacuation flights have increased the uncertainty. Lower-income people might have been left behind not affording the high price of evacuation flight tickets and quarantine costs.

Conclusion: The Mongolians who were stuck abroad due to COVID-19 and border closure had greatly suffered mentally and financially. We recommended the government to provide financial aid, and online mental and health services for those in need. These aids from the government should be included in the support packages for citizens stranded abroad as pandemic preparedness for future pandemics. Ensuring equality during the process of evacuation is essential.

Using the ophelia process with marginalised communities during covid-19 crisis

Shandell Elmer¹, Richard Osborne¹

¹Swinburne University of Technology 453/469-477 Burwood Road, Hawthorn, Australia Australia

Background and objective: In August 2021, Melbourne (Australia) entered another period of lockdown and restrictions in response to the COVID-19 pandemic. Messages about vaccinations and other COVID-safe behaviours were not reaching everyone because people's particular health literacy needs were not considered. People experiencing vulnerability and disadvantage, such as those living in social and public housing were most at risk. This research aimed to develop a granular understanding of the experiences and health literacy needs of people residing in these settings to optimise communication and engagement for COVID-19 prevention and safety.

Methods: The Ophelia (Optimising Health Literacy and Access) process, a participatory community-based method, was chosen for this research project to accelerate the generation and deployment of fit-for-purpose interventions. Community engagement processes included approaches through trusted local entities, incentives, and repeat targeting (with incremental trust development). Postcards were disseminated to recruit people for an online or phone survey. Doorknocking occurred in tandem with service providers to conduct the survey face-to-face. The research team also attended community events such as pop-up vaccination hubs. Sixteen workshops were held with 4 teams of health workers and weekly sense-making meetings were held over 9 months with executives from 5 health services.

Results: 865 people participated from public and community housing, rooming houses, caravan parks, supported residential services, disability services and homeless hotels. Overall, their health literacy was much lower than national average. Fifty vignettes of typical residents were developed, and these then elicited >400 rapid practice solutions for health workers and managers to implement.

Conclusion: The combination of COVID-19 related and other variables provided insights into the mechanisms required to inform and generate context-specific interventions. This is important, because it is this diversity that helps us understand why public health messages and engagement strategies, designed to reach the average person, can leave so many behind.

Capacity-Building for Complex Crises: Developing public health leadership and meeting decision-makers' evidence needs

Emilie McSwiggan¹, Marshall Dozier², Rowa-Dewar Neneh², Gwenetta Curry², Evropi Theodoratou², Ruth McQuillan², Agyei-Manu Eldad³, Thulani Ashcroft¹, Nadege Atkins¹, Emma Birley³, Udani Silva³, Kirsten Duggan⁴, Emma de los Godos⁵, Damilola Iduye⁶, Prerna Krishan⁶, Durga Kulkarni², Bohee Lee², Ashmika Motee², Madhurima Nundy⁷

¹Uncover, University of Edinburgh United Kingdom, ²University of Edinburgh United Kingdom, ³Uncover, University of Edinburgh, ⁴Uncover, University of Edinburgh Germany, ⁵Uncover, University of Edinburgh Denmark, ⁶Uncover, University of Edinburgh Canada, ⁷Uncover, University of Edinburgh India

Background/objective

Uncover is a global network of academics and students, based at the University

of Edinburgh, providing rapid evidence syntheses for decision-makers. Founded in response to COVID-19, UNCOVER now also addresses other complex real-world challenges with a public health dimension, from emerging infectious diseases to climate change. Despite starting as an urgent crisis response, UNCOVER has always taken a reflective, collaborative approach to its own methods and practices. This has shaped our critical focus on capacity-building – in order to meet decision-makers' evidence needs today and to prepare the public health leaders of the future – which may provide useful insights to others with similar priorities.

Methods: Uncover has taken various formal and informal approaches to understanding what works and identifying improvements. Among these, key initiatives include: * Staff-led qualitative interviews with staff and student volunteers, carried out in the early months of UNCOVER's existence; * An in-depth qualitative study carried out by UNCOVER student members in 2021; * A 2022 workshop with student members, exploring how UNCOVER has contributed to their learning and development; * After-Action Reviews of some UNCOVER projects.

Results: Uncover's working model contributes to four different dimensions of public health capacity-building, by bridging gaps between: * NOVICES AND EXPERTS: Providing meaningful opportunities for applied, collaborative work, with a focus on nurturing and developing students' skills; * DISCIPLINES: Developing tools and resources which support common understanding and knowledge translation between disciplines, with an emphasis on quality and rigour; * ACADEMIA AND POLICY: Building partnerships with decision-makers and prioritising real-world questions; * COUNTRIES: Creating a wholly online community, with a global membership, in which all community members bring valuable insights and knowledge.

Conclusion: Uncover's working model may provide some useful insights for others with an interest in public health capacity-building, with a twin focus on addressing the challenges of today and preparing the leaders of tomorrow.

Intensive care unit hospitalizations and outcomes among patients with severe covid-19 in gauteng province, south africa

Harsha Somaroo¹

¹Public Health Association of South Africa WITS School of Public Health South Africa

Background and objective: Gauteng Province was the South African epicentre during the coronavirus disease 2019(COVID-19) pandemic and subsequently experienced high rates of severe COVID-19 cases and hospitalisations, including intensive care unit(ICU) admissions. ICU beds are a scarce and costly resource in South Africa, and the increased demand and utilization during the COVID-19 pandemic provided an opportunity for further analyses to potentially inform future patient management and ICU policies.

Methods: A retrospective, observational, cohort study was conducted using COVID-19 hospital surveillance data for Gauteng. Demographic and clinical factors were described. Predictors of mortality were determined using logistic regression analyses.

Results: Of the 158737 patients hospitalised with COVID-19 from 6/03/2020 to 27/11/2022 in Gauteng, 8.8%(n=13907) were admitted into an Intensive Care Unit(ICU). Of these patients, 56.0%(n=7784) were male and 67.1%(n=9337) were aged 50 years and over. Using national, official definitions for COVID-19 waves, the last(fourth) wave in Gauteng ended on 31/12/2021. A total of 8796 patients were admitted into ICUs during all four COVID-19 waves in the province. The majority of ICU admissions[38,5%;n=3386] occurred during the third wave(27/05/2021-11/08/2021), when the SARS-CoV-2 Delta variant was the predominantly circulating viral strain. Most ICU admissions were into private-sector hospitals[88.6%;12316]. 5465(39.3%) of ICU admissions received mechanical ventilation, of which 83.5%(4561) was in private-sector facilities. 7588(54.6%) patients received supplemental oxygen therapy. Statistically significant (p-value <0.05) risk factors for mortality included older age; comorbid hypertension, diabetes mellitus, or active tuberculosis; and mechanical ventilation. Supplementary oxygen was protective against mortality.

Conclusion: The majority of ICU admissions for COVID-19 in Gauteng were into private-sector facilities, and less than 40% of these patients received mechanical ventilation. Additional analyses of outcomes observed, and further related research, is important to determine whether improved hospital efficiencies could be achieved. This could also inform future COVID-19 policy and planning decisions within the complex ICU environment.

Learning from the COVID-19 pandemic response to strengthen undocumented migrant-sensitive health systems: case studies from four countries

Eleonora Genovese¹, Kathleen Page², Johann Cailhol³, Yves Jackson⁴

¹University of Milan-Bicocca Italy, ²Johns Hopkins University, ³Université Sorbonne Paris Nord, Bobigny France, ⁴University of Geneva Switzerland

Background and objective: Undocumented migrants are among the most vulnerable in the COVID-19 pandemic. The study objective is to identify lessons learnt to strengthen migrant-sensitive health services and systems.

Methods: Review of empirical observations by clinicians and public health practitioners, peer-reviewed journals, and grey literature analyzed through country case studies (Italy, Switzerland, France, US) on the Governance, Service Delivery, and Information building blocks of Health Systems.

Results: Governance: Some countries expanded COVID-19 health services and alleviated immigration concerns, but implementation varied at sub-national level due to lack of specific migrant-sensitive provisions in policies, plans, and programs. Service delivery: Implementing outreach, engaging migrant communities, and integrating third sector actors are key elements to improve accessibility and uptake of health services including vaccination. Yet, these mostly operated through fixed delivery strategy, while targeted outreach through mobile clinics and outposts is more effective for people on the move. Socio-culturally sensitive information for risk communication was not developed, translated, and disseminated through the most used sources such as community networks. Authorities did not engage migrant communities and third sector actors as key partners with capacity and access. Information: Information about undocumented migrants' health is mostly based on ad hoc surveys at selected health facilities, while there is a lack of systematic monitoring and evaluation with collection and analysis of migrant-specific data.

Conclusion: Migrant-sensitive health services including vaccination are essential for public health. Yet, ad hoc approaches resulted in low and inequitable coverage, besides lacking information for monitoring and evaluation. Health Systems can be strengthened by: (1) learning from the COVID-19 pandemic response, (2) evaluating sustainable policy and financing changes, (3) sustaining multistakeholder partnerships, (4) expanding community engagement, (5) strengthening the health workforce, (6) developing systematic monitoring and evaluation of undocumented migrants' data, (7) consider migration, including undocumented status, as a social determinant of health.

Socioeconomic inequalities in vaccination against COVID-19 in Ecuador

María Rivadeneira¹, Eulalia Torres², Maribel Moreno²

¹Pontificia Universidad Católica del Ecuador PhD, MD Ecuador, ²Pontificia Universidad Católica del Ecuador Ecuador

Introduction: In January 2021, Ecuador began the administration of vaccination against COVID-19 following a staggered and phased process. It is necessary to identify gaps in vaccination coverage that could be related to the presence of future outbreaks of the disease.

General objective

Analyze the socioeconomic gaps in relation to vaccination against COVID-19, in the five of the most important cities in Ecuador: Quito, Guayaquil, Cuenca, Ambato and Machala Methodology: Analytical cross-sectional study, based on secondary data from the National Employment, Unemployment and Underemployment Survey (ENEMDU) that included a vaccination component against COVID-19 in 2021. Data from 91,169 surveyed people were included (with factor of proposed expansion 17,917,508 people). Poisson regressions were performed for complex samples, with crude and adjusted analysis.

Results: The coverage of the second dose reached percentages from 30.2% to 85.5% in the five cities studied. Significant differences were found in vaccination coverage by area of residence (Prevalence Ratio, PR, 0.51, 95% CI 0.45-0.55 for rural vs. urban areas), ethnicity (indigenous PR 0.21, 95% CI 0.19-0.23=, education (PR 0.05, 95% CI 0.03-0.09 for illiterates compared to higher level), income (PR 0.27, 95% CI 0.17-0.43 for those who earn less than USD 400, compared to those who earn USD 1,600 or more). significance was maintained after the adjusted analysis.

Conclusions: There are socioeconomic inequalities in vaccination coverage against COVID-19 in Ecuador. It is necessary to strengthen vaccination in rural and indigenous populations and in sectors with scarce economic resources, as well as establish policies and strategies that ensure timely access to vaccination for the entire population, including more specific strategies for vulnerable populations.

Popul. Med. 2023;5(Supplement):A471

DOI: 10.18332/popmed/164591

Developing the individual capacity, the sense of health responsibility of hacettepe university faculty of education undergraduate students in the novel coronavirus disease (covid-19) struggle

Ali Korkmaz¹, Dilek Aslan¹¹Hacettepe University, Faculty of Medicine, Department of Public Health Turkey

It was aimed to evaluate the knowledge, the adaptation to preventive behaviours, the sense of health responsibility about COVID-19 and to contribute to the development of the capacity of the Hacettepe University Faculty of Education students to fight against the disease through health education.

In this educational intervention study, the intervention was carried out for two weeks with a total of eight hours. Before and after the intervention, pre-test and post-test were applied and the targeted differences, that were in line with the aims of the study, were determined. The data collection form was created by the researchers and the "Fear of COVID-19 Scale" and "Attitudes Towards the COVID-19 Vaccine" were used. SPSS 23.0 was used for the analysis. Ethics committee approval and other relevant official permissions were obtained.

73.1% of all 245 participants were women and the mean age was 21.76±2.76. 79.2% of the participants had never had COVID-19 disease, 98.8% had at least one dose of COVID-19 vaccine, and 51.4% had vaccine hesitancy before being vaccinated. When some capacities of the participants were compared between the pre-test and post-test, statistically significant results were found in fear scale scores ($p<0.001$), in disease knowledge scores ($p<0.001$), in infodemic scores ($p<0.001$), in ability to distinguish high and low quality health resources on the internet ($p<0.001$) and in attitudes towards COVID-19 vaccine ($p<0.001$).

In terms of protecting their own health and their students' health, it's important to increase the capacity of teacher candidates to fight against COVID-19. It's also important for them to learn and develop these through health promotion activities before their graduation so they can perform the skills which are expected from them. In this research, it's been proven that health education intervention can be beneficial. In matters concerning public health, intersectoral cooperations and joint works are important.

DOI: 10.18332/popmed/164594

Changes in behavioral cancer risk factors during the covid-19 pandemic: an umbrella review

Jayati Khattar¹, Laura Anderson², Jayson Habib², Kiara Pannozzo², Nicolette Christodoulakis², Jayati Khattar², Laura Anderson²¹khattarj@mcmaster.ca Canada, ²McMaster University, Canada

Background and objective: The COVID-19 pandemic significantly impacted behaviours and activities of daily life worldwide. Public health restrictions that were necessary to control the virus resulted in changes in health behaviours. This includes changes in established cancer risk factors, defined for this review as smoking, alcohol consumption, decreased physical activity, increased sedentary behavior, decreased consumption of fruits and vegetables, and increased red meat/meat intake. The objective of this umbrella review was to assess how the COVID-19 pandemic, compared to pre-pandemic, impacted the prevalence of behavioral cancer risk factors among community-based adults.

Methods: On October 12th 2022, five databases (PubMed, Web of Science, MEDLINE, Embase and the Cochrane Database of Systematic Reviews) were searched onwards of January 2020. Studies were eligible for inclusion if they were a systematic review, with or without meta-analysis, and if they examined the change in an identified cancer risk factor during the COVID-19 pandemic. Studies were excluded if they did not focus on the general adult population. Five reviewers independently assessed the studies for eligibility, extracted data and conducted critical appraisal using the AMSTAR-2.

Results: After screening, 31 reviews were included for smoking ($n=3$), alcohol ($n=9$), physical activity ($n=14$), sedentary behaviour ($n=8$), fruits and vegetables ($n=6$), and red meat/meat ($n=5$). Preliminary results based on low quality heterogeneous evidence did not suggest a consistent increase in smoking and alcohol use. Similarly, the evidence was mixed regarding fruit, vegetable and red meat/meat consumption and was dependent on study population. In contrast, the evidence consistently indicated a decrease in physical activity and an increase in sedentary behavior during the pandemic compared to the pre-pandemic period.

Conclusions: The results of our review suggest the COVID-19 pandemic had a mixed impact on cancer risk factors. Public health interventions should concentrate on mitigating negative consequences of changes in cancer risk post-pandemic.

Risk of covid-19 spread by undiagnosed cases in inpatients at a large tertiary hospital: transmission dynamics and learnings of two-year experience of surveillance (2020-2022)

Lourdes Barón Miras¹, Blanca Torralbo¹, Isabel Torá-Rocamora¹, María Bertrán-Luengo¹, Antoni Trilla¹, Gemina Santana¹, Isabel Fortes¹, Laura Rodríguez¹, Silvia Valls¹, Juan Gualda-Gea¹, Marta Tortajada¹, Anna Vilella-Morató²

¹Hospital Clínic de Barcelona (1) Department of Preventive Medicine and Epidemiology, Hospital Clínic of Barcelona; (2) Instituto de Salud Global (ISGlobal); Spain, ²Hospital Clínic de Barcelona (1) Department of Preventive Medicine and Epidemiology, Hospital Clínic of Barcelona; (2) Instituto de Salud Global (ISGlobal); (3) Department of Medicine and Health Sciences, Faculty of Medicine, Universitat de Barcelona (UB) Spain

Hospital-Onset COVID-19 Infection (HOCI) encloses still a major risk of transmission and morbimortality, threatening regular activity. The aim of this study is to compare the dynamics of transmission of HOCI of patients attended along the pandemic. This observational longitudinal study included all COVID-19 cases identified, by polymerase chain reaction or rapid antigen tests, in a large tertiary hospital in Barcelona, Spain, between February 25, 2020 and March 25, 2022. HOCI cases were diagnosed either by symptoms or weekly screening during admission, and therefore isolated. Cases and their in-hospital contacts were followed-up. Six periods were defined according to Barcelona's COVID-19 incidence waves. Serial intervals and secondary attack rates (SAR) were calculated, comparing SARs by incidence rate ratios (IRR) between periods and by other clinical and epidemiological factors, using negative binomial regression. From the 11,752 COVID-19 cases attended, 531 (4.5%) were HOCI cases, which fluctuate with community incidence. Morbimortality decreases along time (18% and 11.4% reduction in ICU admission and deaths rates, respectively). Contacts ($n=1976$) were identified in rooms (12.9%) and other settings. Series interval reduces, from a median (IQR) of 4.0 (1.5-6.5) to 3.0 (1.5-4.5) days in the last period. Global SAR is 11.0 cases/100 contacts, reaching 26.8 cases/100 contacts when sharing room, the main factor affecting SAR (IRR 1.8; 95%CI 1.5-2.3). Vaccination did not significantly influence transmission (IRR 0.8; 95%CI 0.7-1.0). SAR peaks in the third period (37.5 cases/100 contacts), resurging in the last period (21.4 cases/100 contacts). HOCI's SAR remains high, specially in shared rooms. Transmission becomes faster, as new variants spread (e.g. omicron). Vaccination impact on transmission is low-moderated in COVID, as in other respiratory infections (e.g. influenza). Thus, surveillance in vulnerable hospital population remains key for rapid identification, early treatment, prevention of new cases and avoiding services collapse in high incidence periods, as winter.

Job strain during covid-19 in private healthcare facilities sousse: prevalence and associated factors (tunisia)

Waad Belgacem¹, Sihem Fredj², Nawel Zammit², Rim Ghammam², Amani Maatouk¹, Sirine Ghribi¹, Jihene Maatoug², Hassen Ghanem², Imed Harrabi²

¹Farhat Hached Hospital, Epidemiology Department, "LR19SP03", 4000, Sousse, Tunisia Tunisia, ² Farhat Hached Hospital, Epidemiology Department, "LR19SP03", 4000, Sousse, Tunisia 2. University of Sousse, Faculty of Medicine of Sousse, 4000, Sousse, Tunisia

Background: According to the WHO, COVID-19 pandemic has had a negative impact on the health, well-being of people worldwide. Healthcare workers (HCWs) represent a particularly vulnerable group due to increasing work stress. Our study aimed to describe the prevalence of job strain among healthcare workers (HCWs) in private clinics in Sousse and evaluate the association between job strain and mental health

Methods: A cross-sectional study conducted among HCWs working in private clinics Sousse, from September 2020 to November 2020. The calculated sample size was 454 employees. In collaboration with the Group of Occupational Medicine of Sousse (GOMS), convenience sampling was conducted to include 5 private clinics and GOMS. Hospital Anxiety and Depression Scale (HADS) used to assess anxiety and depression disorder and the KARASEK model to assess work-related stress. We used SPSS 20 software for statistical analysis.

Results: A total of 543 participants with a female predominance (68.3%) and a sex ratio of 0.36. The mean age was 34.15±8.73 years. The prevalence of job strain was 17.5% ($n=95$). It was higher in women (19.1%) than men and in employees between 25-35 years (18.4%). Also, employees who had certain anxiety according to the HADS scale were more predisposed to have a Job-Strain (25.9%) than those with doubtful or no anxiety ($p=0.002$). The same for employees suffering

from certain depression were more likely to have a job strain with a percentage (24%) than those with doubtful or no depression ($p=0.007$). Being a laborer was significantly associated to having a job strain (24,2%) than the others job positions ($p=0.035$). Conclusion: HCWs are at the forefront of combating any emerging diseases, which increases the risk of job strain and mental health problems. Studying our COVID-19 experience can help us be more prepared in case of another health emergency or pandemic.

Surveillance of sars-cov-2 load and types in open sewage streams within slum districts of medellin-columbia, caracas-venezuela, kampala-uganda, and suva-fiji: a multidisciplinary approach to inform public health on pathogen spread in low resource settings

Eric Arts¹, Justin Donovan¹, Adebawale Abebiyi¹, Jessica Pardy¹, Amanda Hamilton¹, Christopher DeGroot¹, Richard Gibson¹, Quinones-Mateu Miguel², Michael Siemon¹, Hector Rangel³, Wildeman Zapata⁴, Brian Lubega⁵

¹Western University Canada, ²University of Otago New Zealand, ³Instituto Venezolano de Investigaciones Cientificas Venezuela, ⁴Universidad Cooperativa de Colombia Colombia, ⁵Joint Clinical Research Centre Uganda

Background and objective: Surveillance of SARS-CoV-2 during the pandemic has shifted from individual PCR testing to population-based surveillance using wastewater (WW). Our ongoing WW surveillance of SARS-CoV-2 load/types has been effective in Ontario, Canada and Otago, New Zealand, a catchment of ~13 million people. With minimal sewage processing in low-income, densely populated regions (slums), WW collection should involve sampling open sewage streams for optimal pathogen surveillance and for future targeted public health initiatives.

Methods: During June-August of 2021 and 2022, over 1000 samples were collected from streams in slum areas of Medellin-Columbia, Caracas-Venezuela, Kampala-Uganda, and Suva-Fiji. Extracted RNA, converted to cDNA was subject to qRT-PCR and ARTIC v4 Illumina sequencing to measure SARS-CoV-2 load and type. Chemical composition of WW, sample clarity, rainfall, and GPS coordinates for all collection sites were recorded.

Results: Over 40% of stream samples were positive by qRT-PCR for SARS-CoV-2 with the Delta variant dominating in summer 2021. Rainfall diluted viral levels even when standardizing with Pepper mild mottle virus, a "human" excrement standard. Populations in these slums were estimated based on roof density from satellite imagery using GISArcPro. Expected SARS-CoV-2 case loads from WW virus levels were modeled from WW and case load monitoring for SARS-CoV-2 cases in Ontario, Canada during the Delta wave. Based on these models, case loads predicted from WW in the slums of Caracas and Kampala were at least 100x higher than the total cases reported for the entire country of Venezuela and Uganda during the Delta wave.

Conclusions: During the pandemic, SARS-CoV-2 case loads have been under reported in low-income settings. Improve pathogen surveillance directly impacting public health response is feasible through WW but for low income countries, proper sampling and procedures are critical.

DOI: 10.18332/popmed/164620

Efficacy of COVID-19 vaccination campaign in elderly people residing in long-term care facilities: a retrospective observational study from Lombardy region, Italy

Riccardo Vecchio¹, Roberta Lattanzio², Chiara Marrocu³, Sudwaric Sharma³, Giovanni Cicconi², Sara Piccinelli³, Gaia Ferraguzzi³, Anna Odone³, Catia Borriello⁴, Danilo Cereda⁴

¹Università di Pavia via Santa Maria delle Selve, 9 Biassono (MB) 20853 Italy, ²Università di Milano, ³Università di Milano Italy, ⁴Directorate General for Health, Lombardy Region Italy

Background and objective: Prevention Unit from GD Welfare Lombardy evaluated COVID vaccination efficacy among elderly patients who reside in Lombardy long-term care facilities. Aim of the study was to observe the trend of COVID infections and related hospitalizations and deaths in the trimester September-November 2022, in relation to the number of anti-COVID vaccination shots received.

Methods: Population included 55,478 patients. Data were extracted from regional disease reporting application "tableau server". Based on number of inoculations received, patients were stratified and four categories were identified: unvaccinated, vaccinated with less than three doses (patients who did not complete the primary cycle were excluded), vaccinated who received a third dose (1st booster shot), vaccinated who received a fourth dose (2nd booster shot). Only mRNA-based vaccines were employed. For each category, different outcomes were assessed: infection rate, hospitalization rate, mortality rate.

Results: 138 out of 521 unvaccinated became infected (26,5%); infection rate in vaccinated resulted 7,3% for patients with primary cycle completed (120/1643), 11,1% for vaccinated with 1st booster shot (1085/9718) and 11,4% among patients who received a 2nd booster dose (4970/43422). Overall infection rate was significantly higher in unvaccinated (26,5%) than vaccinated (0,11%) cohort. Among unvaccinated patients, 6 were hospitalized (1,2%) and 15 died (2,9%). Hospitalization rate in vaccinated was 0,3%, mortality rate 0,5%: in patients with primary cycle completed, 5 hospitalizations (0,3%) and 8 deaths (0,5%) were counted. Hospitalization rate was 0,4% and 0,2%, respectively, in 1st boost (n=35) and 2nd boost cohorts (n=108). Furthermore, mortality rate resulted 0,1% among vaccinated with 1st booster shot (n=67) and slightly increased to 0,4% among 2nd booster group (n=198).

Conclusion: Infection, hospitalization and mortality rates significantly decrease as patients complete at least the primary vaccination cycle. Data confirm the importance of COVID-19 vaccination campaign as prevention tool in elderly patients residing in long-term care facilities.

DOI: 10.18332/popmed/164627

Socio-economic deprivation and sars-cov-2 related mortality: A retrospective observational study in the pre-vaccinal era.

Fabrizio Cedrone¹, Emilio Greco², Livio Duca¹, Federica Carfagnini¹, Valterio Fortunato¹, Giuseppe Di Martino¹

¹Local Health Authority of Pescara, Abruzzo Italy, ²Research Department Link Campus University, Rome Vincenzo Montagna Università Politecnica delle Marche, Ancona Italy

Background Social determinants of health heavily impact population outcomes. The association between the impact of covid-19 pandemic and health inequalities have been identified in several countries. Comorbidities such as diabetes, cardiovascular diseases and obesity are more prevalent among people from deprived areas. This study aimed to evaluate the association between socio-economic status, based on a Deprivation Index, and the covid-19 related mortality in a Region of Southern Italy in the pre-vaccination pandemic era. **Methods** A retrospective observational study was conducted considering all SARS-CoV-2 positive patients from Abruzzo Region, Southern Italy, from February 24th, 2020 to January 15th, 2021. Data such as demographic information, comorbidities, hospitalizations and mortality, was obtained during contact-tracing procedures. The Italian socioeconomic deprivation index (DI), divided in quintiles (from 1st less deprived to the 5th most deprived) was attributed to all patient, based on the municipality of residence. A multivariable logistic regression models was performed to evaluate the association between death, as a dependent variable, and DI, dividing the study population in two samples, hospitalized patients and non-hospitalized patients. **Results** In the study period, 67,489 SARS-Cov-2 positive were considered, of which 2,746 (4.06%) were hospitalized. The prevalence of deaths among those who have been hospitalized is 4.66%, for all others 0.18%. Among hospitalized patients, no association between death and DI was shown. Among patients died outside the hospital, there is a positive association with the fourth (aOR 2.58;95%CI 1.34-4.94) and fifth quintile (aOR 2.39;95%CI 1.21-4.17) of the DI. **Conclusions** The socioeconomic deprivation is associated with mortality in non-hospitalized SARS-CoV-2 patients and not among hospitalized patients. The care of patient out of the hospital represents an important challenge and these evidences can be of help the policy maker in order to promote preventive measures to address inequalities.

DOI: 10.18332/popmed/164341

From alpha to omicron: how variants shaped sars-cov-2 school transmission

Javier Perez-Saez¹, Mathilde Bellon¹, Andrew Azman Johns², Julie Berthelot¹, Emma Hodcroft³, Maria-Eugenia Zaballa¹, Hélène Baysson¹, Francesco Pennacchio¹, Julien Geneva¹, Arnaud L'Huillier¹, Klara Posfay-Barbe¹, Sebastian Maerckel⁴, Idris Gessous¹, Isabella Eckerle¹, Silvia Stringhini¹, Elsa Lorthe¹

¹Geneva University Hospitals Switzerland, ²Hopkins Bloomberg School of Public Health United States, ³University of Bern Grégoire Michielin Ecole Polytechnique Federale de Lausanne Switzerland, ⁴Ecole Polytechnique Federale de Lausanne Switzerland

Background and objective: SARS-CoV-2 transmission among young children in schools is of major importance due to their potential role in fueling community-wide transmission. Initial studies found little within-school transmission, with few reports after more infectious variants emerged. We aimed to determine how variants of concern (VOCs) altered within-school transmission dynamics among

young children.

Methods: We implemented a prospective observational surveillance study in 3 pre-school and 2 primary schools in the canton of Geneva, Switzerland. We sampled children between 2 and 6 years of age, educational staff, and household members. We collected oral-swab PCR tests, capillary blood for anti-spike serology and questionnaires for household and class members at the time of outbreak declaration and at two subsequent time points (day+2 and day+30). All available virological samples underwent whole genome sequencing. We developed a mathematical model of SARS-CoV-2 transmission to infer time-varying force of infection within schools and from the community at large.

Results: Between March 2021 and June 2022, we recruited a total of 351 children and 107 staff, and 111 of their household members. We investigated eleven SARS-CoV-2 outbreaks (two Alpha, six Delta and three Omicron), involving a total of 33 classes. Phylogenetic analysis on 56 available sequences from seven of the outbreaks (one Alpha, three Delta and three Omicron) indicate that clustering differed between variants, with a higher degree within-school clustering for the Alpha outbreak and lower for the Omicron outbreaks. Modeling results integrating epidemiological and genetic data supported a changing importance of within-school vs. community transmission as more infectious variants emerged.

Conclusion: The importance of within-school SARS-CoV-2 transmission changed with the emergence of more infectious variants. The potential impact of interventions in educational settings depends on these changes and could be tailored to specific transmission scenarios.

Impacts of the Oswaldo Cruz foundation plan to combat covid 19 in the favelas of Rio de Janeiro: Community participation and inter-institutional work in response to the pandemic

Richarlls Martins¹

¹Fiocruz Brazil

Background and objective: The Oswaldo Cruz Foundation (Fiocruz) Plan to Combat COVID19 in the Favelas of Rio de Janeiro (PFECFRJ) is an inter-institutional action coordinated by Fiocruz, in partnership with the Brazilian Association of Collective Health, Brazilian Society of Progress for Science, universities and civil society, which acts directly to mitigate the multidimensional effects of COVID19 pandemic in favelas. With a budget of USD 4 million dollars, PFECFRJ supported 54 projects with a focus on comprehensive territorial-based health actions aimed at reducing COVID19. The main objective of this work is to analyze the results of the implementation of this public health policy between 2020-2022 and point recommendations for health actions aimed at socially vulnerable populations in contexts of health emergencies.

Methods: The research methodology has as its object the analysis of the genesis, formulation and implementation of the PFECFRJ, based on thematic axes: political actors; political process; agenda setting; policy formulation; and policy implementation. The theoretical approach focuses on Kingdon's multiple flows model (Kingdon, 2003). The research used data from the monthly and final reports of the 54 projects supported by the PFECFRJ as a source and carried out 70 semi-structured interviews with actors who acted in the set of these health actions.

Results: The study shows the direct impact of the actions carried out on indicators associated with the reduction of food insecurity in the analyzed territories, the expansion of territorial-based health surveillance actions and the expansion of community communication in health with a focus on the prevention of COVID19. **Conclusion:** The research points out that the partnership between academia, public health management and civil society has a greater potential for incidence in territories in contexts of greater social vulnerability in the response to COVID19 when community participation is a structural element of the organization of the health network.

Buffer spaces in healthcare facilities: strategies for managing and designing strategic areas

Marco Gola¹, Daniele La Milia², Chiara Cadceddu², Chiara Cadceddu², Francesco Altems², Barbara Altems², Raffaella Altems², Marcello Altems², Cristina Altems², Albino Altems², Giuseppe Altems², Alexander Johnson³, Gianfranco Damiani², Carlo Altems², Maddalena Buffoli¹, Andrea Rebecchi¹, Stefano Capolongo¹, Walter Ricciardi²

¹Design & Health Lab, Politecnico di Milano Italy, ²Università Cattolica del Sacro Cuore Italy, ³Columbia University United States

Introduction: The recent covid-19 experience highlighted the difficulty of healthcare facilities in responding promptly to emergencies. hospitals had to reorganize their

spaces, suspending the ordinary medical activities for ensuring the emergency management of the patients' surplus.

A working group of the postgraduate training course in healthcare management by Attems School in Rome conducted a survey on the buffer space (bs), which could support, in case of emergency, the hospitals.

Methodology: The team elaborated a double questionnaire to be administered respectively to healthcare staff and designers with a series of questions aimed at understanding the features of bss. the questions were divided into general information, activities carried out during the pandemic and specific questions on the features of bss. many questions were the same for the two types of participants, while some differed in relation to the respective organizational and design skills of the users.

Results: 102 healthcare professionals and 56 designers took part to the survey. the data analysis permitted to highlight a series of specific inputs that the bs project should take in consideration, such as: a) proximity to the emergency department (ed), intensive care (icu) and inpatient wards (iws); b) location within the hospital but separate from other medical areas; c) independent access; d) organizational and spatial features similar to ed, icu and iws; e) configuration of an operational space ready for whatever type of need; f) the bs should host approximately 12% of the ed stations (40 sqm/per station).

Conclusions: The research aims to become a starting milestone for future investigations: in fact it is necessary to carry out a widespread analysis at the international level.

Although the research was focused in hospital settings, the covid-19 pandemic referred also to the territorial healthcare facilities and therefore some considerations on that issue need to be improved.

Mental health during the covid-19 pandemic, a population-based observational study of antidepressant dispensing

Julie Arnott¹, Paul Corcoran², Ivan Perry¹

¹University College Cork School of Public Health Western Road Western Gateway Building Ireland, ²University College Cork

Background: In Ireland, national surveys have been conducted to measure the impact of COVID-19 pandemic on well-being, however national statistics on mental distress are lacking. This study aimed to investigate the effect of the pandemic by analysing a key indicator of mental distress, antidepressant prescribing.

Methods: Population-based observational study over 7 years analysing two national datasets of anonymised aggregate dispensing data of WHO ATC classification N06A (antidepressants). The Health Market Research Ireland Ltd. (HMR) dataset is based on national retail pharmacy sales for both private and public patients; and the General Medical Services (GMS) dataset is based on publicly-funded prescriptions (approx. 31% of population eligible). Non-GMS figures are derived from the HMR and GMS datasets. Gender and agegroup data only available for GMS dataset. Descriptive statistics, and poisson regression were performed using STATA 15. Incidence Rate Ratios (IRR) with a p-value of <0.05 were considered statistically significant.

Results: Annual trends found statistically significant changes in the prescribing of antidepressants. Rates increased year on year in both datasets. In the HMR dataset increased prescribing was accelerated by the pandemic; a rate of prescribing in 2020 was 1.07 times higher than 2019 (IRR: 1.03), increasing further in 2021 (IRR: 1.09). However, in the GMS dataset, the rates decelerated from an IRR of 1.05 in 2019 to 1.04 in 2020 and 1.01 in 2021. By deducting the GMS figures from the HMR figures 'non-GMS' prescriptions increased from 1.02 in 2019 to 1.09 in 2020 to 1.16 in 2021.

Conclusion: This study validates national well-being studies with findings that mental distress increased over time during the pandemic. A novel finding is the different impact on two study populations. In the publicly funded GMS dataset, females accounted for two thirds of prescriptions, and the pandemic impacted the mental health of younger age groups greatest, particularly young females.

Brazilian northeast's responses to the covid-19 pandemic: what was missed to end the epidemic?

Ligia Sansigolo Kerr¹, Carl Kendall²

¹Universidade Federal Do Ceara Professor Rua Cumbuco, 94 Residencial Alphaville Fortaleza Brazil, ²Tulane University Federal University of Ceará Brazil

Background: Brazil's response to the COVID-19 pandemic was one of the worst in the world. However, governors and mayors of the northeast region of the country,

among the poorest states in Brazil, joined to organize their technical, economic and political responses to the pandemic to reduce hospitalizations, deaths and the economic impact of the pandemic. However, as the pandemic continued, the response became less effective and appropriate. The aim of this study is to document and review this history and the reasons for the growing ineffectiveness of the planning and the interventions.

Methods: A timeline of intervention events was established for the nine states.

Surveillance data was added to the timeline. A desk review was conducted reviewing published and unpublished accounts of policies and programs as well as pandemic major news and political events that captured public attention.

The narrative constructed was then shared with expert public health specialists in the nine states to guarantee accurateness.

Results: In the first wave of the pandemic, most governors in northeastern Brazil responded actively to mitigate the impact of the pandemic. Physical distancing was promoted, including some lockdowns, the use of masks was made mandatory throughout 2020 and part of 2021, vaccination was carried out as doses were received from the federal government, the number of ICU beds was increased, economic measures were instituted to alleviate the situation of families that were left without permanent or temporary employment. However, over time as economic pressure increased and despite the entry of several more transmissible variants, masks were withdrawn, emphasis on immunization was reduced, communication with the population regarding the increase in cases declined, as well as the need to return to masks, complementing doses or boosters of the vaccine and the impact of repeated reinfections on the body, even among those with frank disease.

Risk factors associated with in-hospital death of COVID-19 patients in Khouribga province-Morocco, March, 13, 2020- March, 13, 2021

Said Zaria¹

¹FETP- MOROCCO, Khouribga, Morocco

The spread of the new coronavirus SARS-CoV-2, discovered in China in January 2020, led to a pandemic as early as March 2020. On March 13, 2021, the number of Morocco confirmed cases reached 488 632, and 8 718 deaths were recorded. The province of Khouribga recorded its first case on March 13, 2020. It was a Moroccan residing abroad (Italy). Until March 13, 2021, had 4239 confirmed cases, of whom 4086 were cured and 153 cases of death by COVID-19 including 115 cases at the hospital level. This study aimed to identify the risk factors associated with mortality of patients hospitalized with COVID-19, in Khouribga provincial hospital. This was a case-control study conducted from March 13, 2020 to March 13, 2021. The research involved 339 Patients residing in the province of Khouribga, 113 deceased COVID-19 patients and 226 discharged patients were included as the case group and control group, respectively. Sociodemographic, epidemiological, clinical, biological, radiological, therapeutic and comorbidity variables on admission were collected from medical records. The risk factors were determined by bivariate and multivariate analyzes. The Backward Stepwise Regression demonstrated that age of 62+ years (OR = 3,10 ; IC 95% : [1,34-7,17]), patients reported having two or more comorbidities (OR = 5,94 ; IC 95% : [2,05-17,23]), Diabetes (OR = 3,23 ; IC 95% : [1,16-8,98]), lymphopenia $<1.2 \times 10^3 / \text{mm}^3$ (OR = 2,45 ; IC 95% : [1,09-5,46]), Oxygen saturation $<89\%$ (OR = 8,86 ; IC 95% : [3,60-21,78]), and Time between onset of clinical signs and admission to hospital > 7 days (OR = 3,30 ; IC 95% : [1,44-7,53]) were independent risk factors of mortality of COVID-19 patients. The risk factors identified may help to determine patients at high risk of death at an early stage and guide the optimal treatment.

Protection of Omicron BA.5 from previous Omicron BA.1/BA.2 infection- and vaccine-induced immunity

Shohei Yamamoto¹

¹Department of Epidemiology and Prevention, National Center for Global Health and Medicine, Tokyo, Japan

Background and Objective: The role of previous SARS-CoV-2 infection/vaccine-induced humoral immunity against protection of Omicron BA.5 infection is unknown. We examined the association between pre-infection anti-SARS-CoV-2 spike antibody titers and the effectiveness against Omicron BA.5 infection among staff of a medical and research center in Tokyo.

Methods: A total of 2610 staff participated in a serosurvey in June 2022 (baseline), were measured with anti-SARS-CoV-2 antibodies (spike and nucleocapsid [N] proteins; Abbott and Roche), and answered a questionnaire. Previous SARS-CoV-2 infection was defined according to a history of COVID-19 and anti-N seropositivity

at baseline. Using in-house COVID-19 registry, we followed participants for SARS-CoV-2 infection from baseline to September 21, 2022, during the Omicron BA.5 epidemic in Japan. We used a Cox proportional hazard model to estimate the hazard ratio of Omicron BA.5 infection; and calculated effectiveness as $(1 - \text{hazard ratio}) \times 100$.

Results: At baseline, 92% have completed 3-dose vaccinations, whereas 16% had previous SARS-CoV-2 infection (mainly occurred during Omicron BA.1/BA.2 waves). Those with previous infection had higher anti-spike antibody titers than infection-naïve (median titer: 29,201 v.s. 4,849). After adjusting confounders, higher anti-spike antibody titers were associated with higher effectiveness (3.7% per 1000 titer [95% CI: 3.3–4.2]). The association appears stronger among those previously infected; 50% effectiveness was achieved at 20,000 and 28,000 AU/ml among those previously infected and infection-naïve participants, respectively, and 80% effectiveness was achieved only among the former at 54,000 AU/ml.

Conclusions: Among vaccine recipients (mainly 3-dose) who had experienced Omicron BA.1/BA.2 wave, we found that higher anti-spike antibody titers were associated with a lower risk of Omicron BA.5 infection, and the association was enhanced by previous infection. These data suggest that pre-infection spike antibody titers inform the risk of Omicron BA.5 infection and that high effectiveness can only be achieved with hybrid immunity from infection and 3-dose vaccination.

The role of biomarkers in diagnosis of COVID-19: a systematic review

Raveena Khasla¹

¹St George's University of London, United Kingdom

Background: COVID-19 impacted healthcare worldwide. Biomarkers are a critical tool in monitoring health and guiding treatment to the novel strain. Aim: To assess whether biomarkers can successfully predict clinical outcomes and associate with the severity of the disease. Methods: A systematic review of the literature was carried out to identify relevant articles using six different databases. Keywords to refine the search included COVID-19, SARS-CoV2, Biomarkers, among others. Only studies which reported data on pre-defined outcomes were included. Key Findings: Thirty-four relevant articles were identified which reviewed the following biomarkers: C-reactive protein, serum amyloid A, interleukin-6, lactate dehydrogenase, neutrophil-to-lymphocyte ratio, D-dimer, cardiac troponin, renal biomarkers, lymphocytes and platelet count. Of these, all but two, showed significantly higher levels in patients with severe complications of COVID-19 infection compared to their non-severe counterparts. Lymphocytes and platelet count showed significantly lower levels in severe patients compared to non-severe patients. Conclusions: Although research is still in its early stages, the discovery of how different biomarkers behave during the course of the disease could help clinicians in identifying severe disease earlier and subsequently improve prognosis. Nevertheless, we urge for more research across the globe to corroborate these Findings. Keywords: biomarkers; blood tests; COVID-19; SARS-CoV-2. Links: [1] mailto:m1606869@sgul.ac.uk

Regional differences in population ageing and death rate due to COVID-19 in Bulgaria

Dima Tsanova¹, Eleonora Mineva-Dimitrova², Stela Georgieva³, Mariela Kamburova³

¹Department of Social Medicine and Health Management, Faculty of Public Health, Medical University-Pleven, Bulgaria, ²Department of Social Medicine and Health Management, Faculty of Public Health, Medical University of Pleven, Pleven, Bulgaria, ³Department of Social Medicine and Health Management, Faculty of Public Health, Medical University-Pleven, Pleven, Bulgaria

Background: Bulgaria is one of the countries with the highest level of ageing using the share of people over 65 years of age /22% for 2022/ - on the eighth position in the world ranking. The population ageing in Bulgaria is one of the most significant demographic problems nowadays. The level of ageing in different regions of Bulgaria has varied values. This report Aims to investigate and conduct a comparative analysis of indicators of the death rate due to COVID-19 and population ageing in 2021 in Bulgaria.

Methods: The regional indicators for ageing and mortality due to COVID-19 were analysed based on the National Statistical Institute data. The absolute numbers were regrouped and the main indicators for population ageing were calculated. Analysis and calculations were performed by MS Excel 2019. Data have been

statistically processed with SPSS v.24. To establish the relationship between death rates and ageing, Pearson's correlation coefficient has been used. Results: The study found that the death rate due to COVID-19 in Bulgaria for 2021 is 401.12 per 100000 population but there are six regions where the level of the indicator is above 500 – Silistra, Vratsa, Gabrovo, Montana, Vidin, and Kyustendil. Kyustendil, Gabrovo, and Vidin are the regions with the highest level of ageing in our country - respectively 27.77%, 29.11%, and 29.69%, the level for the country is 21.67%. The statistical analysis shows that there is a positive correlation between ageing and death rate due to COVID – 19, The Pearson coefficient is 0.503. Conclusions: The regional health inequalities in Bulgaria are very important in order to control and decrease the level of mortality in the country especially the death rate due to COVID-19.

Associated factors with acceptability of vaccination against COVID 19 among health workers in Koumpentoum Health District (Senegal)

El Diop¹

¹District Sanitaire de Koumpentoum, Senegal

Background and objectives: Vaccination of health providers is one of the priorities in the response to COVID 19. During this pandemic, the relaxation of vaccine licensing procedures has led to scepticism and mistrust among health care providers and the emergence of rumors that are harmful to COVID 19 vaccination, particularly through social networks. The Objective of this study was to identify factors associated with the uptake of the second dose of Sinopharm by health workers in Koumpentoum health district.

Methodology: This was a cross-sectional, descriptive and analytical survey. We conducted a descriptive and analytical study that explored the knowledge, attitudes and practices and acceptability of COVID 19 vaccination by health workers in Koumpentoum health district. Multiple logistic regression was used to identify factors associated with taking the second Sinopharm dose.

Results: In total, we had (168) respondents of whom (59.95%) were women. The mean age was (37.05 ±9.76) years and the median (35) years. Almost all of them, (85.71%), were living with a partner. Unskilled workers represented (74.4%) of respondents. The average length of professional experience was (8.51 ± 5.81) years with median of (7) years. Frequency of co-morbidities was (8.93%), this of the COVID 19 (10.12%) and this of adverse events (16.67%). The second dose coverage of Sinopharm was (82.74%) and the statically and significantly associated factors were age > (35 years (ORa = 4.51 [1.71-11.91]; p = 0.0023), living with a partner (ORa = 4.11 [1.36-12.45]; p = 0.0123) and work experience > (5) years (ORa = 3.15 [1.01-9.08]; p = 0.0321).

Conclusions: Factors related to vaccination of health workers against COVID 19 in Koumpentoum district are age, marital status and work experience. Awareness raising and vaccination of young health workers should be a prerequisite for the plan to revive and intensify vaccination against COVID 19.

Factors influencing the practice for COVID-19 prevention among health personnel in Tertiary Hospital, Bangkok Thailand

Kampong Kamnon¹

¹Rajavithi Hospital, Bangkok, Thailand

Background and Objective: COVID-19 infection among health personnel is a major problem and has severe impacts. This cross-sectional survey design aimed at the factors influencing the practice of COVID-19 prevention among health personnel.

Methods: The sample consisted of health personnel working in the emergency department, in-patient wards, and out-patient department in Rajavithi hospitals (n=60) selected using a purposive sampling method. Data were collected using questionnaires which were validated by 5 experts and had a content validity index of 0.83. The reliability of the questionnaires was 0.91. Data were analyzed using descriptive statistics and multiple regression.

Results: The results of this study revealed that subjects had good attitudes toward behaviors, subjective norms, perceived behavioral control, and intention for COVID-19 infection prevention. In addition, perceived behavioral control was the only factor that statistically predicted practice intention for COVID-19 infection prevention and may explain 25.6% of the variability of intention (p < .001).

Conclusions: Based on the Results of this study, it is suggested that relevant authorities including wards and infection control units should support perceived behavioral control among registered nurses to encourage COVID-19 infection prevention intention for COVID-19 infection prevention.

Effect of the COVID-19 pandemic on diet among university students in France

Marie-Pierre Tavolacci¹, Joel Ladner², Lise Miller³

¹Clinical Investigation Centre CIC 1404, INSERM and CHU Rouen, France,

²Chu Rouen INSERM, France, ³Department of Health Promotion, CHU de Rouen, France

Introduction: The COVID-19 pandemic and the lockdowns have affected many aspects of university students' daily lives, including their dietary habits. This study aimed to evaluate the change of diet quality of university students before and during the COVID-19 period, and the factors associated with unfavorable changes in diet quality. **Methods:** An online cross-sectional study was performed in May 2021 among Rouen (France) university students. Socio-demographic characteristics, body mass index, depression (CESD-8), academic stress, risk of eating disorders (SCOFF test) and food security (FSSM) were collected. The French "Programme National Nutrition Santé- Guidelines Score 2" (PNNS-GS2) was used to access diet quality.

Results: A total of 3508 students were included, 74.4% were female, the mean age was 20.7 (SD = 2.3). Mild and food insecurity concerned 11.3% and 7.0% of the university students, respectively. The risk of eating disorder was detected among 46.6% of the university students. The PNNS-GS2 score decreased between the pre- and the COVID-19 pandemic period for 33.1% of university students. After logistic regression, the associated factors with the decrease in the PNNS-GS2 score were food insecurity, financial insecurity, not living with parents, depression, academic stress, eating disorders, being in the two first years of study and having been infected by COVID-19. **Conclusions:** Diets with healthy components decreased for one-third of university students since the COVID-19 pandemic, and this was shown to be associated with food insecurity, poor mental health and eating disorder. This study provides important information to help public health authorities and universities give better support to student health feeding programs during pandemics and lockdowns. Further research could help develop innovative prevention programs that would seek to promote healthy food and mental health at all times among university students.

Impact of restrictive preventive measures during the COVID 19 pandemic on mortality in Bulgaria

Penka Kostadinova¹, Sergey Kostadinov², Irena Stoilova³, Stefan Kostadinov⁴

¹Department of Social Medicine and Health Management, Plevan Medical

University, Plevan, Bulgaria, ²Department of General Medicine, Forensic

Medicine and Deontology, Faculty of Public Health, Plevan Medical

University, Bulgaria, ³Department of Hygiene, Medical Ecology and

Occupational Diseases, Faculty of Public Health, Medical University, Plevan,

Bulgaria, ⁴Neurosurgery Clinic, General Hospital for Active Treatment Heart and Brain, Plevan, Bulgaria

Introduction: Compared to other countries in Europe, Bulgaria is in first place in terms of total mortality and occupies leading positions both in terms of mortality from COVID 19 and other socially significant diseases. During the pandemic, prohibitions were repeatedly introduced to conduct general preventive examinations and examinations for periodic monitoring of the condition of persons with chronic diseases. In addition, people limited visits to their GP due to fear of contagion. The purpose of the present study is to determine the impact of the introduced restrictive measures for prevention among the population during the COVID 19 pandemic on mortality among the population in Bulgaria. **Materials and methods:** Official data for the period 2018-2021 from the National Statistical Institute in Bulgaria were used, which were processed with statistical Methods.

Results: Total mortality increased significantly during the pandemic (compared to 2019, an increase of 28.5% in 2020 and 39.8% in 2021). One of the reasons is the death rate from COVID 19, which in Bulgaria is higher than the average values for European countries. A significant increase in deaths from diseases of the respiratory system and diseases of the circulatory system was found. The growth in mortality from malignant neoplasms, diseases of the endocrine system and mental illnesses is also impressive. During the pandemic, a lower coverage of the population with preventive examinations is reported (below 35%).

Conclusions: The pandemic of COVID 19 and its consequences gave a reflection, besides a direct cause of death among the population, and as an indirect cause of death in persons mostly with chronic diseases. Restrictions on prevention and early detection of diseases, as well as irregular monitoring of chronically ill people is an additional reason for the increased mortality from socially significant diseases.

Attitude of personnel's of Estonian nursing homes towards vaccination against COVID-19

Ülle Parm¹

¹Tartu Health Care College, Estonia

Background and Objectives: Since the beginning of COVID-19 pandemic, many studies have been conducted to assess public attitudes and readiness for vaccination against COVID-19. Less attention has been paid to nursing home workers, though they have important role in achieving immunity in a vulnerable population. The aim was to clarify the readiness of Estonian nursing home workers to be vaccinated against COVID-19 and the factors influencing their opinion.

Methods: Web-based electronic questionnaire was fulfilled online by nursing home personnel in May 2021. Descriptive statistics, t- or Mann-Whitney, and χ^2 - or Fisher Exact tests were used. In order to measure attitudes Likert-scale (5 degrees), and to identify risk factors associated with decision to vaccinate univariate logistic regression analyses were used.

Results: 139 nursing home workers (caregivers, nurses, cleaners, board members and other specialists) participated. They were divided into pro-vaccination (87.8%); the skeptics (3.6%); anti-vaccination (8.6%) groups. Pro-vaccinators wanted to protect themselves (73.8%). Anti-vaccinators believed that there is not enough information about vaccines (75%) and vaccination is not necessary (33.3%) or even dangerous (41.7%). Vaccination was influenced by married/long-term relationship status and caregiver occupation (OR=3.01, 95% CI 1.04–8.76; OR=0.26, 95% CI 0.09–0.75, respectively). Most participants agreed that vaccination is important because it prevents severe illness (84.2%), protects others (82.7%) and limits the spread of disease (81.3%). The belonging to vaccination group was positively influenced by family status (cohabitation or marriage) (OR=3.01, 95% CI 1.04–8.76) but negatively by belonging to caregiver group (OR=0.26, 95% CI 0.09–0.75).

Conclusions: Employees of Estonian nursing homes are mostly in favor of receiving COVID-19 vaccine. There were also skeptics and opponents of vaccination, which could have a negative impact on the health behavior and health of nursing home residents. Vaccine skepticism is a global problem and thus awareness and vaccination campaigns must continue.

DOI: 10.18332/popmed/164986

Attitude of the Estonian-speaking population towards the COVID-19 vaccination

Anna-Liisa Tamm¹

¹Tartu Health Care College, Estonia

Background and Objectives: Vaccination is a simple, safe and effective way to protect from harmful diseases, but unfortunately, vaccine resistance is on the rise worldwide. The aim of study was to clarify the attitude of Estonian-speaking population towards COVID-19 vaccination and main reasons for accepting or refusing vaccination.

Methods: The online electronic questionnaire was completed online by Estonian-speaking citizens in May 2021. Descriptive statistics, t- or Mann-Whitney, and χ^2 - or Fisher Exact tests were used. In order to measure attitudes Likert-scale (5 degrees), and to identify risk factors associated with decision to vaccinate univariate logistic regression analyses were used.

Results: Participants (n=508; 33.5±12.3y) were divided into: pro-vaccination (78.7%), many of them had already been vaccinated with either one or two doses (36.5%, 31.5%, respectively) or were planning vaccinate soon (32%); the skeptics had not decided (12%); anti-vaccination (9.3%). The main reason why vaccination was preferred was the belief that by vaccinating we help those who for some reason cannot vaccinate themselves (81.7%) and in case of concomitant diseases COVID-19 can be extremely severe (80.9%). 6.5% of anti-vaccinators believed that their body protects itself from the disease, and 4.7% believed that vaccination should not violate the sanctity of the human body. The main reasons for vaccination resistance were insufficient research on vaccines (80.9%) and general attitude towards the necessity of vaccines (48.9%). The belonging to vaccination group was influenced by living in an urban area and student status (OR=1.96, 95% CI 1.28–3.02; OR=2.39, 95% CI 1.26–4.55, respectively). Anti-vaccination status was primarily influenced by a secondary vs higher education (OR=2.34, 95% CI 1.14–4.77, p=0.02). Skeptics and opponents of vaccination mainly believe media (24.6%); vaccinators mostly the opinion of health professionals (16%).

Conclusions: Vaccine skepticism is a global problem and thus awareness and vaccination campaigns must continue.

The impact of the COVID-19 pandemic on the physical activity of the population of adult residents of Lithuania

Rokas Arlauskas¹, Rimantas Stukas², Donatas Austys¹

¹Faculty of Medicine, Vilnius University, Lithuania, ²Vilnius university Faculty of Medicine, Lithuania

Background and objective: The COVID-19 pandemic has introduced changes in physical activity of various populations. The aim of this study was to assess the impact of the COVID-19 pandemic on physical activity in a representative sample of adult residents of Lithuania. **Methods:** The survey data was collected from October to November 2021. After the exclusion of missing data, this study included a representative sample of 1502 adult residents of Lithuania aged from 18 to 64 years old. The chi-square criterion was used to estimate the association between sociodemographic variables, COVID-19 experience and food selection criteria with change in physical activity during the pandemic.

Results: Although the majority (54.7%) of the participants of this study indicated no effect of the COVID-19 pandemic on their physical activity, 33.8% of the sample indicated the decrease in physical activity. During the pandemic, physical activity increased among 11.4% of the respondents. Decrease in physical activity was more frequent among younger respondents (38.6% vs. 29.6%), people from the largest towns of Lithuania (39.9% vs. 29.4%), single respondents (45.7% vs. 31.2%) and those who suffered from COVID-19 personally or had COVID-19 cases in their families (28.6% vs. 41.8%) (p<0.05). Physical activity increased more frequently among respondents with university education and those who selected their foods with respect to its impact on health (respectively, 14.4% vs. 5.8% and 15.6% vs. 9.6%) (p<0.05). Gender, employment status, number of family members, having children under 18 years, monthly income per family member and severeness of COVID-19 of the respondents were not associated with changes in physical activity during the pandemic (p>0.05). **Conclusions:** The COVID-19 pandemic has reduced the physical activity in one third of the population of adult residents of Lithuania. The decrease was observed among both – residents with higher and lower prepandemic physical activity.

Study of the continuity of tuberculosis-related care during the COVID-19 pandemic between march 2020 and February 2021 in Senegal

Mamadou Leye¹

¹Medecine Preventive and Public Health, University Cheikh Anta Diop of Dakar, Dakar, Senegal

Introduction: Tuberculosis is one of the major public health problems. The COVID 19 pandemic has impacted the health system globally and nationally. Faced with this situation, it was deemed necessary to study the continuity of services related to tuberculosis in Senegal during the COVID 19 pandemic period between March 2020 and February 2021.

Methodology: A cross-sectional study for analytical purposes was conducted between March 2020 and February 2021. The study population was represented by all tuberculosis patients seen in consultation between March 2020 and February 2021 and who reside in Senegal. A multistage survey was carried out at the level of each district. Univariate and multivariate analyzes were performed using Epi Info 3.3.2 and R 3.4.4 software.

Results: The average age of respondents was 41.43 years with extremes 13 and 81 years. Possession of a television was significantly associated with the impact of COVID 19 on the continuity of tuberculosis services. Patients sensitized before Senegal recorded its first case (ORaj 0.09 [0.02-0.43]) were less likely to continue their health care compared to those who received it after the first case. The request for follow-up consultation service was significantly associated with the impact of COVID 19 on the continuity of services related to tuberculosis. Patients who were in the attack phase (ORaj 107.69 [5.94-1951.97]) and maintenance phase (ORaj 50.06 [7.32-342.07]) were more likely to continue their health care compared to those who did not know what phase they were in.

Conclusions: The Results of this work suggest to the health authorities to reorganize the health system and to adopt a policy based on the community approach and to the populations to overcome the “fear of COVID 19”. **Keywords:** continuity, services, prevention, Tuberculosis, COVID 19, Senegal

Changes of influenza vaccination coverage rates due to the

expanded free influenza vaccination program before and during the COVID-19 pandemic in Korea

Jun Hwang¹, Soon-Woo Park¹

¹Department of Preventive Medicine, Daegu Catholic University School of Medicine, Republic of Korea

Background and Objectives: As the COVID-19 pandemic prolongs, the threat of twindemic with influenza and COVID-19 remains. Therefore, this study Aims to evaluate the effect of improving the influenza vaccination coverage rates of free vaccination expansion program before and during the COVID-19 pandemic.

Methods: The present study used the 2020~2021 Korea Community Health Survey (KCHS) data from Kyungpook province in Korea, which includes 23 cities/counties. We analyzed annual influenza vaccination rate, and the 2020 KCHS and 2021 KCHS Results meant the influenza vaccination rates for the 2019-2020 season and the 2020-2021 season, respectively, considering the KCHS survey period (mid-August to mid-October) and adult influenza vaccination period (mid-October or later). During the 2020~2021 season, unlike other regions, one city (Andong) of Kyungpook province introduced free vaccination program for all citizens.

Results: The adult influenza vaccination coverage rate of 2020 and 2021 KCHS increased by only 1.8%p (52.9% in 2020, 54.7% in 2021) in Kyungpook, but increased by 9.4%p (55.9% in 2020, 65.3% in 2021) in Andong. As a Results of comparison by age group in 10-year intervals, vaccination coverage rates for those in their 60s and 70s or older, who were not subject to vaccination expansion program, showed no difference or slightly decreased in both regions between the 2020 and 2021 KCHS. However, the vaccination coverage rate increased respectively by 19.0%p, 15.0%p, and 21.6%p for those in their 30s, 40s, and 50s in Andong. On the other hand, in the 20s, the rate of increase was low in both regions. **Conclusions:** The expansion of the free influenza vaccine program was effective in improving the vaccination coverage rate among adults in their 30~50s, excluding those in their 20s. The temporary expansion of free vaccination programs will be efficient in preventing the twindemic between influenza, and COVID-19 or other emerging infectious diseases.

Users' perceptions of medical services in primary health care during the COVID-19 pandemic in Fortaleza, Brazil

Lourrany Costa^{1,2}, Luciano Cavalcanti^{3,4}, Leonardo Rocha⁵, Sarah Oliveira⁵, José Barreira⁵, Fernanda Faria⁵, Letícia Pontes⁵, Ingrid Vasconcelos⁵, João Freitas⁵, Vitor Malheiro⁵, Iana Marques⁵, Gustavo Bezerra⁵, Pedro Aquino⁵, Lara Medeiros⁵, Leonardo Andrade⁵, Tiago Farias⁵

¹School of Medicine, Universidade de Fortaleza, Brazil, ²Universidade Federal do Ceará, Brazil, ³Department of Conservative Dentistry, Periodontics, Faculty of Dentistry, Centre for Biomedical Research and Innovation (CIIB), Brazil, ⁴Centro Universitário Christus, Brazil, ⁵Universidade de Fortaleza, Brazil

Introduction: Due to the COVID-19 pandemic, several countries reorganized their health systems, prioritizing emergency consultations over primary care. **Objective:** To evaluate adult users perceptions of medical care received between April 2020 and July 2021, in public primary health care (PHC) in Fortaleza, Northeast of Brazil. **Methods:** This is a cross-sectional study involving a survey and analysis of medical records (MR). Between August and November 2021, 126 participants were enrolled, invited by convenience, from 3 PHC units. We performed an ordinal logistic regression to verify the factors associated with users perceptions regarding the medical care received.

Results: 107 women (84.9%) and 19 men (15.1%) participated, with a mean age of 39.7 years; 42.9% of participants waited 30 to 60 minutes for appointments; 69% believed the pandemic interfered with that time; 78.6% believed there were not enough doctors to provide proper care. Distancing, masks, and face shields interfered with consultations, according to 16.7% of respondents. 53.2% rated the services received as "very good". EMR data were collected from 58 participants: 49 women and 9 men. The average number of consultations in the period was 4.47. General consultations and nonspecific complaints were the most frequent ICD-10 codes in the MR, followed by respiratory symptoms and suspected or confirmed cases of COVID-19 (11.5%), and prenatal care (9.6%). The average number of times a user received medication was 9.33. Their perceptions of care were influenced by: believing there were enough doctors available to meet appointments; believing that the pandemic interfered with their waiting time; the availability of professionals for counseling; the user's gender; and the times a user received medication ($p = 0.0002$). **Conclusions:** Clinical consultations maintained their quality according to users despite the pandemic overload and changes in health professionals work. It is possible to use these results in future crises to improve assistance.

Suffering and pleasure in health workers on the front lines of COVID-19

Patricia Baptista¹, Cristiane Gallasch², João Silva-Júnior³, Daniela Lourenção⁴

¹School of Nursing, University of Sao Paulo, Brazil, ²Faculty of Nursing of the State of Rio de Janeiro, Brazil, ³Department of Occupational Medicine, University of Sao Paulo, Sao Paulo, Brazil, ⁴School of Nursing, University of Sao Paulo, Sao Paulo, Brazil

Background and objective: The COVID-19 pandemic occurs in a scenario that already reveals great concern for health workers. Added to this, in a context of constant changes and unpredictability, the risk of increased mental suffering is a worldwide finding. The present study aimed to verify indicators of suffering and pleasure in health workers in the pandemic context. **Methods:** Exploratory, analytical, cross-sectional study with a quantitative approach. The sample consisted of 437 health professionals invited electronically, who answered the questionnaire on sociodemographic information, occupational aspects and clinical conditions. Suffering and pleasure at work were considered as outcomes, which were analyzed with multinomial logistic regression regarding the associated independent variables.

Results: Most participants were female (71.0%), nurses (55.6%), mean age of 38.4 years, with an employment relationship (60.9%) and weekly workload of 40 hours or more (75.8%). Regarding suffering, 61.6% of participants were in mental distress, with the average score having critical levels in professional exhaustion and lack of recognition. As for pleasure at work, it is presented at a critical level, with the freedom of expression factor at a critical level. However, despite the difficulties faced in working on the front lines of COVID, health workers still feel some pleasure in their professional activities, especially due to the professional fulfillment of the tasks performed. **Conclusions:** Suffering at work is associated with occupational characteristics and mental exhaustion and lack of recognition among health workers in the COVID-19 setting.

Pre-COVID-19 cognitive social capital trajectories and peri-COVID-19 depression: a prospective cohort study in China, 2014-2020

Yang Han¹, Roger Chung¹

¹The Chinese University of Hong Kong, China

Background: Social capital is dynamic; however, little is known about the association of its dynamics with health resilience in a pandemic. We examined the longitudinal association of pre-COVID-19 cognitive social capital trajectories with peri-COVID-19 depression and the moderating effect of province-level COVID-19 severity on the association in China.

Methods: We employed four-wave adult (≥ 16 years) data (follow-up $n=6,228$) from the biennial China Family Panel Studies between 2014 and 2020 with peri-COVID-19 depression in 2020 measured by the 8-item Center for Epidemiological Studies-Depression Scale. Pre-COVID-19 cognitive social capital from 2014 to 2018 included dichotomized (high/low) generalized trust, trust in neighbors, trust in local government officials, and reciprocity, with each of them categorized into five trajectories: persistently low, decreased, fluctuated, increased, and persistently high. Province-level COVID-19 severity in 2020 was a factor score constructed by the number of COVID-19 cases and deaths in each province. Mixed-effects linear regression was conducted to answer our research question. **Results:** Persistently low generalized trust ($\beta: 0.46$; 95% CI: 0.15, 0.78), persistently low ($\beta: 0.57$; 95% CI: 0.22, 0.92), decreased ($\beta: 0.36$; 95% CI: 0.07, 0.65), and increased ($\beta: 0.40$; 95% CI: 0.12, 0.68) trust in neighbors, and persistently low ($\beta: 0.39$; 95% CI: 0.02, 0.77) and decreased ($\beta: 0.68$; 95% CI: 0.38, 0.97) reciprocity, compared with their persistently high trajectories, were associated with increased peri-COVID-19 depression. Province-level COVID-19 severity did not significantly moderate the association between pre-COVID-19 cognitive social capital trajectories and peri-COVID-19 depression.

Conclusions: Long-term strategies to maintain high cognitive social capital are needed to protect mental health against a pandemic, regardless of the expected severity of the pandemic.

COVID-19 outbreak: challenges reorganizing a university hospital setting and preserving non-deferrable cares in the South Italy

Emma Montella¹

¹Public Health Department, University of Naples Federico II, Napoli, Italy

Background and objective: This study shares the experience of a covid-19 outbreak response in the university hospital of Naples "Federico II", elected as covid-19 regional hub for the mother-child department and the Paediatric Department. **Methods:** It has been composed a hospital task force with different experts which developed a hospital incident management system (HIMS) requiring a general reorganization of the hospital settings, ensuring hospital services both to the covid-19 patients and to those who needed non-deferrable cares. Data were collected from March 9 to May 8, 2020, and the HIMS efficacy was measured by key performance indicators such as number of covid-19 patients hospitalized/recovered/deads; number of patients/day for cancer therapies; number of patients/day for immunological therapies and many others data on SARS-CoV-2 patients were extracted from the platform "sinfonia". This is the increase in department's capacity: 1. intensive care unit: +57%, 2. sub intensive care unit: creation of a new unit dedicated to covid-19 patients, +18 beds, 3. infectious disease department, all the 14 beds. 4. Paediatric Department, regional hub, 18% converted in covid beds, 5. mother-child department, regional hub, 35,7% of converted in covid beds, 6. internal medicine department, 46,6 % of converted in covid beds staff management: training SARS-CoV-2 exposed staff-staff re-allocation phases. 1) permanent staff: already involved in emergency departments, 2) contingency staff: new workers hired to work in covid departments, +27,2%, 3) crisis staff: workers reallocated from ordinary activities, +18,6% result the ordinary healthcare, despite the pandemic period, ensured 100 patients/day for cancer therapies, 50 patients/day for immunological therapies, 20 patients/week for cancer surgery, 20 patients/week for dialysis, 5 kidney transplants, in line with 2019 data. **Conclusions:** HIMS provided an appropriate response to covid-19 and guaranteed the non-deferrable hospital services. Our experience taught us the importance to have an extra-ordinary management plan to respond to future emergency challenges.

Comparative profiles of anti-SARS-CoV-2 IgG in the blood and milk of Brazilian lactating women vaccinated by mRNA and other vaccine platforms

Daniele Marano¹, Yasmin Amaral^{2,3}, Maria Zuma⁴, Fernanda Mazzoli⁵, Zilton Vasconcelos⁵, Marina Vilarim⁵, Fátima Monteiro⁵, Paulo Borges⁵, Maria Moreira⁶

¹Oswaldo Cruz Foundation (Fiocruz), Brazil, ²Fiocruz, Rio de Janeiro, Brazil, ³Universitário Serra dos Órgãos (UNIFESO), Brazil, ⁴Fundação Oswaldo Cruz (Fiocruz), Brazil, ⁵Fiocruz, Brazil, ⁶Fiocruz, Brazil

Background: The presence of SARS-CoV-2-IgG is directly correlated with the degree of vaccine efficacy. Recent studies have shown the presence of this antibody in the blood and milk of breastfeeding mothers vaccinated with mRNA (Pfizer). However, limited information is available in lactating women that received other vaccine platforms used in developing countries, such as the inactivated SARS-CoV-2 vaccine and the non-replicating adenovirus vaccines. **Objective:** To compare the amount anti-SARS-CoV-2 IgG protein in the blood and milk of lactating women vaccinated against SARS-COV-2 based on vaccine platforms used. **Methods:** A cross-sectional study was carried out with 48 Brazilian lactating women, over 18 years old, contacted by the main social networks. The milk and blood collection will be carried out by professionals previously trained in the human milk bank and clinical laboratories. For the detection of SARS-CoV-2-IgG in samples of blood and breast milk, the technicians used the method of direct enzyme immunoassay (ELISA).

Results: From the total number of lactating women evaluated, 48% received the vaccine with mRNA, 29.2% non-replicating adenovirus and 23% inactivated SARS-COV-2. The average of IgG in blood (5.39) was higher than in milk (1.19), but without significant difference when comparing the results obtained using different vaccine platforms. Most lactating women received the second Pfizer booster dose. There was a reduction in the amount of IgG between the first dose and the second booster dose. However, after applying the second booster dose (40), regardless of the vaccine manufacturer, there was an increase in the average levels of IgG in blood (5.50) and in milk (1.25). **Conclusions:** The present study showed that, regardless of the technology used in developing countries, after the second booster dose there was an increase in the levels of IgG in the blood and milk of nursing mothers, reinforcing the importance of completing vaccination schedule.

KenyaRelief.org as an example of organized improvisation during the COVID-19 outbreak

Elizabeth Studley¹, James Johnson²

¹Kenya Relief, United States, ²School of Health Sciences, Central Michigan University, Mount Pleasant, United States

Kenya Relief (KR) is an NGO in Migori, Kenya, founded in 2001. KR's tripart mission comprises a K-8 school (760 children), an orphanage (165 children), and a 9000 square foot medical clinic that hosts 25 medical-surgical teams per year. On March 13, 2020, international travel was halted, preventing 17 teams from serving. KR CEO, Steve James, immediately halted outside visitors from entering the 60-acre compound. By March 16, all but 14 of KR's 142 employees were sent home with full pay. Fourteen employees (managers, dorm parents, chefs, missionaries, security guards, housekeepers) committed to stay on campus one month to care for the orphans. All revenue from the clinic and school halted from government-mandated shutdowns while orphan sponsorship payments plummeted. By March 18, the CEO had collected educational material on COVID-19 from the WHO and CDC; Discussions were had with the Migori County MOH about new rules pertaining to Kenya and the county; and an emergency board meeting was held regarding the budget and creation of COVID policies, with the board committed to weekly meetings until further notice. The CEO raised 60000 USD by mid-April 2020 that covered salaries and expenses for three months. Ten touchless handwashing stations were placed throughout the campus in April 2020. The local MOH agreed to a staged reopening of the medical clinic after a three-week shutdown. During the nine month school shutdown, teachers sent weekly lesson plans with 82% participation. All KR employees were vaccinated by August 2021. Medical teams resumed February 2021 with missionaries providing vaccination proof; surgical patients received PCR tests within three days of surgery. Lastly, the CEO raised funding toward construction of the Kenya Relief Maternal Child Health Center; groundbreaking on the 65-bed hospital was July 12, 2022, to help address Migori County's maternal mortality rate of 673 deaths/100000 live births.

Knowledge, attitudes, and practices in adapting to COVID-19 pandemic conditions: a cross-sectional survey among the Mongolian population (The second phase follow up study)

Sarantuya Altansukh¹

¹National Center for Public Health, Mongolia

Background: In fact, of COVID-19 confirmed cases, Mongolia is in the top five countries in the West Pacific. A lack of practice to prevention from coronavirus infection period presents a need to improve the prevention, response, and risk communications of Mongolians and ensure the adaptability of citizens. Conducting the knowledge, attitudes, and practices towards coronavirus infection will help identify and address the population's information needs and concerns, provide relevant information, and to save lives.

Methods: The study was conducted participants from 3 remote provinces and 2 districts of Ulaanbaatar Capital city. Kazakh ethnic group in Bayan-Ulgii province, which make 3.9 percent of the total population, was selected through targeted sampling Methodology to determine whether cultural and religious factors influence attitudes towards spreading COVID-19. The survey data was collecting using quantitative, and qualitative methods among three specific groups (health specialists, general population, teenagers). Observations were performed on the population's handwashing situation, duration, use of soap, wearing and removing masks, frequency, and social distancing behavior of people.

Results: Positive changes made in the behavior of handwashing frequency (50.5% to 83.2%), wash hand in the correct order (21.4% to 39.1%), use soap regular (26.0% to 53.2%), wash hand duration (16.1% to 33.5%), the frequency of cleaning and disinfecting of home and the use of disinfectants has been increased, the practice of wearing masks in crowded places and outdoors were increased by 6.8 percent.

Conclusions: To divide the target group into children, adolescents, adults and the elderly and implement activities aimed for them. Promote and develop training program and curriculum for all level education institution and create a supportive environment. Continue to provide essential knowledge sharing activities.

Healthcare workers and COVID-19 vaccination: a living systematic review

Mario Poz¹, Alesandra Silva², Luciana Castaneda³, Raphael Chança⁴, Leila Maia³, Inês Frontera⁵, Isabel Craveiro⁵, Ana Olivieira³, Paulo Ferrinho⁵

¹Institute of Social Medicine, University of Rio de Janeiro State, Brazil,

²Cancer National Institute, Health Ministry, Brazil, ³Institute of Social Medicine, University of Rio de Janeiro State, Brazil, ⁴Cancer National Institute, Brazil, ⁵Global Health and Tropical Medicine, Instituto de Higiene e Medicina Tropical, Universidade Nova de Lisboa, Portugal

Background and Objective: The COVID-19 has shaken the scientific community and highlighted the lack of policies to protect and support health care workers (HCWs) in public health emergencies. The discovery of the vaccine was not enough to defeat the pandemic for several reasons, such as antivaccine behavior, deficit of vaccines in several countries and fragile policies for vaccine coverage worldwide. We aimed to identify HCWs' skills and requirements for covering a target population; countries' politics to uptake vaccination; and strategies for improving vaccination team's performance.

Methods: Living systematic review of studies retrieved from PubMed, Embase, Scopus, Lilacs, Web of Science, WHO COVID-19 database, and Google Scholar published between January 2020 and March 2022. The PICO search tool was used for the research questions about requirements, policies and strategies for HCWs and target population vaccination. Risk of bias and Certainty of evidence were assessed by GRADE CERQual tool.

Results: A total of 4556 studies were identified in the databases. First, 193 studies were selected for retrieval. Then, 162 studies were selected for full-text reading. We identified 29 publications that met the inclusion criteria. After full texts reading, 10 studies were excluded. Data extraction was done from 19 studies. Most of the evidence came from cross-sectional surveys and qualitative studies. The main findings are related to vaccine hesitancy, which is not a minor issue among the HCWs. Countries have embraced few policies for covering the target population and the HCWs worldwide.

Conclusions: The pandemic has yet to be overcome entirely. Skepticism, mistrust, and hesitancy are global issues that can jeopardize immunization coverage. Governments will need guidance to develop and advance policies for vaccine coverage, control outbreaks of new strains. We propose to continue the living systematic review method to accompany the development of strong evidence studies to support public policies on this subject.

Crimes against life, health, sexual violence and accidental death during the COVID-19 pandemic in Bulgaria

Sergey Kostadinov¹, Penka Kostadinova^{2,3}, Stefan Kostadinov⁴

¹Department of General Medicine, Forensic Medicine and Deontology, Faculty of Public Health, Medical University, Pleven, Bulgaria, ²Department of Social Medicine and Health Management, Pleven Medical University, Pleven, Bulgaria, ³Bulgarian Public Health Association, Kostadinova, Bulgaria, ⁴General Hospital "Heart and Brain", Pleven, Bulgaria

Introduction: The COVID 19 pandemic has imposed numerous restrictive measures leading to social isolation. The aim of the current study is to determine the impact of the COVID 19 pandemic and the restrictive measures implemented on crime against bodily integrity and accidental mortality.

Materials and Methods: Official data published by the National Statistical Institute for the period 2019-2021 were used, and the same were processed with statistical methods.

Results: It was found that in 2020 and 2021, total registered crimes against the person decreased compared to the previous two years by an average of about 6%. Compared to those registered in 2019, in 2020 and 2021 the following are reported: murders – 49, a decrease of 12.2% and 10.2%; attempted murders – 26, an increase of 7.7% and 19%; bodily injuries – 825, down 6% and 2.7%; violations against sexual privacy: Debauchery – 98, growth 31.6% and 11.22%; Rape (committed and attempted) – 51, growth 21.7% and no dynamics. Mortality due to accidents decreased from 23 per 100000 people in 2019 to 21 per 100,000 people in 2020 and 2021, being more significant in road traffic injuries - from 8.1 per 100,000 in 2019 to 6.3 per 100000 people in 2020 and 2021.

Conclusions: In Bulgaria, the COVID-19 pandemic and related restrictive measures and social isolation are manifested by a decrease in registered crimes against life and health, an increase in crimes against sexual privacy, a decrease in the death rate from accidents, most significantly in the death rate from road traffic traumatism.

Keywords: COVID-19 pandemic, crimes, mortality

DOI: 10.18332/popmed/165296

Prevalence of postpartum depression symptoms in developed and developing countries in the COVID-19 pandemic: a systematic review with meta-analysis

Marina Vilarim¹, Fernanda Rebelo², Ianne Vieira³, Fernanda Mazzoli², Antonio Nardi⁴, Daniele Marano²

¹Oswaldo Cruz Foundation (Fiocruz), Brazil, ²Fiocruz, Brazil, ³Fundação Oswaldo Cruz (Fiocruz), Brazil, ⁴Federal University of Rio de Janeiro, Brazil

Background: The prevalence of postpartum depression (PPD) possibly increased during the COVID-19 pandemic due to numerous direct and indirect stressors associated with the virus as well as modifications to the social, economic, and health landscape. **Objective:** We aimed to carry out a systematic literature review of cross-sectional studies that assessed the prevalence of PPD symptoms in the pandemic, then meta-analyze and compare the prevalence between developed and developing countries. **Methods:** Studies published on PubMed, Embase, Virtual Health Library, Scopus, Web of Science, PsycINFO and Cinahl from inception to October 2022, that reported prevalence of PPD symptoms, using Edinburgh Postnatal Depression Scale, among puerperal women aged ≥ 18 were included. Quality assessment was performed according to Joanna Briggs Institute Critical Appraisal Checklist. The metaprop command was used in the Stata statistical software v.12.0 to run a random-effects meta-analysis. Heterogeneity was explored by subgroup analysis and meta-regression, considering human development index (HDI), age, time after childbirth, breastfeeding and parity. **Results:** The initial search strategy identified 691 articles. A total of 15 studies with 4788 postpartum women during the COVID-19 pandemic were included. Seven studies were conducted in developed countries and eight in developing countries. The overall prevalence of PPD symptoms was 31% (95% CI: 21.85-40.99). The pooled prevalence of PPD symptoms among women from developed countries [30.5% (95% CI: 16.95–46.02)] did not differ significantly from that in developing countries [31.5% (95% CI: 19.26–45.15)]. In the meta-regression, the proportion of breastfeeding was direct associated with the prevalence of PPD ($\beta=0.006$, $p=0.04$). Studies that analyzed women up to one month after childbirth had a lower prevalence of PPD compared to those that observed them up to one year after childbirth. High heterogeneity was detected across studies.

Institutional care of older people during the COVID-19 epidemic in Croatia

Branko Kolaric¹

¹Andrija Stampar Teaching Institute of Public Health, Croatia

Background and Objective: During 2020 in Croatia there have been two highly stressful events that could have caused professional burnout among nursing home employees: the COVID-19 epidemic and two earthquakes. After the emergence of COVID-19, the Department of Public Health Gerontology at the Andrija Stampar Teaching Institute of Public Health became the coordinator for the preparation of the Guidelines for the Prevention and Suppression of the COVID-19 Epidemic for Social Service Providers in the Social Welfare System incorporating examples of good practice.

Methods: A special team is formed consisting of two specialists in epidemiology and three specialists in public health, three nurses and one IT specialist. The teams tasks were: implementation of official anti-epidemic measures and their coordination in nursing homes in the City of Zagreb, supervision of the implementation of the official guidelines, 24/7 standby telephone, expert consultation of family medicine doctors regarding the application of prescribed measures and vaccines and reporting on the epidemiological situation in nursing homes on a daily basis.

Results: During the peak of the epidemic in 2020/2021, special isolation departments for infected residents were organized in the nursing homes. Due to the well-defined treatment protocols and immediate ensurance of the necessary hospitalizations, we had a low death rate among nursing home residents. Among 8667 infected nursing homes residents in Croatia, there have been 1132 (13%) deaths.

Conclusions: Well-defined protocols and good organisation reduced the number of deaths among nursing homes residents, and later the number of infected residents through the active implementation of vaccinations in nursing homes. Based on the experience gained during the epidemic, we have designed a special two-year program „Control of the consequences of the COVID-19 epidemic and the earthquake in Zagreb in nursing homes“with the quantitative and qualitative research on professional burnout among employees which is still ongoing.

DOI: 10.18332/popmed/165340

Epidemiological profile of children and adolescents with COVID-19 in Tunisia, Mars 2020-August 2022

Fatma Ben Youssef¹, Aicha Hechaichi¹, Mouna Safer¹, Hejer Letaief¹,

Sonia Dhaouadi¹, Emna Mziou¹, Souha Bougatef¹, Leila Bouabid¹, Sondes Derouiche¹, Nissaf Bouafif ép Ben Alaya²

¹National observatory of new and emerging diseases, Tunisia, ²T-Field epidemiology training program, Tunisia

During the COVID-19 pandemic, the proportion of SARS-CoV2 cases and related deaths is lower in children and adolescents than in adults.

Aim: to describe the transmission and severity of SARS-Cov-2 infection among children and adolescents during the different waves of the pandemic in Tunisia.

Methods: A national descriptive study was conducted from March 2020 to August 2022. Data was extracted from the National Database of SARS-Cov2 Cases including those under 18 years of age. The transmission and severity indicators calculated were: cumulative incidence, hospitalization rate, mortality rate and case fatality.

Results: A total of 104517 COVID-19 cases (9.1% of total new cases), 137 deaths (0.46% of total deaths) and 2390 hospitalizations (8.5% of total hospitalizations) were reported among children and adolescents. The cumulative incidence per 100 000 children was 3101.88. The mean age of cases was 11.14 ± 4.85 [0– 17] years with a sex ratio (M/F) of 0.97. The mortality rate per 100 000 children was 4.07. The median age of deaths was 2 months with an interquartile range [0-13 years]. Sex ratio (M/F) was 1.45. The overall case lethality was 0.13%. The overall hospitalization rate was 2.3%. Median age of hospitalizations was 1 month with an interquartile range [4.9-17years]. Sex ratio (M/F) was 1.36. The cumulative incidence was higher among those aged between 15 and 18 years. The crude death rate, lethality and hospitalization rate were higher in the group age [0-5 years]. The epidemic curve showed that the highest incidence was observed during the omicron outbreak (Incidence = 1621.9/100000 children). However, the highest mortality rate was recorded during the Delta outbreak (2.1/100000 children).

Conclusions: Sars-Cov2 infection, associated deaths, and hospitalizations in the pediatric population are not negligible. The highest severity indicators were observed in the youngest age group, thus the need to consider vaccination of children in Tunisia.

Citizen involvement in COVID-19 contact tracing with digital tools: a qualitative study to explore citizens' perspectives and needs

Akke Meer¹

¹National Coordination Centre for Communicable Disease Control, Centre for Infectious Disease Control, National Institute for Public Health and the Environment, The Netherlands

Background and Objectives: Contact tracing (CT) is a key strategy for controlling outbreaks of infectious diseases, including COVID-19. The scale of the COVID-19 pandemic often made it difficult for public health professionals (PHPs) to execute CT adequately. This may be compensated by more actively involving citizens in CT-tasks that are traditionally executed by PHPs (further referred to as 'self-led' CT). However, there is limited insight into citizens' perspectives and needs regarding self-led CT. Therefore, we aimed to explore the perspectives and needs of Dutch citizens regarding self-led CT. We additionally explored if and how self-led CT may be facilitated with digital tools.

Methods: In November 2021, we performed an exploratory qualitative study among Dutch citizens (N=27), in which we conducted online semi-structured interviews. Questions were based on constructs of the Reasoned Action Approach and the Health Belief Model. Interviews were audio-recorded and transcribed verbatim. A thematic analysis was conducted to identify citizens' perspectives and needs regarding participation in self-led CT.

Results: Most interviewees held a positive attitude towards self-led CT and the use of digital tools in this context. Seven main themes related to citizens' perspectives and needs arose from the interviews: 1) 'Perspective on self-led CT influenced by prior experiences with regular CT for COVID-19', 2) 'Anticipated responsibilities in regular CT shape interviewees' perspectives on self-led CT', 3) 'Self-led CT may have various impacts on the execution of CT', 4) 'Perceived self-efficacy to participate in self-led CT', 5) 'Shame and social stigma may hamper participation in self-led CT', 6) 'Concerns about privacy and data security: a barrier for self-led CT', and 7) 'Interviewees' anticipated needs for self-led CT in practice'.

Conclusions: Citizens' attitude towards participating in self-led CT may depend on various factors. Their perspectives and needs should be considered for the future implementation of self-led CT in practice

Brazilian National Front for strengthening long-term care facilities for older people: a necessary and efficient social movement

Karla Giacomini¹

¹Oswaldo Cruz Foundation (Fiocruz), Brazil

Since March 2020, the high mortality rates due to COVID-19 among European residents of long-term care facilities (LTCF) call attention to the need for quick action to avoid this reality in Brazil. The COVID-19 pandemic revealed the invisibility and vulnerability of older people in LTCF. If the situation of the Brazilian ILPI for the elderly was quite fragile before the pandemics, due to the denialist government, it would probably be worse. In April 2020, several older adult human rights groups organized an online group for text, audio, and video communication on how to act quickly against social and health threats to Brazilian LTCFs during the pandemic. As a result, the National Front for Strengthening ILPI (NF-ILCF) was created. The NF-LTCF has 1400 volunteers - supporters and participants - who help care institutions meet these challenges by providing robust scientific evidence, newsletters, training protocols, reports, etc., emphasizing institutional care best practices and gathering information for each LTCF to produce a situational diagnosis and contingency measures against COVID-19. For national coverage, the NF-LTCF uses group communication applications, social media, live online sessions and its website to share materials digitally. In addition, the units can contact the group through WhatsApp groups, email or telephone. The media are designed to provide a friendly, stimulating and encouraging experience. Without financial support, the NF-ILCF initiatives carried out 250 live webinars across the country, disseminated the material to interested parties and ILPI employees (managers, administrators, supervisory technicians, caregivers, cooks, cleaners, nurses, rehabilitators, social workers) on social networks and reached more than 750000 people. Mortality rates in Brazilian LTCF were much lower than expected. This social movement persists in facing prejudice against these institutions, defending the life of each elderly person who resides in them and relentlessly seeking support for a national continuing care policy.

Perceptions on prevention measures for COVID-19 by users of Brazilian basic health units

Kellen Gasque¹, Jonatas Conceição^{2,3}, Fábio Amorim⁴, Magda Mattos⁵, Débora Nascimento⁶, Letícia Goulart⁵

¹Regional Board of Brasília, Oswaldo Cruz Foundation, Brasília, Brazil,

²Regional Board of Brasília, Brasília, Brazil, ³Oswaldo Cruz Foundation,

Brasília, ⁴Superior School of Health Sciences, Health Secretariat Federal

District Government, Brasília, Brazil, ⁵Federal University of Rondonópolis,

Rondonópolis, Brazil, ⁶Fiocruz Pantanal, Oswaldo Cruz Foundation, Campo Grande, Brazil

The behavior of populations in the context of the COVID-19 pandemic is influenced by sociodemographic, health and cultural factors. This study sought to analyze the perceptions and daily practices for the prevention of COVID-19 that were adopted by users of Basic Health Units in the Midwest region of Brazil. This is a cross-sectional study. A total of 403 Primary Health Care users participated in the survey. A block-structured questionnaire covering sociodemographic issues, preventive practices for COVID-19 and sources of information about the infection was applied. A robust Poisson model was generated to determine the factors associated with the perception of avoiding crowding as very important. The most searched sources of information were newspapers and the internet (73.9%), television (65.0%) and social networks (61.8%). Mask use (82.6%), alcohol gel (65.0%) and hand washing (63.0%) were the most adopted preventive methods. The majority (91.1%) perceived social isolation as a very important preventive method against COVID-19, associated with working in an essential service, getting information on TV, considering government officials as reliable source for information and social distancing practice. In addition to the development of health education actions in their territories by the basic health professional teams, it is essential that the health professional assumes the role as a source of health information for the user, as well as develops self- autonomy and the ability to distinguish reliable sources from fake news, whether in the context of the COVID-19 pandemic or in other health situations and their social determinants.

Social skills associated with stress in university students after the return to face-to-face classes

Sol Sanchez¹, Yoshio Gonzalez¹, Hugo Vida¹, Karime Diaz¹, Josue Villegas-Dominguez¹

¹Universidad del Valle de Mexico, Mexico

Background: During the confinement experienced in different countries due to the COVID-19 pandemic, symptoms related to mental health were identified as

a consequence of this stage, such as stress, so it is essential to identify the factors that positively or negatively influence the to start with early identification and attention programs. General Objective: Determine the association between social skills associated with stress in university students after returning to face-to-face classes. Methodology: A cross-sectional, prospective, observational and analytical study was carried out between January and April 2022 in Veracruz-Boca del Río, including university students of both sexes, in face-to-face classes, excluding subjects with a previous diagnosis of stress, anxiety or who do not they wanted to participate. The main variables studied were social skills (degree of assertiveness, communication, self-esteem and decision-making) and stress level. Surveys were conducted using Google Forms, including the social skills test (a.Cronbach 0.75) and the perceived stress scale (a.Cronbach 0.84). Statistical significance was assigned with a value of $p < 0.05$.

Results: 485 participants were included, 83.6% men and 16% women. Sex, age, major studied, and academic degree had values of $p > 0.05$, while other factors (OR/CI95%) such as having an average of 6-7.9 (0.2/0.1-0.6) or 9-10 (1.8/ 1.1-2.9), as well as the degrees of low assertiveness (0.05/0.01-0.1), low average (0.3/0.2-0.9) or very high (2.8/1.3-6.1), low degree of communication (0.2/0.1-0.4) or high average (2.4/1.2-4.8), degree of low self-esteem (0.2/0.1-0.4) or high (3.2/1.5-6.9) and degree of low (0.3/0.1-0.5) and high (2.4/1.3) decisions -4.5) showed values of $p < 0.05$ for the perception of stress. Conclusions: Being a worker is positively associated with the development of stress in students, while school achievement, the degree of assertiveness, communication, self-esteem and decision-making are both positively and negatively associated with the development of stress, according to the intensity of each of these characteristics.

The fight for the human right to health in the COVID-19 pandemic: the political participation of social movements

Denise Diniz¹, Wânia Almeida², Eliane Teixeira³, Marina Souza⁴

¹Instituto Unimed-Rio, Brazil, ²Faculdade de Direito Milton Campos, Brazil, ³ENSP/FIOCRUZ, Brazil, ⁴Faculdade de Medicina Souza Marques (FTSM), Brazil

Background and Objective: Social movements are the root of struggles for the recognition of human rights, which means that these are the fruits of historical struggles for access to material and immaterial goods that are indispensable for a life with dignity. The objective is to survey and analyze the performance of social movements in the construction and realization of the human right to health during COVID-19 pandemic.

Methods: Based on a narrative review of the literature, a critical analysis was carried out on the Brazilian Sanitary Reform Movement (BSRM), the Declaration of Human Rights and the Brazilian Federal Constitution (CFB/88), and the concept of the "Right Found in the Street", as bases for the discussion of three social movements that emerged in the pandemic.

Results: 1st The BSRM emerged in the 1970s, with social movements against the dictatorship, from the interaction between students, intellectuals, health workers and the popular classes, acting as a strong protagonist in the process that generated the CFB/88 and the Unified Health System/1990. 2nd Law can emerge on the street and legality must also emerge from formality, with the participation of civil society, targeting to achieve democratic legitimacy in decision-making. 3rd Thus, the right to health was implemented during pandemic with the participation of slum residents' associations of Paraisópolis/São Paulo, Complexo do Alemão and Morro da Mangureira/Rio de Janeiro, highlighting the hiring of ambulances to assist symptomatic patients and the collection and distribution of food baskets, water and hygiene products.

Conclusions: Social movements can be agents for building the human right to health, at any time, without disregarding other civil society sectors and the international community. It is necessary to recognize and value the micropolitics constituted in the daily life of the territories, facilitating the political participation of social movements in the right's struggle.

Containing Delta in Waikato New Zealand - partnering with Maaori for better outcomes

Richard Vipond¹

¹National Public Health Service Waikato, Te Whatu Ora Waikato, Hamilton, New Zealand

Background: In the Waikato region of New Zealand, the delta variant of COVID-19 disproportionately affected our most vulnerable populations - Maaori, and the less socioeconomically resourced. COVID-19 presented challenges unable to be

prioritised within already complex lives. Historical experiences with government services resulted in a legacy of wariness. Persistence with conventional contact tracing method would perpetuate inequities. New relationships and working pathways were vital in order to successfully control the spread of disease and protect the community. The Waikato response weaved conventional public health approaches with indigenous knowledge (Te Ao Maaori). It was guided by 3 key Maaori values: KAWEA AKE (looking ahead), Manaakitanga (respect and support), and Mahitahi (working as one).

Objectives: 1. Describe the COVID-19 delta outbreak in the Waikato District Health Board region between October 2021 and January 2022, 2. Describe the approach taken to manage the outbreak.

Results: The delta outbreak disproportionately affected Maaori (70% of cases) and low socioeconomic communities (57% quintile 5). The partnership approach was successful in reducing the spread of COVID-19. Delta was stamped out in a number of vulnerable communities and nearly eliminated from the Waikato region. The outbreak response combined Maaori approach with traditional contact tracing methods: 1. Manaaki first - respecting, enhancing and uplifting others in a way that is culturally appropriate and acceptable, 2. Whaanau centered - placing the priorities of affected families at the center of the response, 3. Mahitahi - working together with indigenous leaders through the sharing of power and collaborative decision making, 4. High trust model - shared understanding of expectations and consequences. Conclusions: The Waikato approach is an example of a successful outbreak response model that was equity-centric and committed to the practical application of Te Tiriti o Waitangi principals.

Distress and dependency during meals: the effect of COVID lockdowns on individuals with type-2 diabetes

Márcio Araújo¹, Rejane Costa¹, Vitória Rebouças², Vivian Veras³, Maria Serra⁴, Roberto Freitas¹

¹Oswaldo Cruz Foundation, Brazil, ²Cariri Regional University, Brazil, ³University for International Integration of the Afro Brazilian Lusophony, Brazil, ⁴Maranhão Federal University, Brazil

Background: Social isolation and confinement were some of the public health measures continually employed in several countries around the world throughout the COVID-19 pandemic. Such measures had a strong influence on public health management and care.

Objective: This study sought to understand the influence of lockdown confinements during the COVID-19 pandemic on the eating behaviors of patients with type 2 diabetes.

Methods: A study was conducted via an interpretive-qualitative approach in two primary health care centers located in Eusébio, Brazil, in 2022. We collected relevant patient health information, such as sociodemographic data, quality-of-life indicators, physical activity levels, nutritional status, and overall eating habits. We then carried out home visits to conduct in-depth interviews with 11 patients with type 2 diabetes and poor metabolic control (glycosylated hemoglobin levels $> 7\%$). The data analysis was supported by the software Iramuteq, and by the interpretive description approach.

Results: The sample group mostly consisted of physically active, middle-aged women showing poor glycemic control, and negative experiences linked to the disease. In the patients reports, we verified the prevalence of words associated with strategies of individual diabetes control. During home visits, we uncovered 20 pieces of data related to two main recurring themes: distress and passive dependency regarding their own eating behaviors.

Conclusions: It is necessary to intensify measures of health education aiming at the empowerment of diabetic individuals under confinement regarding the self-management of their eating. This is due to the fact that, in this scenario, these individuals experience feelings of distress and of lack of autonomy over the management of their meal choices and eating patterns.

Surveillance of SARS-CoV-2 in wastewater of Piemonte Region (Italy): trend and relationship to COVID-19 cases

Lisa Richiardi¹, Silvia Bonetta², Cristina Pignata¹, Lucia Decastelli³, Angelo Romano³, Manila Bianchi⁴, Angela Costa⁵, Bartolomeo Griglio⁵, Chiara Pasqualini⁶, Carlo Pietrantonio⁶, Giuseppina Rosa⁷, Elisabetta Suffredini⁸, Elisabetta Carraro¹

¹Department of Public Health and Pediatrics, University of Turin, Italy,

²Department of Life Sciences and Systems Biology, University of Turin, Italy,

³Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d' Aosta,

Italy, ⁴Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d'Aosta, Italy, ⁵Health and Welfare Department, Piedmont, Italy, ⁶Regional Service for Surveillance and Control of Infectious Diseases (SEREMI), Piedmont, Italy, ⁷Department of Environment and Health, Istituto Superiore di Sanità, Rome, Italy, ⁸Department of Food Safety, Nutrition and Veterinary Public Health, Istituto Superiore di Sanità, Rome, Italy

Background and Objective: Wastewater-Based Epidemiology (WBE) is a complementary approach to laboratory-based surveillance for monitoring SARS-CoV-2 circulation and variants, as well as an early warning system for possible new outbreaks. Following Recommendation (EU) 2021/472, since October 2021, a systematic environmental surveillance of SARS-CoV-2 has been activated in Italy. For the Piemonte Region, the study aimed to track virus circulation in local wastewater and evaluate the relationship to COVID-19 cases.

Methods: Raw wastewater samples (n=424) from 6 wastewater treatment plants (WWTPs) covering 44% of the regional population were concentrated via polyethylene glycol precipitation, and viral RNA was quantified by RT-qPCR targeting ORF1b-nsp14. Weekly SARS-CoV-2 concentrations in wastewater were compared with the prevalence rates per 1,000 inhabitants of COVID-19 positive subjects in the WWTPs catchment areas.

Results: Viral RNA was detected in 96.9% of the samples, with concentrations ranging from 4.4×10³ to 1.6×10⁷ genome copies/ (die*equivalent inhabitant). For the period December 2021-January 2022, an increase in the SARS-CoV-2 RNA concentration in wastewater was observed with a clear advance of about 7 days compared to the prevalent cases. In general, good agreement was found between environmental data and prevalent cases during the observation period, even during periods of low prevalence (< 25 cases per 1000 population).

Conclusions: WBE has the potential to effectively integrate laboratory-based and syndromic surveillance because of its ability to describe spatial and temporal trends of COVID-19 at the population level in near-real time. A study is underway to develop a more reliable correlation model with clinical data to make WBE a possible driver for public health decisions. The activities of the SARI network are conducted with the financial support of the Italian Government (Decreto Legge 25.05.2021 n. 73), of Ministry of Health (Program CCM2020) and of EU Commission, DG ENV (Grant Agreement 060701/2021/864481/SUB/ENV.C2).

Glycemic control, self-care, self-efficacy, and knowledge of people with type 1 diabetes using an insulin pump system before and after the COVID-19 pandemic

Vivian Veras¹, Marcio Araújo², Maria Zanetti³, Carla Teixeira⁴

¹University for International Integration of the Afro Brazilian Lusophony, Brazil, ²Oswaldo Cruz Foundation, Brazil, ³São Paulo University, Brazil, ⁴São Paulo University, São Paulo, Brazil

Background: The unique confining experience caused by the COVID-19 changed the normality and daily routine of most of the global population, including people with diabetes, especially their routines of glycemic control, self-care, self-efficacy, and knowledge. Besides that, in handling insulin for diabetes and practices of users under the insulin pump system before and after the COVID-19 pandemic is worrying problem. **Aims:** The current study analyzed the glycemic control, self-care, self-efficacy, and knowledge of people with type 1 diabetes using an insulin pump system before and after the COVID-19 pandemic. **Materials and Methods:** Quantitative, descriptive, and longitudinal study, developed in two phases: the first phase was accomplished in December 2019 (n=50). The second phase occurred from June to December 2021 (n=35) and the participants were contacted through phone calls or using WhatsApp. In both phases, the following surveys were filled: self-care activities with diabetes; a Self-efficacy scale concerning the handling of insulin in diabetes, and an instrument to evaluate the users' knowledge and practices about the insulin pump system. The individual glycemic measures and the scores from the scales were compared before and after the pandemic by using the T-test of Student or Wilcoxon for related samples.

Results: In comparison, it was possible to observe a decrease in the average of glycemia during fasting and the HbA1c (p<0.05). Regarding the self-care, the domains, specific feeding, and physical activity experienced a deterioration after the pandemic. In the self-efficacy scale, all domains got worse after the pandemic. The knowledge experienced a slight decrease in its domains' score averages. **Conclusions:** These results highlight that despite the continuous advances in the care of diabetes, the adequate control in every field in which the disease affects requires a complex task for this public, especially in periods of a health crisis.

Hospital Information System administrative data to identify comorbidity and mortality among hospitalized COVID-19 patients (single center retrospective study)

Iskra Mircheva¹, Martin Mirchev¹, Natalya Usheva¹, Tzonko Paunov²

¹Medical University "Prof. Dr. "Paraskev Stoyanov", Varna, Bulgaria,

²University Hospital "Saint Marina", Varna, Bulgaria

Background: COVID-19 is associated with hospitalization and high mortality rate. Previous studies suggested higher mortality rate in COVID-19 patients with comorbidities, however controversies among different studies about the burden of comorbidity were found. **Objective:** To identify what and to what extend comorbid diseases are associated with hospitalized COVID-19 patients' mortality. **Methods:** A retrospective single-center study was conducted using anonymized HIS administrative data for 71330 patients in the university hospital "Saint Marina"-Varna, Bulgaria, for the period 14/06/2020–31/12/2021. Non-parametric tests and logistic regression were applied at $\alpha = .05$; 95%CI.

Results: Up to seven comorbidities per patient were registered, 9036 for discharged, 4967 for deceased COVID-19 patients. Comorbidities registered for < 30(1.5%) patients were discarded. From 8319 COVID-19 patients, 1809(21.7%) died - 54.3% male; mean age 70.7(SD=11.38); 130(7.2%) had seven, 207(11.4%) had no comorbidities. Deceased comorbid patients had more comorbidities ($z=23.314$; $p<.001$), were older ($z=15.345$; $p<.001$) and had shorter hospital stay ($z=15.749$; $p<.001$). Infectious/Parasitic diseases (A) were registered for 157(8.7%) patients, (157 diseases: A41.9; A04.7; A94.1); cardiovascular diseases (I) registered for 1266(70%) patients (2430 diseases: I11.9; I20.8; I11.0; I48; I50.1; I69.3; I67.9; I13.2; I25.8; I50.1); respiratory diseases (J) - registered for 617(34.1%) patients (651 diseases: J96.0; J80); renal diseases (N) - registered for 192(10.6%) patients (283 diseases: N18.8; N18.9; N40); endocrine/metabolic diseases (E) - registered for 478(26.5%) patients (643 diseases: E11.9; E11.4; E11.7; E78.4); malignant neoplasms (C) - registered for 89(4.9%) patients (92 diseases). Patients with (A),(J),(I),(N),(E) and (C) comorbidities had higher odds of dying (ORA = 20.284; 95%CI=12.371–33.256); (ORJ = 4.08; 95%CI=3.604–4.618); (ORI = 2.752; 95%CI=2.461–3.077), (ORN = 2.866; 95%CI=2.359–3.481), (ORE=1.539; 95%CI=1.362–1.737); (ORC=1.633; 95%CI=1.265–2.107), correspondingly. **Conclusions:** Death with COVID-19 was associated with sepsis, pulmonary, cardiovascular, endocrine, renal and cancer comorbidities, however with lower odds. Monitoring COVID-19 patients for comorbidities is highly recommended to prevent mortality. HIS administrative data can be used for analyses of hospital comorbidity and mortality in pandemics and disasters.

Popul. Med. 2023;5(Supplement):A518

DOI: 10.18332/popmed/165635

COVID-19 and mortality risk factors in a tertiary care center in central eastern Tunisia: a survival analyses

Emna Hariz¹, Hela Ghali¹, Sana Bhir¹, Rania Bannour¹, Souhir Ayadi², Aroua Kamel³, Fatima Khouya³, Arwa Nafetti¹, Sofien Aidani³, Salwa Khfacha¹, Mohamed Rejeb¹, Asma Cheikh¹, Houyem Latiri¹

¹Department of Prevention and Security of Care, Sahloul University Hospital, Sousse, Tunisia, ²Faculty of Medicine of Sousse, Sousse, Tunisia, ³Family Medicine, Faculty of Medicine of Sousse, Sousse, Tunisia

Introduction and Objective: The novel coronavirus illness quickly swept the globe. With a high rate of patients presenting severe acute respiratory syndrome, Tunisia is one of the most affected nations but clinical factors associated with COVID-19 mortality among Tunisian hospitalised patients are rarely studied. Our study aimed to identify independent risk factors of hospital COVID-19 mortality in a tertiary care center since the start of the pandemic.

Methods: An observational prospective study was conducted among confirmed COVID-19 patients who were hospitalized in Sahloul university hospital between September 2020 and November 2022. To identify risk factors of hospital COVID-19 mortality, Kaplan Meier survival analysis and Cox Proportional Hazard regression were used.

Results: A total of 1978 patients were hospitalized in Sahloul University Hospital between September 26th 2020 and November 30th 2022. The mean age was 55.65± 21.39 years [1 – 94]. During the study period, a total of 417 Deaths were reported, with a median survival 30+/- 3.11 days (95% CI [23.904; 36.096]). Mortality was significantly associated with: age ($p< 10^{-3}$), comorbidities ($p= 0.01$), obesity ($p< 10^{-3}$), cardiovascular disease ($p= 0.015$), endocrine pathologies ($p= 0.01$), obesity ($p< 10^{-3}$), hospitalization in intensive care units (ICU) ($p< 10^{-3}$) and Oro tracheal intubation ($p< 10^{-3}$). At multivariable analyses, hypertension (HR 1.93; CI [1.2; 3.72]), cardiovascular disease (HR 4.11; CI [1.99; 17.09]) and being admitted in ICU (HR 31.49; CI [11.04; 72.9]), were independent associated factors with COVID-19 mortality.

Conclusions: The early identification of high-risk COVID-19 patients is mandatory

to decrease this virus morbi-mortality. And this can only be reached by multidisciplinary interventions to solve this public health problem.

DOI: 10.18332/popmed/165638

Brazil's primary health care response to the COVID-19 pandemic

Ligia Giovanella¹, Maria Mendonça², Aylene Bousquat^{3,4}, Luiz Facchini⁵, Fúlvio Nedel⁶, Geraldo Cury⁷

¹Oswaldo Cruz Foundation (Fiocruz), Rio de Janeiro, Brazil, ²Ensp/FIOCRUZ, Brazil, ³FSP, Brazil, ⁴USP, Brazil, ⁵UFPEL, Brazil, ⁶UFSC, Brazil, ⁷UFMG, Brazil

Background: Brazil has more than 33,000 primary health care facilities (PHCFs) which could have played an important role in combating the COVID-19 pandemic. This study examines PHC performance during the pandemic in the country's five macro-regions.

Methods: A cross-sectional study was carried out as a survey using probability sampling of PHCFs. A composite COVID PHC Index (CPI) was generated aggregating 26 variables along four axes: COVID-19 treatment, health surveillance, care continuity and social support. A CPI of 100 would represent best PHCF performance. Factor analysis revealed that the axes reflecting collective actions (health surveillance and social support) behaved similarly, in contrast with those focused on individual actions (COVID-19 care and care continuity). Differences between macro-regions in the CPI and the 4 axes were analysed. Associations between the CPIs and socioeconomic, political and health indicators were examined.

Results: 907 PHCFs participated in the survey. The highest CPI value was observed in health surveillance (70) and the lowest, in social support (59). In the dimension expressing more individual care practices (care continuity and COVID-19 care), a higher value was found among South region PHCFs than among those of the Northeast. The relationship was reversed in the collective dimension: higher values were found in the Northeast. PHCFs with the highest CPIs belong to municipalities with lower per capita income, population and number of hospital beds.

Conclusions: In the absence of national government coordination, PHC potential in the Unified Health System (SUS) was not fully realised. The two performance profiles, with their differing emphases on the individual and collective dimensions, reflect the political projects disputing PHC approaches in Brazil's healthcare system since 2016, as well as structural inequalities between regions.

DOI: 10.18332/popmed/165662

Comparison, by country, of the uptake of COVID-19 vaccination by health care workers in the EU/EEA January - June 2021

Therese McGlacken¹, Therese McGlacken²

¹Department of Public Health, Royal College of Physicians Ireland, Dublin, Ireland, ²Royal College of Physicians Ireland, Department of Public Health, Ireland, Health Service Executive Area C, Dublin, Ireland

Health Care Workers (HCWs) are at high risk of exposure to COVID-19 when providing care to patients. We investigated the uptake of COVID-19 vaccination among HCWs in the EU/EEA and discuss the factors which influence this uptake. The aim of this study was to compare, by country, COVID-19 vaccination uptake by HCWs from January to June 2021, to assist with policy making and prospective planning in these countries during the current pandemic and into the future. The study population included all the countries in the European Union (EU) and European Economic Area (EEA). The secondary data file was downloaded from the European Centre for Disease Prevention and Control (ECDC) website Descriptive and comparative data were analysed and presented using Excel and Chi-square test of hypothesis. The percentage of HCWs in EU/EEA countries ranged from 1.2% to 5.1% per population. From January to June 2021, the percentage of first and second dose vaccinations of HCWs ranged from 20% to 100% and from 21% to 100%, respectively. The Comirnaty–Pfizer/BioNTech vaccine (COM) was the most administered vaccine in all EU/EEA countries, followed by the Moderna mRNA-1273 vaccine (MOD) and the Astra-Zeneca–Vaxzevria vaccine (AZ). The Janssen–Ad26.COV 2.5 vaccine (Janss) use ranged from 0.1% to 4.8% for the one dose vaccine. In January 2021, a median of 29% of HCWs received their first dose of COVID-19 vaccination. Italy was the only country with a mandatory vaccination policy for HCWs. Vaccination uptake rates were statistically different among EU countries ($p < 0.05$). Data such as these could be used in mathematical modelling potential future pandemics to predict vaccine up-take by selected, exposed, vulnerable sectors of the population, for whom it is relevant.

Implementation of the international health regulations during the COVID-19 pandemic, a scoping review

Daniel Saldanha Resendes¹, Eunice Crisóstomo², Inês Mendes Pacheco³, Marcelo Godinho², Joana Miguel Carvalho⁴

¹ACES Lisboa Central Portugal, ²ULS Litoral Alentejano, ³ACES Tâmega II Portugal, ⁴ACES Entre Douro e Vouga I

Background and objective: The International Health Regulations (IHR) is a legal instrument that sets out to control infectious disease epidemics worldwide and that makes countries accountable for monitoring and notifying the World Health Organization (WHO) of any event that could constitute a public health emergency. The COVID-19 pandemic set an unprecedented challenge to the IHR commitments and so this scoping review sets out to identify the challenges, successes and limitations of the IHR during the COVID-19 pandemic.

Methods: We conducted a scoping review following a PRISMA methodology of the following online databases and sources: PubMed and SCOPUS. Only articles mentioning both IHR and COVID-19 were eligible. Eligible articles were then read by two reviewers independently and in duplicate. A total of 15 articles between 2020 and 2022 met the criteria and were included.

Results: Most articles refer to the IHR as still a vital instrument in Public Health action especially in Health Emergency situations, but most countries faced limitations in its implementation during the COVID-19 pandemic. Reinforcing the global health security strategy, reviewing the IHR to address current challenges and strengthening the commitment of countries and states to comply with its resolutions, are key lessons mentioned.

Conclusion: The lessons learned from this scoping review should act as a warning sign that the IHR should be reviewed and updated to meet current societies' requirements. A more effective response grounded on the IHR is needed to face upcoming and expected events of COVID-19's magnitude and severity.

Vaccination in children under 6 years old and the impact of the covid 19 pandemic. Cartagena, Colombia

Irma Castillo Avila¹, Luis Alvis Estrada¹, Edna Gómez Bustamante¹

¹Universidad de Cartagena, Colombia

Background: Childhood vaccination is a widely used strategy to reduce the population impact of vaccine-preventable diseases. Some social circumstances can significantly affect the coverage and achievements of immunization programs. Objective: Determine vaccination coverage before and after the pandemic in children under 6 years old in the Cartagena district.

Methods: A descriptive study was performed. The vaccination coverage of the biologics included in the national vaccination program was evaluated. A total of 3,829 boys and girls under 6 years old were included, using random cluster sampling. Two coverage measurements were made: one in 2019 and one in 2022. Descriptive statistics were applied to the data.

Results: The highest vaccination coverage is presented in the newborn doses (Anti-tuberculosis (BCG) and Anti-hepatitis B) with 99.6% for the year 2019 and 100% for the year 2022. The biologicals with the lowest coverage are the 5-year reinforcements (Antipolio and reinforcement against Measles, Rubella and Mumps), with percentages of 68.4% and 69.3% respectively. In all the biologicals, a coverage reduction of 11% on average is observed for the year 2022. The main reason for not vaccinating is the lack of time for parents and caregivers to attend consultations, mainly due to the restrictions derived from the COVID 19 pandemic. Conclusion: Vaccination coverage depends on the availability of parents and caregivers to attend the consultations. A greater impact due to the restrictions of the COVID 19 pandemic is observed.

Public perception and perspective towards COVID19 vaccination among students of University of Debrecen

Phuong Nguyen Thi¹

¹University of Debrecen, Hungary

Background: COVID19 pandemic is most remarkable concern since early 2020. Public Health has constantly made effort to alleviate the crisis. Vaccination is one of the ultimate control methods of COVID19 that were created at incredibly rapid rates. The implication of vaccines comes with divergent opinions. To maximize the coverage, the understanding of perspectives towards the vaccination is crucial. No health promotion campaign can achieve its goals without local adjustment. The study was conducted with students in University of Debrecen to investigate local tendencies and to suggest the vital local adjustments when promoting vaccines.

Objective: The study aims to investigate the perceptions and perspectives towards COVID19 vaccinations among students in University of Debrecen. Motivations, beliefs and concerns on taking COVID19 vaccination are the major focus to study the decision-making process and the crucial factors behind.

Methods: A cross-sectional survey was launched at the end of 2021, in the third outbreak with 386 students from University of Debrecen. The questionnaire was distributed online and in-person. The key factors are demographic features, common beliefs and concerns about vaccination. The tendencies, levels of acceptance and the potential decision-turning factors were identified.

Results: Among 386 participants, 87% believed that COVID19 vaccines are necessary. However, around 45% are concerned by being vaccinated. Information and emotion are the most important in decision making, 88% agreed that unreliable news affects their choices and 47% consider social media to be worrying for them. Side effect and controversies play a significant role in public perspective. Valid and consistent information source was confirmed to ease the unrest about vaccination.

Conclusions: The findings suggest the positive sides of vaccination situation and suggest space for improvement. Naming hesitations and missings in trust-building, we can elaborate the interventions for certain areas, demographic groups; equip the young with health protecting skills and improve health literacy.

Repercussion of the covid-19 pandemic on academic activity in graduation in health in a private education institution

Caroline Castro¹, Margareth Conceição², Bárbara Lacerda¹, Marcos Silva¹, Jeanine Barbosa², Dherik Santos³, Jeremias Simões¹, Rafael Caliarí¹, Rita Lima¹, Maria Andrade¹

¹Universidade Federal do Espírito Santo, Programa de pós-graduação em saúde coletiva, Brazil, ²Universidade Federal do Espírito Santo, ³Universidade federal de catalão, Departamento de medicina, Brazil

Background: During the COVID-19 pandemic, quarantine and other prevention measures impacted the educational system by affecting the preparation and the quality of teaching.

Objective: To identify factors associated with the discontinuance of academic activities by students due to funding issues in the context of the pandemic.

Method: This quantitative, exploratory cross-sectional study was carried out in a private higher education institution (HEI) in the city of Vitória, Espírito Santo (ES), Brazil. Data was collected through google forms from Nov/2021 to Jan/2022. Analysis was made with SPSS Statistics version 24 and STATA version 15.1 programs.

Results: 846 students participated in the research, 52% of the students enrolled at the HEI in 2021, with an average age of 22 years, 75.3% women, 63.1% white, and 54.3% from social class A, of which 80.5% of students do not work. Results showed that 9.46% students were unable to complete academic activities due to tuition issues, of which the majority were brown/black unmarried women, without a job, enrolled in the social service program, from social class B, with an income of up to 3 minimum wages, and received financial support from a family member aside from student grants.

Conclusion: This study contemplates the multifunctional role of women in society, as well as the difficulties they encounter. It was demonstrated that, although student grants promote social protection, they alone were not enough to prevent the cessation of academic activities. It is necessary to carry out an analysis considering the different intersections that relate to women's experiences in the COVID-19 pandemic due to economic and political instability in Brazil, reinforcing inequalities in educational public policies for women.

COVID-19 and life expectancy in Mexico between 2019 and 2021

Guillermo Gonzalez-Perez¹, Maria Vega-Lopez¹

¹University of Guadalajara, Mexico

Background/Objectives: Life expectancy at birth (LEB) is an important indicator of the health status of a population. Recent studies have shown the reduction of the LEB in different countries due to the COVID-19 pandemic. In this sense, this study aims to identify the impact of COVID-19 on life expectancy in Mexico in the year 2021.

Methods: Abridged life tables by sex were constructed for Mexico in 2019 and 2021. Using the Arriaga method, the years of life expectancy lost (YLEL) were estimated between 0 and 85 years due to COVID-19 and selected causes in each year. Adjusted mortality rates from these causes were calculated for the period 1998-2021 and their trend was analyzed using a "joinpoint" regression analysis

Results: The male LEB decreased 5.2 years and the female 4.1 years between 2019 and 2021. COVID-19 was directly responsible for 4.3 YLEL in men and 2.8 in women between 2019 and 2021, but in other causes of death such as diabetes mellitus (DM), ischemic heart disease (IHD) and acute lower respiratory infections (ALRI), a substantial increase was also observed in YLEL between both years. The trend analysis reveals for all the analyzed causes an upward inflection point at the end of the period studied, with a marked statistically significant annual percentage change.

Conclusions: The COVID-19 pandemic has reduced LEB in Mexico, especially in men; These figures are higher than those found internationally. In addition to the YLEL directly due to COVID-19, the YLEL due to other causes studied also reflect the impact of the pandemic in Mexico. While the prevalence of DM and IHD in the Mexican population is high, strategies to reduce the impact of the pandemic necessarily involve achieving greater control of these diseases in patients who suffer from it and trying to reduce its prevalence.

Prejudice and discrimination faced by nursing professionals in their community during the COVID-19 pandemic

Stephanía Mendes Demarchi¹, Fabiane Lima Simões¹, Jeremias Campos Simões¹, Marcos da Silva cordeiro¹, Jeanine Pacheco Moreira Barbosa¹, Caroline Feitosa Dibai De Castro¹, Rafael Vulpi Caliarí¹, Gabriela de Brito Martins¹, Rita Duarte Lima¹, Maria Carvalho Andrade¹

¹Universidade Federal do Espírito Santo, Brazil

Introduction: In the context of the pandemic, additionally to the already known effects of the disease, many suffer from prejudice and discrimination related to COVID-19, which are usually motivated by fear and uncertainty based on distorted perceptions of risk. Among others, this treatment can negatively affect health professionals.

Objective: To describe situations of prejudice and discrimination faced by nursing professionals during the COVID-19 pandemic

Methods: Qualitative and descriptive research, for data collection interviews were conducted with a semi-structured script with 40 participants.

Results: 17 participants (42.5%) reported episodes of prejudice or discrimination in their communities. The reports are diverse and took place in different places such as banks, supermarkets, bakeries, or the home environment of family members. Such reports included: "they moved my chair away from me when I went to the bank", "they did not want to sit next to me on the bus", "the neighbor crossed the street when he saw me", "I was not invited to an event with family and friends", "feeling looks towards me when entering the establishment", "people with expressions of fear when they see me", "they separated the household items for me to use at my mother-in-laws house", "they refused to enter the elevator with me", "condominium where I live with an elevator exclusive for me", "my relatives were afraid of my children", "they refused to see me at the beauty salon".

Conclusion: Considering the social panic caused by the high mortality rates, and the fact that it is a recent and unknown disease, the population has become afraid and concerned about the contagiousness of the disease. Information distorted from reality, fake news, and wrong approaches to dealing with the pandemic can exacerbate prejudice and discrimination by part of the population.

Effects of the COVID-19 pandemic on access and delays in care for people with diabetes

Adesola Odiah¹

¹Central michigan university, 21 arnold court, east rockaway, ny 11518, united states

Background and Objective: During COVID-19, health and coverage restrictions, increased healthcare system demands, and patient uncertainty were important barriers to uninterrupted diabetes care. Diabetes patients are solely responsible for managing their disease through on-time access to care, proper diet, glucose monitoring, and medication. The present study was designed to examine the effect of socioeconomic variables such as employment and insurance change, on patient-self-reported delays in access to medical care, difficulties obtaining medication, forgoing CGM/Insulin pump (and refilling), for diabetes patients in the US, during the pandemic.

Methods: This cross-sectional study used secondary data of 2,595 U.S. diabetes patients (December 2020, thrivable survey). The analysis examined associations between insurance change and type, employment, income, and patient education, with the following outcomes: (i) delay in care, (ii) difficulties in obtaining medications, (iii) foregoing CGM/Pump, (iv) foregoing refilling CGM/

Pump. Bivariate statistics were first conducted, followed by multivariate analysis using binary logistic regression in spss.

Results: Patients with recent insurance status changes were 1.5 times more likely to report delays in care, 33% more likely to experience difficulties obtaining medication, twice more likely to forego CGM/Insulin pump, and four times more likely to forego refilling CGM/Insulin pump. Those with a recent employment change were 1.5 times more likely to have delays in care and difficulties obtaining medication, while those without insurance were twice as likely to have difficulty obtaining medication. Education, unemployment, and income were also found to be associated with challenges in seeking diabetes care.

Conclusion: Diabetes patients experienced challenges during the pandemic, which can be attributed, to an extent, to socioeconomic factors. Statewide policies need to be established for non-delayed access to diabetes care in times of crisis, such as during the recent pandemic.

Building on local strength: the Philippine toolkit on community-based management of COVID-19

Miguel Dorotan¹, Romelei Alfonso², Aileen Espina³, Paolo Medina⁴, Gabriele Domingo², John Abadiano⁵, Maria Medina⁵

¹Alliance for Improving Health Outcomes (AIHO), Philippine Society of Public Health Physicians (PSPHP), Philippines, ²Alliance for Improving Health Outcomes (AIHO), ³Foundation for Family Medicine Educators, World Organization of Family Doctors (WONCA), Philippines, ⁴University of the Philippines Manila College of Medicine, Philippine Academic Society of Social and Community Medicine (PASCOSM), Inc., AIHO, Philippines, ⁵Zuellig Family Foundation, Philippines

Background: In the Philippines, the earliest pandemic response has been hospital-centric. With looming hospital congestion, a group of public health professionals urgently asserted that the community should be the first line of defense. Volunteers convened to contextualize evidence and practice to the Philippines' decentralized governance setting, anticipating the need for non-existent operational guidance.

Method: A Viber group allowed rapid consultation between public health convenors, technical experts, and local government implementers to determine knowledge needs and tailor-fit guidelines for COVID-19 response, guided by these principles: existing disaster response structures must be activated, primary care resources must be mobilized, and the Filipino family/household as the unit of care must be recognized. The modified Delphi method was used to refine and finalize contents. Modules have been iterated based on user feedback.

Results: The Community Based Management of COVID-19 (CBMC) toolkit was consolidated in eight weeks. Its four modules contain slide decks, user manuals, and implementation checklists. The first centers on local Disaster Risk Reduction and Management - Health (DRRM-H) for Emerging and Reemerging Infectious Diseases (EREIDS) using disaster response strategies that local governments are already familiar with. The second contains clinical algorithms to guide primary care providers in low-resource settings. The third details the operations of a community-run isolation and treatment facility. The fourth provides a family-oriented approach to COVID-19, including for special and vulnerable groups. Overall, this ensured that the Barangay (village) Health Emergency Response Teams and the primary care system with its community-managed isolation and treatment facilities, take central roles. This strengthened local response and pulled away strain from hospitals.

Conclusion: The CBMC framework was eventually adopted and institutionalized by the Philippine government for the local government COVID-19 response. This initiative reasserts that pandemic response should empower local communities by building on their local resources and strengthening existing systems and institutions.

Investigating Nurses' Perceptions of Organizational Resilience due to COVID-19 Pandemic

Eliza Wong¹, Annie Cheung¹, Zoe Tam¹, Eng-Kiong Yeoh¹

¹The Chinese University of Hong Kong, Hong Kong

Background and Objective: The challenges including healthcare materials supply shortage, inadequate manpower, patient overload etc have happened in worldwide healthcare organizations during the COVID-19 global pandemic. Organizational resilience in the healthcare setting thus is an important issue to review which enables healthcare organizations to plan, retain and recover to their normal function even in a crisis. The study aimed to explore views on organizational resilience from nurses' perspective due to the Omicron impact in Hong Kong.

Method: A qualitative study design was adopted to understand nurses' experience on how their organizations responded to the wave of Omicron. To capture a breadth of diverse experience of the nurses and enrich the findings, a heterogeneous sampling in terms of ranks of nurses and working settings in both public and private sectors were considered for the recruitment. The interview was guided by a semi-structured discussion guide and qualitative content analysis with an inductive approach was applied.

Results: A purposive sample of 22 nurses were recruited to participate in the individual interviews between March and June 2022. Most of the nurses expressed that the capability of nurses was good enough in local healthcare settings during the pandemic due to the pre-pandemic training and previous SARS experience. However, the overall nurse capacity was lower than expected because of the patient overload and staff sickness absence at the beginning of the Omicron wave. The respondents also picked "preparedness and planning" as the main factor influencing the organisation's resilience and "Leadership practice" was followed. Conclusion: The findings indicate the key challenges that local healthcare organizations faced during the pandemic. It also provides insights for the management team to better rethink and transform their organizations for managing the effectiveness and continuity of the healthcare systems in disaster in future.

Uptake of non-mandatory bivalent COVID-19 booster vaccine among healthcare workers: results from an Italian teaching hospital

Eleonora Marziali¹, Mario Nurchis², Domenico Pascucci³, Alberto Lontano⁴, Giuseppe Vetrugno², Umberto Moscato³, Gianfranco Damiani³, Patrizia Laurenti³

¹Università Cattolica del Sacro Cuore L.go F. Vito 1, 00135 Roma (RM), Italia Italy, ²Università Cattolica del Sacro Cuore, ³Università Cattolica del Sacro Cuore / Fondazione Policlinico Universitario "A. Gemelli" IRCCS Italy, ⁴Università Cattolica del Sacro Cuore Italy

Background and Objective: In September 2022, the bivalent Comirnaty Original/Omicron BA.4-5 vaccine was authorized for use as a booster dose for individuals aged 12 years and older. The aim of this retrospective study was to assess the acceptance of the fourth dose among healthcare workers (HCWs) of an Italian teaching hospital and to describe changes in uptake trend compared with the previous COVID-19 vaccination campaigns, considering that the fourth dose is not mandatory.

Methods: Pearson's X2 test was used to test the correlation between the fourth dose vaccination rate and the previous doses vaccination rate. A linear regression model was adopted to predict fourth dose vaccination coverage. Multivariate logistic regression was performed to investigate the influence of sex, age, and occupation on vaccination uptake.

Results: Overall, 8159 employees were included in the study. Among them, 1077 received the bivalent booster dose between September and December 2022. Compared with men, women had a lower tendency to receive vaccination, but this difference was not statistically significant. The mean age at the time of vaccination was 44.1 years, and the probability of vaccination increased significantly ($p < 0.001$) as age increased. The logistic regression showed that being a physician is significantly ($p < 0.001$) associated with higher uptake compared to nurses (OR 0.25, 95%CI 0.20-0.31), other HCWs (OR 0.21, 95%CI 0.16-0.27) and administrative employees (OR 0.33, 95%CI 0.25-0.42). In contrast, working in low-risk, medium-risk or high-risk operating units did not affect vaccine uptake significantly. When analyzing the uptake of previous COVID-19 vaccine doses, the expected value, according to the linear regression model, was estimated to be 30.7%, but the observed value was significantly lower (13.0%).

Conclusion: To mitigate the socio-economic and health effects of COVID-19, it is critical to further promote vaccination of HCWs, given their crucial role in vulnerable settings.

Background: Healthcare-associated infections (HCAI) are considered a major challenge worldwide, a public health risk and an economic burden. Besides hand hygiene practices, the strategies to prevent HCAI include the use of disinfectants and cleaning of high-touch surfaces which favor microbial transfer by hands. The emergence of novel pathogenic viruses and antibiotic-resistant bacteria have prompted research into developing alternative microbial materials such as plastics with long-term biocidal activity in nanostructured bulk material. Currently, there is a large amount of literature on multifunctional nanocomposites with improved mechanical and antimicrobial properties against bacteria and fungi, whilst data against viruses are lacking. This study aims to assess the in vitro virucidal activity of three epoxy/clay nanocomposites against viruses transmitted by salivary droplets and/or through contact with contaminated objects/surfaces. **Methods:** Two natural clays from Morocco were used to reinforce the epoxy resins with 1% and 5% wt, achieving the clay dispersion by milling and mechanical stirring. A third nanocomposite was obtained adding 1, 3 and 5% wt Cloisite® 15A, a commercial montmorillonite, organically modified, containing quaternary ammonium chloride.

Results: To date, only the experimental protocol has been developed. Four viruses will be tested: Human Coronavirus OC43, as a SARS-CoV-2 surrogate, Herpes Simplex Virus 1, chosen for its low environmental resistance and for its rapid in vitro growth, Human Adenovirus type 5 and Monkeypox Virus, chosen for their high environmental persistence and resistance to treatments. Tablets of each nanocomposite and epoxy resin as control will be contaminated and after defined contact times the residual virus will be recovered and quantified by end-point titration.

Conclusion: Our study could lead to the development of innovative epoxy/clay nanocomposites with virucidal activity for potential use in end-products such as food packaging, medical devices or hospital furniture, opening interesting perspectives in the treatment of surfaces potentially contaminated by viruses.

Environmental surveillance of Sars-Cov-2 in wastewater in Apulia region, Southern Italy

Francesca Apollonio¹, Osvalda De Giglio², Francesco Triggiano³, Giuseppina La Rosa⁴, Elisabetta Suffredini⁴, Luca Lucentini³, Nicola Ungaro⁵, Giuseppe Di Vittorio⁶, Neeludoff Albano⁶, Onofrio Mongelli⁶, Maria Montagna¹

¹Interdisciplinary Department of Medicine, University of Bari Aldo Moro, Piazza G. Cesare 11, 70124 Bari, Italy, ²Interdisciplinary Department of Medicine, University of Bari Aldo Moro, Piazza G. Cesare 11, 70124 Bari, Italy, ³Department of Environment and Health, Istituto Superiore di Sanità, 00161 Rome, Italy, ⁴Department of Food Safety, Nutrition and Veterinary Public Health, Istituto Superiore di Sanità, 00161 Rome, Italy, ⁵Agency for the Environmental Prevention and Protection (ARPA Puglia), Corso Trieste 27, 70126, Bari, Italy, ⁶Department of Health Promotion and Animal Welfare, Apulia Region, Bari, Italy

Background and Objective: Monitoring SARS-CoV-2 in untreated wastewater can provide an early warning system for virus circulation. The Istituto Superiore di Sanità coordinates the SARI project (Environmental surveillance using wastewater in Italy) in Italy which enlists 18 Regions and two Autonomous Provinces. The activities were carried out with the financial support of the Italian Government (L.D. 25.05.2021 n.73), and the European Commission, DG ENV (Grant Agreement 060701/2021/864481/SUB/ENV.C2). The study aims to: 1) predict the number of COVID-19 cases/100,000 inhabitants in the 15 days after SARS-CoV-2 detection in wastewater 2) investigate the factors influencing the presence of the virus in wastewater.

Methods: Overall, 16 wastewater treatment plants (WWTPs) were enrolled in Apulia Region (Southern Italy), serving municipalities with 50,000-150,000 inhabitants (14 WWTPs) and >150,000 inhabitants (2 WWTPs). Sampling was carried out weekly or biweekly, respectively, by Regional Agency for Protection of Environment. The laboratory analyzes were performed according to national SARI protocol. A ROC curve model was applied to predict number COVID-19 cases and a Poisson Regression model was used to investigate the factors influencing the viral presence/load in wastewater.

Results: From October 2021 to July 2022, 607 samples were analyzed, of which 592 (97.5%) tested positive for SARS-CoV-2. The statistical analyses showed that at least 11 COVID-19 cases/100,000 inhabitants served by WWTP would occur after a wastewater sample resulted positive for SARS-CoV-2. In the period January-July 2022, winter months were associated with a higher probability of virus detection. An inverse correlation was found between the SARS-CoV-2 load in wastewater and the range of atmospheric temperature and mean atmospheric pressure/sampling day.

Conclusions: The presence of SARS-CoV-2 in wastewater can be used to predict COVID-19 cases, supporting the potential of wastewater-based epidemiology. However, further studies are required because our predictive model remains limited for the complexity and uncertainties associated with the process.

Cesare 11, 70124 Bari, Italy, Italy

Background and Objective: The transmission of SARS-CoV-2 occurs through direct contact (person to person) and indirect contact by means of objects and surfaces contaminated by secretions from individuals with COVID-19 or asymptomatic carriers. In this study, we evaluated the presence of SARS-CoV-2 RNA on surfaces made of different materials located in university environments frequented by students and staff involved in academy activity during the post pandemic era.

Methods: A total of 679 surfaces samples were collected from classrooms, computer room, desks, common areas from May to November 2022 between 1.00 and 2.00 p.m. Standard sanitation of all university areas was carried out at the end of all work activities. Swab samples were subjected to Real-Time Reverse Transcription to evaluate the presence of SARS-CoV-2 RNA by amplification of ORF-1ab gene (nsp 14). Cell cultures were set up for the isolation of SARS-CoV-2 and to demonstrate virus viability.

Results: Overall, 41 (6.09%) swabs resulted positive for SARS-CoV-2 RNA with a median Ct value of 38.12 [IQR: 36.4–39.48]. All examined samples resulted negative after viral culture, since no cytopathic effect was observed. The number of positive samples was directly proportional to average number of COVID-19 cases/week (Poisson regression Intercept $\beta = 1.217$; $\beta = 0.000227$; $p < 0.0001$). Statistically significant difference were found between number of positive swabs for number of students/classroom (Fisher's exact $p < 0.05$). In the summer-autumn the number of positive samples (7.3%) was higher than in the winter (3.3%) ($\chi^2 = 3.92$; $p < 0.05$).

Conclusion: Screening of environmental samples for the presence of virus provides evidence of the number of infected people shedding the virus in the vicinity. Environmental monitoring of SARS-CoV-2 RNA could effectively support public health prevention strategies in the academic and school world. Also, when compared with clinical-testing protocols, it could streamline all procedures related to informed consent, sample collection and operational logistics.

Background and Objective: COVID-19 can evolve into severe clinical manifestations requiring hospitalization in intensive care unit (ICU) where antibiotic therapy is extensively undertaken. Antimicrobials use was evaluated in relation to the outcomes (transfer in other wards/death) in COVID-19 patients in ICU between May 2020-July 2022 in Molise region, central Italy.

Methods: Data were obtained from clinical records and internal ward software. A descriptive and univariate analysis was performed through SPSS v28.0 setting p2 antibiotics, and a significant relation with outcome was observed, as 86% and 98% deaths occurred among who took ≤2 and >2 antibiotics, respectively. Further differences were found between outcome and treatment with azithromycin, meropenem, ceftaroline, linezolid and teicoplanin. Polypharmacotherapy with ≥3 antibiotics was more common in male patients (81.3% vs 18.7%), while no differences with respect of age <65 and ≥65 years emerged.

Conclusions: Most patients were male who had largely received polypharmacotherapy due to high predisposition to severe COVID-19 according to national studies. Azithromycin did not show effects on disease evolution, and none of the broad-spectrum therapies had a significant impact on clinical improvements. The association between death and minor drug intake should be considered in the light of the complexity of patients and underlying diseases, suggesting a marginal impact of antibiotic therapy on COVID-19 outcomes.

Introduction: This study gives insight to work processes in health. It presents letters, chronicles and writings about the activity of community health agents (CHA) who, in their field, have strengths, desires and aspirations. The study was based on Yves Clots clinic of activity and used Michel Foucaults theory of ethics of self-care. Thus, this study proposes a correlation of the clinic of activity, by Yves Clot, and Registration, by Conceição Evaristo, in the construction of narratives and writings of the agents daily work, in a self-confrontation of the activity as a living triad.

Objective: To analyze the daily encounters of Primary Care in the city of Vitória, ES, during the COVID-19 pandemic, from the perspective of community health agents. **Methods:** Focus groups, Interviews and Participant observations were carried out, subdivided into 3 stages, which culminated in the preparation, sharing and self-confrontation of letters/chronicles.

Results: Writings from a perspective of self, work and the collective constitute directions for analysis and construction of a policy of resistance and (re)existence of health workers, in a context of the COVID-19 pandemic. The study focused on the pandemic as an analyzer of relationships, public policies, the intensification and precariousness of working with health. The results show limitations to both have and execute activities, overloads and uncertainties, differences in womens work and their intersections, but they also show, mainly, ways to escape and deviate, in other words resistances and (re)existences of making history and caring for women agents in health communities.

Conclusion: When experimenting with writing about experiences, in a pandemic context, the CHAs self-confront and characterize the work for community health agents, as a form of reinventing work and health production, led by the (re) flourishing of those who take part in this practice.

Santo., ⁴Postgraduate Program in Collective Health, Federal University of

Espírito Santo Brazil

Introduction: The COVID-19 pandemic imposed the need for social isolation on the communities of the samba schools, with consequences for meetings, coexistence and forms of grouping between the components. Samba schools are part of the Brazilian black cultural heritage. This research is an excerpt from the master's thesis in Collective Health.

Objective: To analyze narratives of members of a samba school community about and their experiences in the context of the Coronavirus pandemic.

Methodology: Exploratory research. Qualitative approach. Chosen a samba school in the city of Vitória, Espírito Santo - Brazil. Inclusion criteria, over 18 years old, being an effective member of the samba school and residing in the territory. For the sample, a snowball technique with theoretical saturation was used. Semi-structured interviews were conducted. All interviews were recorded and later transcribed and analyzed.

Results: 8 semi-structured interviews were carried out, all participants declared themselves to be black, living in neighborhoods on the outskirts and in the favela. Among the analysis categories, the interviewees pointed out the difficulty of carrying out social isolation, due to the precariousness of the residences and the size of the families. The absence of activities at the samba school mobilized categories such as "mental illness" caused by "sadness" and "emptiness" by the absence of the samba school environment. In addition to feelings of "mourning", "loss" and "deaths".

Conclusion: The members of the samba schools worked with civil society, particularly with their communities, aiming to face the pandemic, publicize and promote vaccination and social assistance for their members. Social isolation imposed that many families, in addition to facing the challenges of the pandemic, could not experience their moment of mourning.

Barriers to leisure-time physical activity during the covid-19 pandemic: results from the longitudinal study of adult health (elsa-brasil)

Maria de Almeida¹, Maria de Almeida², Estela de Aquino³, Sheila de Matos⁴, Ana Patrão⁵, Rogerio de Almeida⁶, Ciro Queiroz⁷

¹Instituto Gonçalo Moniz - FIOCRUZ Rua Waldemar Falcão 121 - Candeal

Brasil, ²Instituto Gonçalo Moniz - FIOCRUZ Rua Waldemar Falcão, 121 -

Candeal Brazil, ³Universidade Federal da Bahia, ⁴Universidade Federal da

Bahia Brazil, ⁵Universidade do Porto Portugal, ⁶Universidade Estadual de

Feira de Santana, ⁷Universidade Estadual do Sudoeste da Bahia, Brazil

Physically inactive populations are more exposed to the occurrence of chronic non-communicable diseases and to a higher risk of complications from COVID-19. During the pandemic, health behaviours in the adult population changed, including the practice of leisure-time physical activity (LTPA). The objective of this work is to identify barriers to the practice of physical activity in leisure-time during the COVID-19 pandemic. In 2020, a survey on COVID-19 was carried out with participants from ELSA-Brasil. 5,639 civil servants from 5 Brazilian teaching

and research institutions were interviewed, and 57.7% of whom were women. The median age was 59 years. LTPA during the period of social distancing was reported by 46.2% of the participants, however, 19.0% of those who did it in the pre-pandemic period stopped doing it. Among those engaged, 53.0% were women, half of them were married, 30.2% cared for children or the elderly, 71.3% reported meeting the recommendations to stay/work at home and 46.5% increased weight. Among the physically inactive, 45.0% were married, 70.1% complied with the recommendations to stay/work at home, 37.5% took care of children or the elderly, 50.8% gained weight and 97.6% performed housework. The profile of men is similar except that around 80.0% of them, active or inactive, were married. According to the results, the COVID-19 pandemic decreased the practice of LTPA among study participants. The inactive men and women performed more household chores, took care of children and the elderly and had an economic impact on the family, whether due to the loss of a source of income or because a member was left without a job, constituting possible barriers to the practice of LTPA. This finding could be used in the elaboration of policies aimed at promoting health by focusing on different aspects of barriers to LTPA.

Sociodemographic and clinical profile for the tests used for the diagnosis of covid-19 in the state of Rio de Janeiro, Brazil - 2020 to 2021

Gabriella Nazario¹, Silvia Cardoso², Felipe Tavares¹

¹Universidade Federal Fluminense Brazil, ²Secretaria de Estado de Saúde do Rio de Janeiro

Background: Testing is an important pandemic control tool for covid-19, allows the identification of vulnerable populations and regions, where strategies can be adopted both for intensification and relaxation of control actions. in Brazil, access to health services is unequal, consequently, access to tests for covid-19 may be hampered for different population profiles.

Objective: Describe the frequency of each type of diagnostic test performed for covid-19 in residents of the state of Rio de Janeiro according to sociodemographic and clinical characteristics.

Methods: Cross-sectional descriptive study with a quantitative approach, using secondary data from the esus notifica database, where suspected cases of covid-19 are reported. the study population is individuals notified to the system, residents of the state of Rio de Janeiro and who have undergone some test. the frequency distributions of the studied population were described by sex, race/color, age group and health region of residence, health conditions and symptoms, according to the type of test performed. the research period was from 2020 to 2021, divided into 4 semesters, according to the offer of tests and change in testing criteria guided by the ministry of health.

Results: The year 2020 the most used test was the rapid antibody test, in the first half of 2021 was rt-pcr and in the second the rapid antigen test. in relation to rt-pcr, in all periods the indigenous race/color presented the lowest percentage and the white race/color the highest. under 20 s of age have higher percentages for rapid antigen or antibody tests.

Conclusion: The temporal change of the guidelines on testing from the ministry of health was observed. there was a difference in access to the tests between the categories of race/color, age groups and health regions studied. to reduce iniquity, specific actions must be taken for each population so that access is egalitarian.

Lessons from the bolivian covid-19 vaccine mandate

Diana Zeballos Rivas¹, Juan Aguilar Ticona¹, Doss-Gollin Simon², Marciglel Morais¹, Luis de Souza¹

¹Universidade Federal da Bahia Brazil, ²Boston Children's Hospital United States

Background: The study analyzed the Bolivian governments implementation of the COVID-19 vaccination card, which purports to increase vaccination rates and strengthen coverage with the entire vaccination schedule in the country. We aimed to describe the measures adopted, their effectiveness and impacts on adherence to the vaccine.

Methods: We conducted an exploratory study, based on the analysis of Supreme Decrees 4640 and 4641 of 2021, and secondary data from the Bolivian Ministry of Health and Our World in Data. The 7-day moving average of COVID-19 vaccination was calculated. We also estimated the difference of the cumulative vaccination rate between December 22, 2021, and January 19, 2022, referring to the dates of enactment and suspension of the decrees.

Results: The requirement of a vaccination card to enter public and governmental

spaces increased vaccination coverage by 9.6% for the first dose and 4.4% for the second dose. Resistance to the measure resulted in its postponement and, later, suspension after only 28 days of effectiveness, which was followed by a decrease in the 7-day moving average of COVID-19 vaccination. The short time span between the measures announcement and implementation left insufficient time to plan vaccine distribution and manage supply shortages. New vaccination centers were not created, and existing centers were overcrowded and often had to share their spaces with testing centers. Long queues fueled public discontent with the policy, which then was exploited by the anti-vaccine movement, responsible for spreading misinformation and contesting the measures.

Conclusion: The COVID-19 vaccination card had a positive impact on the vaccination rate, principally among the unvaccinated, however, it was not a long-term effect, because it was soon revoked. Management challenges and misinformation about the vaccines had a negative impact on adherence to the proposal and the lack of planning placed a heavy burden on the health system.

Psychosocial effects on the elderly, during the period of lockdown due to the COVID-19 pandemic, in a city in the interior of the state of São Paulo, Brazil, between 2020 and 2022

Mario Angelo Cenedesi Junior¹, Sílvia Vouillat²

¹Cenedesi Junior University of Business and Social Sciences (UCES) Brazil,

²University of Business and Social Sciences (UCES)

Background and Objectives: The lockdown caused by the COVID-19 pandemic brought about important changes in the daily lives of Brazilians, a fact that needs to be observed especially in the elderly, a portion that is in constant population growth. This confinement can trigger several psychosocial effects, such as feelings of loneliness, sadness, anxiety, among others, so that knowing them, in the elderly population, is understanding what is going on with their Mental Health and, thus, being able to reorganize the Health Services (through strategies and protocols) to provide the necessary support to patients.

Methods: This is a basic, observational and cross-sectional study with a descriptive objective and a mixed methodology. 253 elderly people were interviewed in a city in the interior of the state of So Paulo, Brazil, in the last quarter of 2022 - health professionals and people with severe mental disabilities were excluded from the study.

Results: 38.25% of the elderly surveyed are male and 61.73% are female. In relation to thinking that, during lockdown, the ability to identify their own emotions and those of others worsened, 19.13% answered yes; as for feeling sad for not being able to share time with their loved ones, 83.61% answered yes; in relation to feeling anxiety for not being able to predict what would happen, 77.6% answered yes; when asked if they suffered from loneliness, 66.3% answered yes.

Conclusion: The present study shows that a large part of the elderly population presented sadness, anxiety and/or loneliness during lockdown due to the COVID-19 pandemic, even surpassing the values mentioned by the World Health Organization (WHO), so that Public Politics in Mental Health need to be created (or expanded) to serve this portion of the population, improving their quality of life.

Safety and efficacy beliefs on covid-19 vaccination in perspective of the second booster dose administration: A survey experiment in the italian population

Dario Menicagli¹

¹IMT School Advanced Studies Lucca Via S.Agostino 66 Italy

Background and objective: During the Summer of 2022, many European countries started administering the fourth dose of COVID-19 vaccines upon developing an efficacious vaccine against the newly detected variants. However, despite governmental perspectives and previous findings reporting both actual and potential high acceptance rates on first-dose vaccination, more is needed to know about the diachronic evolution of the citizens engagement and how the change in perception of vaccine safety and efficacy affects vaccination intention. This study aims to investigate Italys fourth dose COVID-19 vaccination acceptance rates and how the differential presentation of positive-framed messages regarding the scientific evidence on the fourth dose safety and efficacy could influence citizen beliefs and responsiveness.

Methods: We designed a multi-scale survey to study retrospectively the evolution of the beliefs behind each decision to vaccinate in the different stages of the vaccination campaign (i.e., from the first up to the third booster dose) and individual trust in scientific and political institutions in each period of the vaccination campaign. Secondly, we implemented different message-framed vaccine safety and efficacy treatments to evaluate how they influence individual

intention to uptake the new dose.

Overall, theory-driven structural equation analysis will reveal what factors are significant predictors of the willingness to vaccinate in a balanced sample of 500 Italian participants.

Results: We show a distinct evolution of the perceived efficacy and safety during the vaccine campaign and the importance of message targeting this latter component to increase vaccination intention. Moreover, we investigate how trust in political and scientific institutions changes during a pandemic according to vaccine beliefs. Conclusion: Vaccination campaign could benefit from messages based on vaccination safety more than efficacy perception and needs to consider a dynamic evolution of these components during multiple vaccination stages and the role of trust in scientific institutions more than governmental ones.

Lessons learnt from the vaccination strategy against COVID-19 in Spain

Ana Fernandez-Dueñas¹, Carmen Olmedo¹, Aurora Limia¹, Laura Sanchez-Cambronero¹, Sonia Fernandez-Conde¹, Elena Cantero², Rocio Villa-Pizarro³

¹Immunization Programme Area, General Directorate of Public Health, Ministry of Health, Spain, ²Technical Assistance TRAGSATEC to the Ministry of Health of Spain, ³Servicio de Medicina Preventiva y Salud Pública - Hospital Clínico Universitario de Valladolid, Spain

Background and objective: Vaccination policy in Spain is characterised by the decentralisation of national health system. Regional departments of health are the vaccination programmes managers and the Ministry of health, coordinates and oversees. However, a single vaccination strategy against COVID-19 was developed. The objective is to describe the lessons learned from this process and the strategy. Methods: Structure, work and decision-making process of the working groups (WG) of the strategy were assessed: the multidisciplinary technical WG for the development of the strategy (which included the national immunization technical advisory group and experts from bioethics, sociology, pharmacovigilance, etc.), WGS on mathematical models, vaccine effectiveness and on the development of the COVID-19 registry. Additionally, results of a survey to the members of the technical WG.

Results: Recommendations from the technical WGs were not always implemented at political level.

Given the uncertainty of the pandemic, the strategy was continuously revised. Having a multidisciplinary team of independent experts and other useful tools for decision-making such as mathematical models, effectiveness studies was essential.

COVID-19 vaccination registry is the first single national vaccination registry developed in Spain. It has boosted regional information systems and enabled a real-time monitoring of the vaccination strategy implementation. Vaccination data from all residents was brought together in a homogeneous and standardized way. A lack of technical information suitable to the needs of the population was identified.

Conclusion: Having multidisciplinary WGs are necessary along with their independence in the decision-making process.

Mathematical models and effectiveness studies are valuable tools to revise and improve vaccination policies.

High quality information on vaccination implementation programmes is essential to monitor them. Strengthening information systems in public health is critical, notably their flexibility and interoperability.

It is necessary to incorporate providing technical communication to the population as an essential element in vaccination strategies.

Genomic surveillance of sars-cov-2 in tunisia : January 2021-december 2022

Mouna Safer¹, Wissal Kalai¹, Arwa Neffati¹, Aicha Hchaichi¹, Sonia Dhaouadi¹, Hajer Letaief¹, Fatma Youssef¹, Emna Mziou², Souha Bougatef², Leila Bouabid², Sondes Derouiche², Nissaf Alaya², Ilhem Boutiba¹, Henda Triki³, Hela Karray⁴, Tunisia MASTOURI⁵

¹Observatory of New and Emerging Diseases Tunis Tunisia, ²Charles Nicolle Hospital, Tunis Tunisia, ³Pasteur Institute, Tunis Tunisia, ⁴Habib Bourguiba Hospital Sfax TUNISIA, ⁵Fattouma Bourguiba Hospital Monastir Tunisia

Background and objective: Since emergent Variant Of Concern (VOC) has threatened public health and has impacted vaccination effectiveness, genomic surveillance of these variants was becoming a crucial approach allowing to monitor the evolution of SARS-CoV-2 variants and to guide COVID-19 pandemic response.

The objective of this study was to describe the genomic epidemiology from January 2021 to December 2022.

Methods: Sequences were performed on nasopharyngeal specimens With CT less than 25 tested in all Tunisian laboratories of clinical virology. The sample selection strategy was conducted in accordance with the Tunisian sequencing strategy of SARS-CoV-2 based on two approaches : First, on a weekly randomly stratified sample by gouvernorate and second on a targeted sampling focusing on specific subsets: imported cases, vaccinated cases, reinfections, severe cases... SARS-CoV-2 genome sequencing methods applied during this study were: whole-genome sequencing (wgs), partial s gene sequencing and variant-specific real-time rt-pcr tests. clinical virology laboratories involved were : Charles Nicolle hospital, Tunis ; Pasteur Institute ; Habib Bourguiba hospital Sfax and Fatouma Bourguiba hospital, Monastir.

Results: During this study a total of 5999 nasopharyngeal samples have been sent to laboratories of clinical virology. Using the three sequencing methods a total of 4937(82.3%) lineages were assigned and 4105(83.15%) were classified as VOC : 1442 Omicron(35.2%) ; 1418 Delta(34.6%) ; 1230 Alpha(30%) ; 7 Beta(0.2%) ; 1 Alpha and 1 coinfection Delta omicron.

Periods of predominance of VOC were identified as following : Alpha variant was predominant from ISO week3/2021 to ISO week 25/2021 ; Delta variant from ISO week 26/2021 to ISO week 50/2021 and Omicron from ISO week 1/2022.

Conclusion: This study was the first Tunisian national analysis of main lineages of SARS-CoV-2 circulating during two years . This Epidemiological genomic surveillance of SARS CoV 2 have contributed to implement preventive measures in a timely manner.

Ethical justifications for the need for pandemic preparedness from sars to SARS-CoV-2: a scoping review

Rocio Villa-Pizarro¹, Miguel Ángel Royo Bordonada², Fernando José García López², Marife Muñoz Moreno⁴, María Pilar Arnáiz Ibañez⁵, Natalia Madueño Moreno⁶

¹Servicio de Medicina Preventiva y Salud Pública - Hospital Clínico Universitario de Valladolid Spain, ²Escuela Nacional de Sanidad (Instituto de Salud Carlos III), ³Centro Nacional de Epidemiología, Instituto de Salud Carlos III Spain, ⁴Unidad de Investigación Biomédica (iBc), Hospital Clínico Universitario de Valladolid, Spain, ⁵Hospital Clínico Universitario Natalia, ⁶Instituto de Psiquiatría y Salud Mental, Hospital Gregorio Marañón Spain

Background and objective: The 21st century has seen numerous epidemics with pandemic potential, and during these years literature has been published urging competent authorities to prepare regions for a future pandemic. However, the crisis caused by SARS-CoV-2 has been devastating and marked by improvisation. We ask what part of this literature clarified the ethical justifications for choosing to prepare and what arguments were present in it.

The objective of this overview review is to describe the ethical justifications for pandemic preparedness proposed in the period between 2004 and 2020.

Methods: Any type of literature published between 2004 and 2019 in whose title or abstract the ethical justification for pandemic preparedness is described as the main topic was included. The sources of information searched were PubMed and Cochrane. The literature available in full text was examined for eligibility. Finally, data (curation) was extracted.

Results: From an initial identification of 120 articles, 13 were finally included for analysis. That is, although some texts deal with the ethical obligation to be prepared for a pandemic, these are scarce and rarely develop this ethical justification beyond how this preparation should be fulfilled. Ethical guidance is even presented in an instrumental manner (as a way to improve citizen collaboration), without going into the discernment (principles, assumptions...) that underpins these moral proposals.

Conclusion: The disparity between the insurances of the last 15 years before the SARS-CoV-2 pandemic and the response capacity and preparedness that were available at the beginning of the crisis is an area for improvement in risk communication. Moreover further reflection on the ethical justifications could help authorities and society as a whole to focus their efforts, during this inter-pandemic period, on preparing for future pandemics. A need to involve the population in preparedness and to make decisions in a transparent manner was shown.

The impact of the COVID-19 pandemic on mental health in South Korea

Eun-Whan Gyeonggi¹

¹Research Institute Korea, Republic Of Eun-Whan Lee Gyeonggi Research Institute Korea, Republic Of

Objective: This study was conducted to find out the impact of the COVID-19 pandemic on mental health in South Korea.

Method: We surveyed 2,000 people across the country in South Korea. To assess the severity of mental health, this study used the Generalized Anxiety Disorder 7-items (GAD-7) and Patient Health Questionnaire-9 (PHQ-9) scale and so on.

Result: 55.8% of the people were experiencing feeling depressed, and 30.6% of the people suffering from sleep disorders due to the COVID-19 pandemic. As measured by the PHQ-9 scale, a clinical depressive symptom screening tool for mental health, the risk group for depression that required psychiatric treatment was 17.6%, and the generalized anxiety disorder (GAD-7) reached 31.9%. In particular, there were differences in depressive symptoms and generalized anxiety disorder depending on the individuals income level. In the case of the prevalence of severe depressive symptoms, the lowest and highest income groups were 5.2% and 1.9%, respectively, and the difference reached about three times. In addition, the prevalence of severe anxiety disorder were 8.6% and 4.4% in the lowest and highest income groups, respectively, and the difference reached about twice.

Conclusion: This study confirmed the negative impact of COVID-19 on mental health. In particular, it was revealed that the negative impact of COVID-19 on mental health differs depending on the individuals socioeconomic level.

Preventing pandemics: the vital role of the law. Strengthening countries' legal preparedness for public health emergencies

Martha Achan¹, Gian Burci², Sam Halabi³, Emem Udoh⁴, Maria Campisi⁵, Maria Campisi⁵, Sam Halabi⁶, Cédric Apercé⁷

¹Infectious Diseases Institute, Uganda, ²Graduate Institute of International and Development Studies, Geneva, Switzerland, ³O'Neill Institute for National and Global Health Law, Georgetown University, United States, ⁴Resolve to Save Lives, Nigeria, ⁵International Development Law Organization, Italy, ⁶Global Health Security Agenda (GHSA) - Legal Preparedness Action Package (LPAP), O'Neill Institute for National and Global Health Law, Georgetown University, USA, United States, ⁷Resolve to Save Lives, United States

Outline

While the world is watching WHO Member States revising the global health security architecture in Geneva, research shows that one of the main bottlenecks to the COVID-19 response was the lack of public health emergency (PHE) preparedness at country level (Source: Report of the Independent Panel for Pandemic Preparedness and Response, 2021). COVID-19 has dramatically illustrated the gaps and weaknesses of national legislation and systems in effectively preventing and responding to the pandemic. The law has a vital role to play in strengthening countries' preparedness and in advancing global health security. Effective national legal and policy frameworks that comply with international norms and standards are key components of a comprehensive system that enables countries to promptly and efficiently prevent and manage public health threats. Legal barriers, however, can hinder countries' capacity to respond rapidly and effectively to an emergency, including by hampering effective and equal access to protective measures and medical countermeasures, delaying decision making processes, and undermining the legitimacy of response measures.

PHE Legal Preparedness is a core competency that enables a country to effectively use the law to plan for and implement strategies to prepare for, prevent and respond to PHEs. Despite this, Legal Preparedness has not received much attention as a critical capacity for PHE preparedness and many countries still lack local capacities that can support governments in strengthening and mobilizing their legal frameworks in line with international guidance.

Objective: This workshop will raise participants' awareness about the concept of Legal Preparedness and discuss the role of the law in advancing PHE preparedness and response. It will discuss the importance of Legal Preparedness as a critical capacity for PHE prevention and preparedness. The workshop will be delivered as a dialogue among panelists, and will be aimed at non-legal public health practitioners. It will provide an overview of the concept of Legal Preparedness and its role in PHE prevention and response, discuss the need for capacity building on legal preparedness and present experience and best practices from LMICs. By facilitating a dialogue between national and international experts, it will present lessons learned from the COVID-19 pandemic and other past emergencies to identify gaps, needs and opportunities to strengthen countries' capacities to enhance PHE legal preparedness.

Key Questions

The workshop will address the following key questions:

What is legal preparedness for PHEs? What legal challenges and barriers have been recognized during the COVID-19 pandemic and other public health emergencies? How can the law enhance countries' preparedness to prevent, detect and respond to PHEs? What is the process by which countries can assess and improve their legal preparedness?

What capacities are needed, and which tools are available, to enhance legal preparedness at country level?

Could humanity build a new planetary governance system able to tackle pandemics and other existential threats? a thought experiment

Alejandro Jadad¹, Francesca Zanni², Iveta Nagyova³, Jean-Marie Okwo-Bele⁴, Jeff Smith⁵, Luís De Souza⁶, María Sáenz Madrigal⁷, Costa Gualtieri (Walter)⁸

¹Centre for Digital Therapeutics (Toronto, Canada), Canada, ²University of Bologna, Italy, ³Department of Social and Behavioural Medicine, Faculty of Medicine, PJ Safarik University, Kosice, Slovak Republic, ⁴World Federation of Public Health Associations (WFPHA), Independent, Switzerland, ⁵Australian Centre for Climate and Environmental Law, NA, Australia, ⁶World Federation of Public Health Associations (WFPHA), Federal University of Bahia (Brazil), Brazil, ⁷Health Equity Network of the Americas (HENA), ⁸Ricciardi, Università Cattolica del Sacro Cuore, Italy

Thought experiments are mental exercises in which human imagination is used to put a hypothesis or idea to the test without actually conducting an experiment or research project.

From February to November 2022, we sought to answer the following question: "If we had the power to add just one resource to what was available the day COVID-19 was declared a pandemic, so that we could change its course for the better, which resource would we choose?"

Soon, we concluded that the key missing piece was a species-wide, representative, accountable and empowered governance system. In light of this, the one imaginary resource we chose to add was a Planetary Health Protection Council (PHPC). This would be a body that would convene leaders from the government and the corporate, academic and civil society sectors with the goal of developing trustworthy measures that would allow humans to interrupt the spread of a pandemic, or curb other existential threats.

Given that the success of the PHPC would depend on being perceived as trustworthy by the general public, it could be complemented with two independent related structures, which could be spearheaded and coordinated by the public health community: A platform to facilitate equitable, transparent and inclusive participation by representative samples of the world's population, and a system of in-person and virtual tools designed to encourage community engagement around controversial issues during the pandemic, from villages to the entire globe. Workshop participants will be invited to join the ongoing reflections around the proposed governance system, and to identify the optimal contributions of the public health community to prepare the world for the next pandemic or for other existential threats.

During the workshop, participants will have the opportunity to explore:

The feasibility of a new planetary governance system able to tackle pandemics and other existential threats. The optimal role of the public health community to open spaces for discussions, reflections and initiatives related to the emergence of a new species-wide, representative, accountable and empowered governance system. The contributions of thought experiments as tools for public health leaders to confront difficult questions, mostly in relation to complex ethical issues or policy decisions.

By the end of the workshop, participants would have contributed to answering the following key questions:

What structure and working mechanisms would constitute a system of governance that is species-wide, representative, trustworthy, accountable and empowered to tackle the next pandemic or other major existential threats? How could public health leaders and the public health community at large become more effective at engaging the population they serve, as well as leaders of the government, corporate, academic and civil society sectors while facing the next pandemic or other major existential threats? What contributions could thought experiments play as tools for public health leaders to confront difficult questions?

Pandemic Preparedness and Response in the post-COVID-19 era: Governance and PHSMs

Yanping Zhang¹, Chao Ma², Yi Cai³, Zijian Feng⁴, Xiaofeng Liang⁵
¹China CDC, Division of Infectious Diseases, China, ²Evidence-Based Vaccine Policy Research Office, Chinese Center for Disease Control and Prevention, China, ³School of Public Health, Wuhan University, China, ⁴Chinese Preventive Medicine Association; Asia-Pacific Regional Liaison Office, WFPHA; China Association for Science and Technology UN Consultative Committee on Life Science and Human Health (CCLH), China, ⁵Chinese Preventive Medicine Association; Disease Control and Prevention Institute of Jinan University; China Association for Science and Technology UN Consultative Committee on Life Science and Human Health (CCLH); WFPHA, China

In this workshop we will review the experiences and lessons learnt in the fight against COVID-19 in China for the purpose of better preparing for and responding to future pandemics, from the following perspectives:

Taking a whole-of-government and a whole-of-society approach for the governance of COVID-19 pandemic is a key of success in the early phase of rapid containment. Immediately after the outbreak is reported, the Chinese government established a multi-sectoral joint response mechanism, consisting of 32 ministries, under the overall leadership of State Council. The national office for joint response mechanism oversees the epidemic situation and response actions, and over 4 million of community workers from 600,000 neighborhood committees in urban/rural areas were all mobilized for the implementation of public health and social measures (PHSMs) and the provision of logistic services during lockdown. Those approaches above have served as the fundamental basis for the successful elimination of COVID-19 outbreaks for a long period in China.

The technical tools including massive testing, contact tracing using digital tools, and lockdown are key prerequisites for 'Zero-COVID' policy in China. Massive testing is necessary to rapidly screen the infected persons and put them under isolation so as to prevent further transmission. China has established sufficient PCR testing capacity. Digital tools and apps using big data technique are the enabler for timely epidemiological investigation and contact tracing to identify potential sources of infection and close contacts for quarantine, which attributed to the close collaboration between the public health sector, information technology sector, and the public security sector. Strict lockdown of high-risk areas is a useful tool to ensure the cut-off of the transmission at community level, while the basic services and logistic support are challenging and needs to be well arranged.

The status and challenges of mass vaccination program in China. China was the first country to launch the COVID-19 vaccination campaign and has made positive progress in the fight against the COVID-19, with a complete vaccination rate of over 90% for the entire population. Details of COVID-19 mass vaccination campaign and practical challenges will be introduced in this workshop.

Specific aims/objectives and component parts

To provide an overview on China's collaborative governance mechanism and cross-sectoral cooperation approaches in response to COVID-19 pandemic;

To demonstrate how technology plays a key role in mass testing, contact tracing, and lockdown through the experiences sharing;

To share the practices how China pushed forward with the mass vaccination program and implemented public health and social measures by engaging and integrating community resources.

Key questions that the dialogue will address

What is the structure and mechanism of the WGA collaborative governance in China? What is the key of success in the early phase of rapid containment?

How the use of technology enables China's dynamic Zero-COVID policy? What challenges have been encountered in the implementation and how have they been effectively addressed?

What are the challenges of COVID-19 vaccination in China and how we address those challenges in the preparedness for next pandemic?

Research use cases measuring the impact of COVID-19 on population health feeding into a federated research infrastructure

Martin Thißen¹, Juan Gonzalez-Garcia², Francisco Estupiñán-Romero³, Petronille Bogaert⁴, Enrique Bernal-Delgado⁵, Population Health Information Research Infrastructure (PHIRI)⁶

¹Robert Koch Institute (RKI) Germany, ²Institute for Health Sciences in Aragon, Spain, ³Institute for Health Sciences in Aragon (IACS), Spain,

⁴Sciensano, ⁵Institute for Health Sciences in Aragon (IACS) Spain,

⁶Sciensano Belgium

Outline: The COVID-19 pandemic has clearly demonstrated the urgent need for a cross-border and structured European mechanism to exchange, organize and access reliable health information between countries, especially in the area

of population health. Population health information, defined by data on health status, health determinants and healthcare systems performance, allows for oriented research to increase the knowledge base in Europe and underpin political decision-making. Its exchange requires timely and topical provision of high-quality health information. There are many indirect effects of the COVID-19 pandemic that affect health through various pathways including secondary consequences on health and wellbeing due to delayed prevention, diagnosis and medical treatment. Within the Population Health Information Research Infrastructure (PHIRI) project we measured the impact of COVID-19 on population health through four research use cases demonstrating how a broad variety of routine data can be pooled and/or used for secondary analysis in a distributed way across Europe aiming to facilitate research by making scalable, reproducible methods available. These real-life use cases represent pilot activities for the benefits and added value of an infrastructure supporting federated analysis by bringing together data from different European countries. In over 20 data contributing countries data is mobilized and analyzed in a distributed manner. The use case outputs will be processed in an interoperable way by formalising data models, data management processes and analytical pipelines, all of which are part of the client-server PHIRI federated infrastructure on population health science implemented as here 10.5281/zenodo.6483177 [1]. Aims and component parts: This workshop aims to ensure a better understanding of COVID-19 impacts in specific subgroups and risk settings by conducting research through use cases of immediate relevance to provide actionable outcomes to guide policy makers in preparedness and response scenarios. We will provide insight into the backbone of the analyses, the PHIRI federated research infrastructure (FRI) achievements, in which the governance step-wise approach and the technological solutions will be described. Finally, we will touch ground on the future developments, in particular, the interaction of the PHIRI infrastructure with existing European-wide initiatives like the European Health Data Space for secondary use (EHDS2). Knowledge and capacity developed across Europe is shared in this workshop. The three presentations will focus on selected aspects of COVID-19 impacts on population health as well as the development and implementation of the PHIRI federated approach. The first presentation will be on the FAIRified use cases analysis results focusing on comparisons between countries. This will be followed by a presentation on what the PHIRI FRI has achieved so far. The third presentation looks at the interlinkages and an enhanced version of a fully operative PHIRI infrastructure improving the analytical services. Exchange with the audience will facilitate knowledge and opinion exchange through an interactive Mentimeter poll during the session. Key questions: 1) What are the impacts of COVID-19 in specific subgroups and risk settings compared across European countries? 2) What do population health researchers' need to enhance their research when reusing individual sensitive data and how PHIRI FRI can help? Links: [1] <https://zenodo.org/record/6483177>

Global coordinated surveillance of human pathogens for public health responses to new, emerging, and re-emerging epidemics

Eric Arts¹, Elena Pariani², Miguel Quinones-Mateu³, Christopher DeGroot¹, Eric Arts¹, Elena Pariani⁴

¹Western University 1151 Richmond St., London, ON, Canada, N6A 3K7 Canada, ²Department of Biomedical Sciences for Health, University of Milan, Italy, ³University of Otago, Dunedin, New Zealand, ⁴University of Milan Department of Biomedical Sciences for Health Via Carlo Pascal, 36 - 20133, Milan, Italy

Background and key objectives

Early in the pandemic, researchers in Lombardy, Italy pioneered the measure of SARS-CoV-2 load in wastewater (WW) as a strong correlate of SARS-CoV-2 case loads within the Lombardy region/population, a WW surveillance program that continued to present day. Starting in late 2020, the province of Ontario in Canada also established a comprehensive program to monitor SARS-CoV-2 in WW representing a population of 11 million (of 14 million in Ontario), similar in population size to Lombardy but across a sampled area the size of Italy. Ontario added next generation sequencing to the WW program to identify and monitor of the spread of specific SARS-CoV-2 variants of concern. During the pandemic, Public Health units in both Italy and Canada relied on individual case testing to determine SARS-CoV-2 load and variant type but this all changed in Ontario with the Omicron wave. In January 2022, to save costs, Ontario cancelled nearly all individual, PCR-based SARS-CoV-2 testing and switched to population-based monitoring of estimated SARS-CoV-2 case loads from the WW surveillance data. However, despite immediate data availability, estimated SARS-CoV-2 case loads from WW was slowly adopted by public health for SARS-CoV-2 prevention

initiatives. For this workshop the first key objective is to determine how to remove barriers in using these alternative surveillance tools by Public Health professionals to respond to regional epidemics. As the pandemic progressed around the world, more countries established SARS-CoV-2 WW surveillance programs. However, there is little coordination between Public Health agencies around the world or by the World Health Organization (WHO) to share WW surveillance data which would inform recommendations for prevention and strategic distribution of vaccines in specific regions. Furthermore, the current WW surveillance is heavily reliant on well-maintained wastewater systems, often absent in low-income settings. Starting in June 2021, an international consortium piloted a WW surveillance program in Medellín–Columbia, Caracas–Venezuela, Ibadan–Nigeria, Kampala–Uganda, and Suva–Fiji using WW from open drainage systems in slum districts. An interdisciplinary team of health geographers, virologists, epidemiologists, and engineers are developing tools to monitor the load and type of pathogens in these low-income settings. For the second objective we will explore the feasibility, effectiveness, and cost to establish a global, coordinated WW surveillance program to monitor for new and re-emerging pandemics to help public health reduce or prevent the next global pandemic. The third objective will involve a discussion of pros and cons of using individual case testing compared to using WW and environmental sampling for pathogen surveillance. AGENDA Workshop will involve an open discussion to provide valuable insights into a working document to present as a future program to the WHO.

Popul. Med. 2023;5(Supplement):A551

Interventions to fight against covid-19 in different countries: Challenges and lessons learned

Henrique Barros¹, Thais Aranha-Rossi², James Macinko¹, Arnaud Simeon³, Ines Dourado⁴

¹University of Porto University of Porto Portugal, ²State University of Bahia, Brazil, ³Université Lumière Lyon 2 Université Lumière Lyon 2 France, ⁴Federal University of Bahia Federal University of Bahia Brazil

Brief Outline Of The Overall Workshop

This workshop proposition aims to address interventions to fight against COVID-19 focusing on Primary Health Care (PHC) services and surveillance strategies in countries with different responses as a possibility to systematize learning for future pandemics. Non-governmental responses will also be discussed. Portugal's response to COVID-19 is considered successful by the adoption of different surveillance strategies, and multiple actions in its health system. In the United States and Brazil, countries with different health systems, high numbers of cases and deaths were observed due to COVID-19. In coping with these scenarios, we highlight the importance of strengthening health systems, expanding testing, and surveillance actions, integrating the healthcare network, and wide vaccination coverage.

Specific Objectives And Component Parts

The specific objectives of this workshop are: (1) To present interventions to fight against COVID-19 focusing on primary care services and surveillance strategies in countries with different responses as a possibility to systematize learning for future pandemics, and (2) To discuss the role of Primary Health Care in the COVID-19 pandemic. This workshop will address pandemic response interventions, especially actions in primary care, expansion of testing, and surveillance strategies. The main pillars on which the Portuguese response and the lessons learned were structured will be presented. Intervention in France will be also discussed. The role of primary care in the response to COVID-19 will be presented as a contribution to thinking about future scenarios in different countries. A research intervention that aimed to expand testing, isolation, quarantine, and telemonitoring (TQT-COVID-19) in primary care units in two Brazilian capitals will also be systematized. From these experiences, we seek to bring contributions to understanding the different answers and thinking about coping with future problems.

The Key Questions That The Workshop Will Address

* What are the main components of interventions and/or responses to fight against the COVID-19 pandemic?

* What is the role of Primary Health Care in the COVID-19 pandemic?

* What are the main lessons for future pandemics?

Popul. Med. 2023;5(Supplement):A552

DOI: 10.18332/popmed/164714

Simulation exercises to enhance public health pandemic/epidemic preparedness

Emanuela Frisicale¹, Maria Dente², Francesco Maraglini³, Anna Palamara⁴

¹Italian Ministry of Health General directorate of health prevention, Ministry of Health Italy, ²National Institute of Health, National Center for Global

Health, Italy, ³Italian Ministry of Health Head of office Prevention of communicable diseases and international prophylaxis, general directorate of health prevention Italy, ⁴National Institute of Health Director, infectious disease department, National Institute of Health Italy

The COVID-19 pandemic revealed weaknesses in healthcare systems globally, above all in the detection, preparedness and response to biological threats such as emerging pathogens. The pandemic was not completely unexpected, considering for example how in 2018 WHO included "Pathogen X" among the list of pathogens which could threaten global health security and have a pandemic potential. In a simulation exercise (SIMEX) there are three principle phases: * A PRE-EXERCISE PHASE dedicated to planning, logistics, implementation of exercise materials and recruitment of participants; * AN EXERCISE IMPLEMENTATION PHASE, which includes the preparation of the facilitators, the beginning of the exercise, its conduct, the "hot" debriefing with the participants and the closure of the exercise itself; and finally * A POST-EXERCISE PHASE dedicated to the collection of results, the debriefing with the facilitators, the preparation of a report and evaluation of the exercise and the administrative reporting. This workshop will present epidemic and pandemic preparedness from an international perspective through the experience of two international experts of the European Centre for Disease Prevention and Control and the example of pandemic simulations carried out currently as part of the National strategic and operational plan for preparedness and response to an influenza pandemic (PanFlu) 2021-2023, in Italy. The Congress takes place in a time of change in the global health security governance context with the revision of the International Health Regulations, the discussions around the Pandemic Treaty and, in the European Union, with the issue of the recent regulation EU 2022/2371 of the European Parliament and of the Council on serious cross-border threats to health. In addition, at the time in which the workshop will take place, the European Centre for Disease Prevention and Control will have a newly expanded mandate and Italy will have performed and analysed one of two national simulation exercises on a single scenario that will take place during 2023 to test the implementation of above-mentioned plan. The changing pandemic preparedness context, with specific reference to simulation exercises and their role in supporting effective and resilient health care systems during epidemics and pandemics, will thus also be discussed.

Specific aims/objectives and component parts

The workshop aims at promoting discussion among experts about the role and impact of simulation exercises for pandemic preparedness. The specific objectives are to share experiences in SIMEX implementation, discuss how to build national capacity in this field and deepen knowledge on the potential development of SIMEXs taking into account COVID-19 pandemic lessons learnt. The workshop will take place at a time in which the results of the first Italian SIMEX will be available, and Ministry of Health and the National Health Institute could be able to contribute to the debate also sharing preliminary results.

The key questions that the workshop will address

* The role of simulation exercises within the emerging global health governance landscape * Are States aware about the potential of SIMEXs in improving preparedness and readiness to emergencies? * Can SIMEX be effective in helping during an emergency? * How could SIMEX evolve in light of the COVID-19 pandemic legacy?

Popul. Med. 2023;5(Supplement):A553

DOI: 10.18332/popmed/164585

From national to international health policy making: Lessons learned from ASPHER's covid-19 task force

Alison McCullum¹, Nadav Davidovitch², John Middleton¹, Nadav Davidovitch³

¹ASPHER United Kingdom, ²Ben-Gurion University, Israel, ³BGU and ASPHER Israel

* brief outline * ASPHER, (Association of Public Health Schools in the WHO European Region), convened a COVID-19 Task Force (TF) in early 2020. TF has involved over 60 experts, 30 member schools, more than 20 countries across four continents, supported by young professionals (YPs). The COVID-19 TF became a unique expert forum for mutual support, sharing, reviewing, and presenting evidence on epidemiological, technical, societal, and political dimensions of the COVID-19 pandemic across Europe. Working with European and national health authorities and non-governmental organisations (NGOs), it prompted and supported the coordination of policy responses across WHO European Region.

* Drawing on members' collective knowledge and expertise, the TF produced a significant body of work on different public health aspects of the pandemic and gaps in responses. Since its inception, the TF has produced more than 30 peer-reviewed publications, regular position statements, reports on topics from personal to planetary protection including: face masks, testing, tracking, vaccination, health inequalities, safe schools, advocacy for wider social protection and global

vaccine equity. * This workshop will reflect on how to set-up, build, scale-up, and sustain collaborations with wide geographic, cultural, linguistic, and political-administrative coverage to support the capacity and preparedness of public health institutions during future challenges in the context of strengthening global health response. * specific objectives * The panel will explore key lessons from ASPHER's COVID-19 Task Force: fostering independence, interdisciplinarity, and trust; a flexible, bottom-up organisation; and involving young professionals. It will consider what should be replicated, scaled up, improved, and reshaped to improve preparedness and response to other public health challenges, including future pandemics. * Key questions* The panel will explore how to set up collaborations across cultural and political-administrative boundaries to strengthen the advisory capacity of public health institutions during future challenges with a strong focus on international collaboration and the need to move from national to international / global health perspectives.

* The panel will reflect on three key lessons. First, effective cross-country comparative work was made possible by the group's independence, interdisciplinarity, and high trust between members. These characteristics enabled unencumbered rapid sharing of ideas, utilisation of data, insights in local languages, and access to the front-line experience of members, those in health authorities or advising national or regional governments. Shifting perspective from national to international perspective will be emphasized, with vaccination policies, TRIPS waivers and addressing inequities as examples.

* Lesson 2 is the importance of a flexible, bottom-up organisation, enabling members to pursue individual research, education, and advocacy agendas while acting in concert. The TF strengthened and deepened collaborations between ASPHER Schools of Public Health.

* Lesson three combines policy advocacy, shaping public health education and providing training opportunities. YPs' expertise has been critical, preparing weekly situation reports, horizon scanning exercises, surveys of ASPHER members, and contributing an early-career perspective to the groups' outputs. These opportunities in knowledge transfer and leadership should be replicated as we tackle wider public health challenges including climate change, austerity and war.

Evaluation methods applied to digital health interventions: What is being used beyond randomised controlled trials? A scoping review

Robert Hrynyschyn^{1,4}, Christina Prediger¹, Christiane Stock^{1,2}, Stefanie Maria Helmer^{3,4}

¹Institute of Health and Nursing Science, Charité–Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany, ²Unit for Health Promotion Research, University of Southern Denmark, Esbjerg, Denmark, ³Human and Health Sciences, University of Bremen, Bremen, Germany, ⁴Leibniz ScienceCampus Digital Public Health Bremen, Bremen, Germany

Background and Objective: Digital health interventions (DHI) can deliver health interventions with lower barriers to a wide audience and support behaviour change. Despite the potential of DHIs, evaluating their effectiveness is challenging. DHIs are often designed as complex interventions, and established evaluation methods, e. g., randomised controlled trials (RCT), have limited applicability for evaluating complex interventions. In this context, alternative evaluation methods are often discussed. Therefore, a scoping review was conducted to provide an overview of existing evaluation methods of DHIs beyond RCTs.

Methods: The Cochrane Central Register of Controlled Trials, MEDLINE, Web of Science, and EMBASE were screened in May 2021 to identify relevant publications. Studies were included that were (1) applying alternative evaluation Methods, (2) testing and reporting effects of interventions, and (3) dealing with DHIs. Inclusion was not restricted to any specific population or to specific contexts in which studies were conducted.

Results: Eight studies were identified, which included four alternative assessment designs. The most used evaluation design for DHIs were factorial designs (n=5), followed by stepped-wedge designs (n=1), sequential multiple assignment randomised trials (SMARTs) (n=1), and micro randomised trials (MRTs) (n=1). Some of these methods enable the adaptation of interventions (e. g., SMARTs or MRTs) and the evaluation of specific components of interventions (e. g., factorial designs).

Conclusions: Alternative study designs are appropriate for addressing some specific needs in the evaluation of DHIs. Alternative study designs might be beneficial in overcoming the current evaluation challenges in DHIs. However, it remains unclear how to establish these alternative evaluation designs in research practice and how to deal with the limitations of the designs.

Marketing in the metaverse, noncommunicable diseases and human rights

Andres Constantin¹, Maia Daniel²

¹O'Neill Institute for National and Global Health Law, Georgetown University, Washington, United States, ²Center of Technology and Society (CETyS), Universidad de San Andres, Argentina

The metaverse will change the world in many ways. Essentially creating virtual spaces owned by private companies where individuals, corporations, and even governments can interact with minimal oversight. Although the Web 2.0 had already offered a brand-new way of interacting with others, the interactions that the metaverse's immersive technologies enable will bring about a new worldview and multiple challenges. The metaverse will definitely offer numerous benefits for users—such as organizing virtual field trips for students or getting a telemedicine consultation with a doctor in any part of the world. However, the use of these technologies could also entail potential serious risks for the right to health and health-related rights. In this study we examine the legal and policy implications of marketing and advertising by unhealthy commodities companies (tobacco, alcohol, ultraprocessed foods/beverages) in the metaverse and what it means for people's health. In particular, we aim to answer questions, such as: what is or should be the role of public health authorities in the metaverse? Are current health-related legal standards applicable in the metaverse? Do we need specific norms to protect the right to health? What are the anticipated health and human rights risks that a poorly regulated metaverse—or poorly enforced laws and regulations in this space—can facilitate?

DOI: 10.18332/popmed/164849

The effectiveness of telemedicine interventions, delivered exclusively during the postnatal period, on postpartum depression in mothers without history or existing mental disorders: a systematic review and meta-analysis

Nivine Hanach¹, Nanne Vries², Hadia Radwan^{3,4}, Nour Bissani⁵

¹Department of Health Promotion, Maastricht University, The Netherlands,

²Department of Health Promotion, Maastricht University, Netherlands,

³Department of Clinical Nutrition and Dietetics, College of Health Sciences, University of Sharjah, Sharjah, United Arab Emirates, ⁴Research Institute of Medical and Health Sciences (RIMHS), University of Sharjah, Sharjah, United Arab Emirates, ⁵Department of Nutrition and Food Science, Faculty of Agricultural and Food Sciences, American University of Beirut, Beirut, Lebanon

Background and Objective: Postpartum depression, one of the most common forms of depression, is highly prevalent worldwide among women during childbirth. Despite available treatments for postpartum depression, numerous barriers hinder women to access care including time, financial constraints, and childcare concerns. Telemedicine interventions are suggested to be feasible to prevent and improve postpartum depression. The study Objective is to examine the effectiveness of telemedicine interventions -delivered exclusively during the postnatal period, on postpartum depression symptomatology in women with no history of mental disorders. Design: A systematic review and meta-analysis of randomized controlled trials.

Methods: PubMed, Web of Science, Cochrane Library, and ProQuest Dissertations and Theses databases were used to identify relevant randomized controlled trials, until 7 January 2020. Studies were quality assessed using the Cochrane Library Risk of Bias Tool. The Results of postpartum depression scores were pooled using a random-effects model. Intervention completion rate and participants' satisfaction were reported in a narrative form, as secondary outcomes.

Results: Ten trials including a total of 2366 participants, contributed data to the review. Seven studies were included in the quantitative synthesis. Women who received technology-based interventions, regardless of the type (web-based versus telephone-based), had a statistically significant improvement in postpartum depression (mean difference: -1.81, 95% CI: -2.68 to -0.93; P < .0001). The completion rate was 80% in the intervention groups compared to 76% in the control groups. Three studies reporting participants' satisfaction revealed that the participants were highly satisfied with the technology-based interventions.

Conclusions: Overall, telemedicine interventions appear to be promising in preventing and improving postpartum depression. Further larger-scale high-quality research is required to establish an evidence-based telemedicine approach, in terms of structure, content, and providers. Future economic evaluation is also vital to evaluate the long-term use of telemedicine in improving postpartum depression.

DOI: 10.18332/popmed/164905

The ethics of point of care devices and the need for AI policy frameworks in resources limited settings

Mimmie Watts¹, Ismaila Imahi², Tesfay Gebrehiwet³, Maha Gmira⁴, Wendy Cross⁵, Ian Rouse⁵

¹Policy Committee World Federation of Public Health Associations (WFPHA), Institute of Health and Wellbeing, Federation University Australia, Victoria, Australia, ²University of Energy and Natural Resources, Sunyani, Ghana, ³School of Public Health, College of Health Sciences, Mekelle University, Ethiopia, ⁴School of Digital Engineering and Artificial Intelligence, Euromed University of Fez, Morocco, ⁵Federation University Australia, Institute of Health and Wellbeing, Australia

Access to quality healthcare is a fundamental human right and one of the Sustainable Development Goals (SDGs), as adopted by the United Nations in 2015. Thus, so is the maintenance of high ethical standards in providing healthcare. An important requirement for healthcare practitioners is the practice of the concept of avoiding harm while doing good. Advances in technology, global industrialization, and more recently Artificial Intelligence (AI) have undoubtedly led to significant improvements and advances in healthcare delivery, including the Introduction of Point-Of-Care Testing (POCT) devices that can instantly provide data about measures of a patient's health. Unfortunately, these advances have inadvertently affected the ethical standards in the field and there are calls for appropriate structures to ensure that all healthcare beneficiaries, especially the vulnerable ones in society continue to enjoy high ethical standards expected in receiving healthcare. This article drawing on the TAM and UTAUT theories, provides comprehensive analysis on the need to develop policy and ethical framework for AI technologies in healthcare. We believe that this has great potential to accelerate scientific discovery in medicine and to improve health care services. Keywords: e-health, ethical policy, artificial intelligence, healthcare records, vulnerable groups, minority rights, mobile technologies, health equity

Factors affecting successful post-discharge engagement of emergency department patients with opioid use history who received telehealth recovery coaching services

Dennis Watson¹, Peter Phalen², Spencer Medcalf³, Sarah Messmer⁴, Alan McGuire⁵

¹Chestnut Health Systems, Chicago, United States, ²University of Maryland School of Medicine, Baltimore, United States, ³Indiana University Health, Indianapolis, United States, ⁴University of Illinois at Chicago, Chicago, United States, ⁵Indiana University-Purdue University Indianapolis, Indianapolis, United States

Background and Objectives: In recent years, emergency departments across the United States have implemented peer recovery coach (PRC) services to support patients who use opioids. The majority of such interventions discussed in the literature follow an in-person modality where PRCs engage patients directly at the emergency department bedside. However, telehealth services that connect PRCs with emergency department patients in real-time using secure communications technology are becoming more popular, and even less is known about the effectiveness of such programs as related to services and clinical outcomes. The current study sought to assess factors associated with successful post-discharge follow-up of patients with a history of opioid use who received PRC telehealth services while in the emergency department. **Methods:** Data come from records for 917 patients who engaged a telehealth PRC one or more times (1208 total engagements) at one of 13 emergency departments within the same large health system. A multilevel Poisson regression model was used to assess the degree to which variables predicted successful post-discharge follow-up by a PRC.

Results: Twenty-three percent of enrolled patients were successfully followed-up with at least once. Significant predictors of successful follow-up included patient employment at baseline (Incidence Rate Ratio [IRR]: 2.8, CI: 2.05-3.9), living in a rural area (IRR: 1.8, CI: 1.04-3.2), PRC provision of referrals (IRR: 1.7, CI: 1.2-2.2), number of emergency department presentations in previous 365 days (IRR: 0.99, CI: 0.98-0.99), and duration of the initial PRC telehealth interaction (IRR: 0.87, CI: 0.85-0.88). **Conclusions:** Understanding successful follow-up associated with telehealth engagement is of importance to the developing PRC profession, considering relationship development is one of their key functions. The results have potential utility for planning and implementing peer telehealth services in EDs and other locations, which is needed considering the expansion for peer telehealth services is likely to continue.

Pilot-testing the prototype of a smartphone application for smoking prevention and cessation among HIV care providers

Irene Tami-Maury¹, Samuel Tundealao², Jenna Guzman², Valeri Noe-Diaz³, Christine Markham², Karen Vigil²

¹University of Texas Health Science Center, Houston, United States,

²University of Texas Health Science Center Houston, United States,

³Universidad Intercontinental (UIC) in México City, Mexico

Background and Objectives: The diagnosis and continuous care of chronic conditions such as HIV present potential teachable moments for delivering smoking prevention and cessation interventions for patients. During our study, we designed and pre-tested a prototype of a smartphone application (app), Decision-T, specifically designed to assist physicians and non-physicians when providing personalized smoking prevention and cessation services to their patients.

Methods: We developed the Decision-T app based on the transtheoretical algorithm for smoking prevention and cessation following the 5 As model. Our study used a mixed-methods approach among 18 HIV care providers recruited from the Houston Metropolitan Area for pre-testing the app. Each participant took part in three mock sessions using the Decision-T app. The average time spent by the provider at each mock session was measured. We also measured accuracy by comparing the smoking prevention and cessation treatment offered by the HIV care provider using the app to the treatment approach chosen by a tobacco specialist who designed the case. The system usability scale (SUS) was used to assess usability quantitatively. Transcripts of individual interviews with study participants were analyzed to assess usability qualitatively. STATA 17/SE and NVivo Version 12 were used for quantitative and qualitative analysis, respectively. **Results:** The average time for completing each mock session was 5 minutes 17 seconds. The participants achieved an overall average accuracy of 88.89%. The average SUS score achieved was 87.5 (± 10.26). A total of five major themes (i.e., the apps contents are beneficial and straightforward, apps design is easy to understand, apps user experience is uncomplicated, apps tech is intuitive, app needs improvements) emerged after analyzing the qualitative interviews.

Conclusions: The Decision-T app has the potential to increase HIV care providers engagement in offering smoking prevention and cessation behavioral support and pharmacotherapy recommendations to their patients briefly and accurately.

DOI: 10.18332/popmed/164950

CORēHealth: operating center of telemedicine for chronic conditions and clinical networks

Giovanni Gorgoni¹, Pasquale Notarangelo², Vito Petrarolo³

¹Regional Agency for Health and Social Care of Apulia, Italy, ²AreSS Puglia,

Regional Agency for Health and Social Care of Apulia, Italy, ³Regional

Agency for Health and Social Care of Apulia (AreSS Puglia), Italy

Background and Objectives: The transformation of remote healthcare pathways (telemedicine) in Apulia starts a long time ago with the POR Puglia 2014-2020 projects: HLCM and TALIsMAN (winner of the Digital Innovation Award in Healthcare 2021) from which CORēHealth directly derives, set up at AreSS. **Methods:** CORēHealth offers: HL7-FHIR interoperable web-cloud platform; Televisit, teleconsultation, telemonitoring, telecooperation and teleconference; Device tracking system; patient synoptic; central alarms; Mobile App for Citizens (Android and iOS); Integration with the Regional Health Information System, the Electronic Health Record and others. **Results:** The APP promotes the patients involvement in the care process: keeping in touch with your specialist doctor and caregiver (video calls and chat); consult the agenda of the televised programs with your care team; view your care plan; enter the vital parameters that are communicated to the doctor in real time; manage their clinical diary and possibly share it with the care team; facilitate the measurement of compliance with the treatment path (drug intake, lifestyle). From January 2022 the transformation of the Apulian Oncological Network into a digital key was started and therefore the training of the operators of the Oncological Guidance Centers and the Breast Units and the enrollment of about 23,000 cancer patients. **Conclusions:** AreSS has launched a virtuous path of training, change management and digital literacy for all users of the system (medical and administrative teams) and for patients to promote continuous training and the consolidation of digital skills. CORēHealth overturns the traditional patient care pathways, bringing, for the first time, digital innovation directly into their hands (App Mobile) allowing them to have their own medical history, their treatment plan and to maintain a constant and regulated dialogue with your doctor, the medical team and the care giver, as well as being able to take the most suitable measurements for the management of your pathology.

Popul. Med. 2023;5(Supplement):A561
DOI: 10.18332/popmed/164989

Association between e-health literacy and vaccine hesitancy among non-health college students at King Faisal University

Abdullah Ramadan¹, Mohammed Abadi¹, Edric Estrella¹, Mohammed Habrity¹, Mujtaba Salman¹, Hussain Mokinah¹, Hashem Suwajj¹

¹King Faisal University, Saudi Arabia

Background and Objectives: Vaccine hesitancy has been rated among the top 10 global Public Health threats by the World Health Organization (WHO). Causes of vaccine hesitancy are heterogeneous and the media environment can negatively influence vaccination acceptance and contribute to vaccine hesitancy. The purpose of this study was to determine the association between eHealth literacy and vaccine hesitancy towards flu and HPV among non-health colleges students at King Faisal University.

Methods: This analytical cross-sectional study obtained data from 876 non-health undergraduates at King Faisal University selected through two-stage cluster sampling procedure. Two validated instruments, particularly, the eHealth Literacy Scale (eHEALS) and the Adult Vaccine hesitancy Scale were used. Statistical analysis was done using JASP. Logistic regression was performed to determine the association between the student's level of eHealth literacy and vaccine hesitancy towards flu and HPV.

Results: Half of the students had high eHealth literacy level. The estimated proportion of students who displayed hesitancy towards the HPV and flu vaccine was 52.85% (95%CI=49.49%-56.20%) with the statement "I am concerned about serious adverse effects of vaccines" (89% CI: 87.00%-91.00%) as the most prevalent reason for vaccine hesitancy. Students with high eHealth literacy were roughly three times more likely to be not vaccine hesitant ($p < .001$) compared to those with low eHealth literacy. **Conclusions:** The present data confirms that eHealth literacy was significantly associated with vaccine hesitancy which necessitates the university to take initiatives to further enhance the eHealth literacy levels of the non-health students by utilizing the electronic platforms to share credible health information. The Ministry of Health should also enhance their social media presence in order to spread reliable health information, specifically regrading vaccines and their safety.

AI governance in public health systems

Robyn Whittaker^{1,2}, Rosie Dobson³

¹Te Whatu Ora Waitemata, New Zealand, ²University of Auckland, Auckland, New Zealand, ³University of Auckland, New Zealand

Background: Artificial Intelligence (AI) tools are increasingly being introduced into practice within health systems globally. While great work has been done to develop and adapt ethical principles for AI in healthcare, there are few practical exemplars of implementing good governance of the Introduction of AI into practice. We will describe the AI Governance that has been put in place in Aotearoa New Zealand to guide the public health system on decisions and agreements around the development and use of AI tools.

Methods: Background research on existing international guidance (e.g. WHO 'Guidance on Ethics and Governance of AI for Health') and best practice (e.g. UK NHSX 'Artificial Intelligence: How to get it right.'), was conducted alongside technical AI advice. Surveys were conducted to determine patients' perspectives on the use of their health information for the development of AI. New Zealand specific requirements such as the National Ethical Standards, Algorithm Charter for Aotearoa NZ and the Māori Data Sovereignty charter and principles, were integrated. A Governance Group was established with diverse membership including consumers to develop a governance framework that considered all perspectives.

Results: A framework and checklist were developed that included nine areas for consideration: appropriateness of AI in this context, ethics, equity, technical, data, legal/contractual, and clinical, consumer and Māori perspectives. This checklist has been used to review proposals at all stages of the AI lifecycle for more than one year. It is now being used by a National Expert Advisory Group.

Conclusions: International guidance can provide the basis for local adaptation of principles that can be applied to the governance of the development and use of AI within national public health systems. The opportunity for AI is large but the potential to do harm is real, and therefore the implementation of AI tools in healthcare should be carefully considered.

The effect of WhatsApp group-based digital health interventions on increasing anemia knowledge in college female students

Andi Silwanah¹, Suriah Suriah¹, Nurhaedar Jafar¹, Intan Areni¹, Muh Zamaa², Nureli Nureli², Basri Basri², Rezky Yusuf³

¹Hasanuddin University Indonesia, Indonesia, ²Sekolah Tinggi Ilmu Kesehatan Makassar, Indonesia, ³Universitas Muslim Indonesia, Indonesia

Background: The prevalence of adolescent female anemia and reproductive age remains alarming. By 2025 globally, it is predicted that there will be an increase in prevalence by more than double by 31.2%. Data on the prevalence of Indonesian adolescents aged 15-24 years has increased, namely in 2013 by 18.4%, an increase of 26.8% in 2018, and this shows that Indonesia is a country with a worsening anemia rate that is difficult to reach the Global nutrition target (anemia) in 2025, namely 14.3%. This study Aims to determine the effect of group WhatsApp-based digital health interventions on improving anemia knowledge in female college students.

Methods: The type of research is pre-experimental, using a one-group pretest-posttest approach without a control group. The study sample was 36 female students, using the Purposive sampling technique.

Results: The study's results using the paired t-test showed an influence of group WhatsApp-based digital health interventions on the increase in anemia knowledge in female students p value = 0.012 < 0.05.

Conclusions: This study concludes that there is an influence of WhatsApp group-based digital intervention on increasing anemia knowledge among female college students, so this group WhatsApp-based digital health interventions method can be applied as one of the promotional efforts in the delivery of health education about anemia among women of productive age.

Keywords: anemia, digital intervention, WhatsApp, knowledge

Culturally safe eHealth: what is 'best practice' and who determines it?

Georgina Chelberg¹, Ray Mahoney¹, Charankarthi Musuwadi², Kaley Batten²

¹Commonwealth Scientific and Industrial Research Organisation, Australia,

²Commonwealth Scientific and Industrial Research Organisation, Herston, Australia

Background/Objective: Evidence for the relevance, effectiveness, and socio-cultural benefits of eHealth interventions with First Nations peoples is growing. In Australia, a research program is preparing a best practice framework (BPF) for eHealth with Aboriginal and Torres Strait Islander people [1]. The 7 phases aim to establish the themes and characteristics of culturally safe eHealth, as voiced by Aboriginal and Torres Strait Islander people.

Methods: A systematic literature review and scoping review were conducted (Phases 1 and (ii) what guidelines or best practice evidence should inform eHealth interventions with Aboriginal and Torres Strait Islander people. PROSPERO and Open Science Framework protocols were registered. Search strategies incorporated variations of 'eHealth'; 'Aboriginal and Torres Strait Islander health'; 'guidelines, ethics'. Database searches included Web of Science, Scopus, Cochrane, Embase, CINAHL, PubMed, PsycINFO, plus grey literature. Screening, data extraction and quality assessments were conducted by 3 authors, with narrative analysis to generate themes (Phase 3). Modified Delphi processes will confirm final themes and principles of the BPF (Phases 4-6). Delphi participants will include stakeholders of eHealth feasibility trials, subject matter experts, and community-controlled partners with expertise in Aboriginal and Torres Strait Islander health.

Results: The BPF scientific protocol was published in June 2022 [1]. Phases 1&2 commenced November 2022 with findings on-track for release in early 2023. In December 2022, qualitative data collection was completed for several eHealth feasibility trials with Aboriginal and Torres Strait Islander communities. Key findings from stakeholders will contribute to subsequent Delphi processes scheduled for May 2023. Dissemination of the foundational BPF is expected December 2023 (Phase 7). This presentation will highlight key findings from completed research phases.

Conclusions: A BPF will contribute to rigorous eHealth innovations that promote genuine co-design, ensure cultural safety and clinical effectiveness for Aboriginal and Torres Strait Islander people. [1]doi:10.2196/34904

A digital solution to support the Multidisciplinary Tumor Board activities: implementation process and impact analysis

Maria Specchia^{1,2}, Andrea Pilla², Maria Gambacorta^{1,2}, Alessandro Filippella²,

Flavia Beccia², Sara Farina², Elisa Meldolesi¹, Chiara Lanza¹, Rocco Bellantone^{1,2}, Vincenzo Valentini^{1,2}, Giampaolo Tortora^{1,2}

¹Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, ²Università Cattolica del Sacro Cuore, Rome, Italy

Background and Objective: Colorectal cancer (RC) is the third most common cancer, with an increasing incidence in recent years but also significant improvements in clinical outcomes. Modern treatment strategies are based on the close working of related disciplines within Multidisciplinary Tumour Boards (MTBs). This study has been aimed to implement a digital solution within the RC-MTB and analyse its impact in the context of the Fondazione Policlinico 'A. Gemelli' in Italy. **Methods:** A multidisciplinary working group was created for the platform customization according to the RC-MTB specific needs (definition of the data to be recorded and stored in the platform for each clinical case discussed) and its integration into the hospital IT system to allow the automatic import of patients' data. Subsequently, the platform was validated through a pilot test and operatively launched. The platform impact analysis was carried out through a pre-post comparison of the RC-MTB. Descriptive and inferential analyses were performed, with a p-value < 0.05 being considered statistically significant.

Results: The implementation of the platform allowed more healthcare professionals to attend meetings (p<0.001) and resulted in a decrease of patients sent to the RC-MTB for re-staging after radiotherapy-chemotherapy (RT-CT) (p=0.001) and an increase of patients sent to the RC-MTB for the definition of treatment strategies (p<0.001). The shared clinical decision "Needed further diagnostic investigation results" showed a significant reduction (p=0.023) and the "Referring patients for RT-CT" one a statistically significant increase (p<0.001). **Conclusions:** The study showed a positive impact of the platform for organizational and patient-related aspects. For future perspectives, a) the assessment of virtual MTBs impact could be expanded to other cancer diseases and analysed also in terms of processes (e.g. clinical paths timing/adherence to guidelines), and clinical outcomes (e.g. survival/quality of life); b) the IT platform could be used also for research and teaching activities.

How can we build public trust in personal data use in health systems? Evidence-based guidance

Felix Gille¹, Sarah Smith², Nicholas Mays³

¹University of Zurich, Switzerland, ²The London School of Hygiene & Tropical Medicine (LSHTM), United Kingdom, ³London School of Hygiene & Tropical Medicine (LSHTM), United Kingdom

Objective: Public trust in health systems is pivotal for their effective and efficient functioning. In particular, public trust is essential for personal data use, as demonstrated in debates in many countries, for example, about whether data from COVID-19 contact tracing apps should be pooled or remain on individuals' smartphones. Low levels of public trust pose a risk not only to health system legitimacy but can also harm population health. **Methods:** Synthesising our previous qualitative and theoretical research in the English National Health Service which enabled us to conceptualise the nature of public trust in health systems, we present guiding principles designed to rebuild public trust, if lost, and to maintain high levels of public trust in personal data use within the health system, if not.

Results: To build public trust, health system actors need to not rush trust building; engage with the public; keep the public safe; offer autonomy to the public; plan for diverse trust relationships; recognise that trust is shaped by both emotion and rational thought; represent the public interest; and work towards realising a net benefit for the health system and the public. **Conclusions:** Beyond policymakers and government officials, the guiding principles address a wide range of actors within health systems so that they can work collectively to build public trust. The guiding principles can be used to inform policymaking in health and health care and to analyse the performance of different governments to see if those governments that operate in greater conformity with the guiding principles perform better. This research is published in: Gille F, Smith S, Mays N. Evidence-based guiding principles to build public trust in personal data use in health systems. DIGITAL HEALTH. 2022;8. doi:10.1177/20552076221111947 [1] Links: ———[1] https://doi.org/10.1177/20552076221111947

Promoting physical activity among university students using social media or text messaging: a systematic review

Roberta Lo Bue¹, Alessandra Buja², Federico Mariotti³, Chiara Zampieri², Giovanni Leone², Stefano Tardivo⁴, Vincenzo Baldo²

¹Department of Cardiological, Thoracic and Vascular Sciences, and Public

Health, University of Padova, Italy, ²Department of Cardiological, Thoracic and Vascular Sciences, and Public Health, University of Padova, Italy, ³University of Padova, Italy, ⁴Department of Diagnostics and Public Health, Section of Hygiene, University of Verona, Italy

Background and Objective: Regular physical exercise lowers the risk of all-cause mortality and of various chronic diseases. Sedentary lifestyles are very common among college students. Individuals who do not engage in sufficient levels of physical activity at this age are at high risk of persisting in this behavior for the rest of their adult lives. New technologies, such as smartphones and social media, have been used successfully as health promotion tools in college populations. The purpose of this study was to conduct a systematic review of studies examining the effectiveness of interventions that used modern technologies to promote physical activity in college students, and to propose a protocol for such interventions based on the evidence emerging from the review. **Methods:** A systematic review was conducted on the PubMed and SCOPUS databases, considering studies published from 2012 to 2022 that aimed to assess the effectiveness of interventions to promote physical activities for college students using modern technologies. For a total of 19 articles selected, an evidence table was drawn up, and the quality of the studies was assessed using the PRISMA checklist.

Results: The interventions differed enormously in design, the strategies implemented and the types of outcome measure considered. Fifteen (79%) of the 19 studies reviewed demonstrated an improvement in participants' physical activity levels, while three studies (16%) found no such improvement, and a worsening of the baseline activity levels was reported in one study (5%). **Conclusions:** Interventions to improve college students' physical activity levels with the aid of modern technology tend to be effective. Many factors can influence the effectiveness of such interventions, however. For example, a gender-related difference emerged in students' participation in the studies reviewed, and the interventions proved more effective if they were accompanied by the creation of social groups.

How to measure digital public health system maturity on a national level: an international interdisciplinary Delphi study

Laura Maaß^{1,2}

¹Research Center on Inequality and Social Policy (Socium), University of Bremen, Bremen, Germany, ²Leibniz ScienceCampus Digital Public Health Bremen, Bremen, Germany

Background and Objective: The COVID-19 pandemic showed how crucial digital public health (DiPH) interventions are for continuous treatment and system sustainability. Several studies highlighted how the digital system transformation might improve access to and quality of healthcare services. However, there is no consensus on how to best assess the national readiness for the digitalization of such systems. Therefore, this Delphi study aimed to collect indicators to measure the maturity of DiPH systems nationally.

Methods: The three-stage international and interdisciplinary Delphi study included 82 participants. During the first round, participants were invited to propose indicators to measure maturity among the technological and legal requirements of DiPH tools, the willingness of the general public to use them, and the degree of application of DiPH tools to the national healthcare system. The suggestions were qualitatively assessed and presented for ranking on a 4-point Likert scale during the second round. Experts were also able to rephrase or add indicators. In the third round, experts could only rank indicators.

Results: 106 indicators to measure the maturity of DiPH systems were included. Of these, 33 fall under the legal and 30 under the technological requirements. 27 assess the social level and 16 the degree of application. All dimensions can be clustered further into 3-4 sub-groups each. The qualitative analysis pointed to the importance of data protection regulations, affordable access to smartphones and the internet, interoperability between interventions, financial incentives, user motivation and literacy, and whether interventions were implemented as local pilots or national system services.

Conclusions: The study identified indicators for interdisciplinary assessing DiPH system maturity. While this Delphi can't answer how best to integrate these indicators into national health system evaluation procedures, this approach is an essential first step towards an index to measure the maturity of DiPH systems.

Adjusting to digital change: learnings from five hospitals using mHealth for gestational diabetes management

Kaley Butten¹, Marlien Varnfield¹

¹Australian eHealth Research Centre, CSIRO, Australia

Background and Objective: Mobile health (mHealth) platforms are becoming increasingly common as health services try to meet the growing demand for quality care in managing chronic health conditions. Conditions such as gestational diabetes which require consistent record-keeping and monitoring lend themselves to digital solutions, yet the implementation of these technologies remains challenged. The Objective of this study was to examine the change management experiences of stakeholders utilising the MoTher platform which consists of a patient facing App and a web-based clinician dashboard, to support the management of gestational diabetes across five Australian hospitals.

Methods: A mixed-methods approach has been used to understand stakeholder experiences implementing MoTher. Clinicians, project staff including engineers across five Australian hospitals where the platform has been used with 5000+ patients since June 2020 are sharing their views in interviews and contributing via a survey based on the Unified Theory of Acceptance and Use of Technology (UTAUT). Additionally, communications and pain points raised with project staff across study sites are being thematically analysed to understand common and potentially overlooked implementation challenges.

Results: Preliminary findings (final results expected by conference date) suggest that the Introduction of mHealth has had multi-level implications, particularly in the health service eco-system, affecting care-coordination, staffing, allocation of resources, billing, and potentially other service models (with clinical outcomes reported to be affected).

Conclusions: Although the COVID-19 pandemic has given innovation a nudge, mHealth is not a brand-new option for health service support. Research suggests there has been a lack of appropriate change management principles within health systems which has delayed adoption. Initial takeaways from this study suggest there is room for more structured frameworks to support technology transitions, particularly for clinicians and services. This study will provide important learnings which can inform future digital health integration, supporting the change management process and long-term sustainability.

DOI: 10.18332/popmed/165239

Exploiting digital social diffusion: problematic dissemination of prescription drug news in Latin America

Matthew Flynn¹, Andres Lombana-Bermudez²

¹Georgia Southern University, United States, ²Pontificia Universidad Javeriana, Colombia

Background and Objective: Due to public health concerns, most countries of the world ban companies from directly advertising medicines to the public. However, the rise of new digital media allows for the dissemination of information that does not promote the rational use of prescription drugs. The objective of this study is to evaluate reports on medicines and analyze their diffusion on social media platforms.

Methods: This study searched for the top 19 drugs sold in 2018 using Media Cloud, an engine that organizes digital media on the Internet and places them in a database, published in Brazil, Argentina, Mexico, Chile, Peru, and Colombia. Three coders decided on the following criteria: Source of information (news media, op-ed, university, company, government, NGO); Propaganda (Yes/No/Maybe); Content (new treatment, abuse, regulation, price, industry, other); Tone (neutral, laudatory, critical); and Adverse Reactions (ADRs) mentioned (Yes/No).

Results: A total of 424 stories mentioning the top brands (329 in Spanish, 95 in Portuguese) were collected. A subgroup of 213 stories was shared on Facebook (FB) (141 in SP, 72 in PT), of which 35 stories had more than 100 FB shares. The count of articles coded as laudatory, critical, and neutral are 75, 91, and 47, respectively, and a majority (N=155) not mentioning ADRs. For stories shared more than 100 times on FB, 19 were coded as laudatory compared to critical (N=10) or neutral (N=6), and stories not mentioning ADRs (N=25) totaled more than those that did not (N=10).

Conclusions: Prescription drug news with laudatory frames as well as content that fails to mention potential side effects appears to disseminate more on social media.

Association of waiting time and satisfaction level of patients with online registration system in a tertiary level medical institute Outpatient Department (OPD)- a case control study

Arun Aggarwal¹, Nitika Sharma², Pankaj Arora³, Pankaj Bahuguna¹

¹Department of Community Medicine, School of Public Health, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India,

²Postgraduate Institute of Medical Education and Research, Department of Community Medicine and School of Public Health, Chandigarh, India,

³Department of Hospital Administration, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India

Background and Objectives: In 2015 the Government of India started a Computerized Online Registration System (CORS) for scheduling online appointments. This study was conducted to assess whether the Introduction of CORS had any impact on patient satisfaction and patient waiting time for outpatient registration.

Methods: A study comprising 50 online registered patients and 70 walk-in registered patients was conducted at the adult outpatient departments registration windows (Internal Medicine and General Surgery) of a tertiary level hospital. A pre-tested interview schedule was used to capture the satisfaction levels (%), waiting time (in minutes) and their associated factors in both group of patients.

Results: The Median waiting time for walk-in registered patients was approximately four times (60 minutes, IQR (30-90)) as compared to the online registered patients (15 minutes, IQR (10-30)) (p=0.000). The satisfaction level among the online registered patients (90%, 95% CI (83-97)) was three times higher than the walk-in registered patients (29%, 95% CI (18-40)). The online registered patients were ten times more likely to be satisfied as compared to the walk-in registered patients (Adjusted Odds Ratio 9.8, 95% CI (2.2-43.5)). Additionally, for every 1% increase in the waiting time at the online registration window (>30 minutes) the satisfaction decreased by 3% (-3.2%).

Conclusions: The study showed that the CORS improved the user experience by reducing the waiting time and increasing the satisfaction levels at the registration window.

Data sharing barriers and enablers for healthcare Artificial Intelligence (AI) in Low- and Middle-income countries

Capucine Barcellona¹, Aprajita Kaushik¹, Nikita Mandyam², Si Tan², Jasper Tromp²

¹Saw Swee Hock School of Public Health, National University of Singapore, Singapore, ²National University of Singapore

Background: Health systems in low- and middle-income countries (LMICs) can greatly benefit from AI interventions, including electronic decision support tools and predictive analytics. Unfortunately, challenges to data sharing pose a significant obstacle to the development and use of AI in healthcare.

Objective: This systematic review identified barriers to and enablers for data sharing related to AI in healthcare in LMICs.

Methods: A systematic literature search was performed using PubMed, SCOPUS, Embase, Web of Science and ACM (Association for Computing Machinery) for articles describing barriers to and enablers for data sharing for AI in healthcare in LMICs. Qualitative data extraction and thematic analysis was conducted on selected studies. Barriers and enablers were classified according to a framework formulated by merging two existing framework (Panhuis 2014 and Sun and Medaglia 2019), comprising eight categories: 1) Technical, 2) Motivational, 3) Economic, 4) Political, Legal and Policy, 5) Ethical, 6) Social, 7) Organisational and Managerial and 8) Data-related.

Results: The systematic search identified 2471 records, of which 22 met the eligibility criteria. The studies were from 13 countries, with the majority from Africa (12 studies, 55%) and Asia (6 studies, 27%). The most important barriers were technical (e.g. lack of hospital infrastructure) and data-related (e.g. lack of interoperability standards). Significant enablers for data sharing included political and regulatory enablers (e.g. government support, clear policies and guidelines on data sharing) and technical enablers (e.g. shifting from paper-based to electronic data collection).

Conclusions: This systematic review identified various barriers and enablers relevant to LMICs. These results can inform context-specific recommendations to promote local AI development in resource-limited settings. Recommendations and best practices arising from this review can also indicate ways to mitigate common data sharing barriers for transitioning economies and health systems.

Machine learning prediction of suicidal ideation among college students during the COVID-19 pandemic

Mélissa Macalli¹, Marie Navarro¹, Océane Pic¹, Nathalie Texier², Stéphane Schück², Christophe Tzourio¹

¹University of Bordeaux, France, ²Kappa Santé, France

Background and Objective: College students are particularly vulnerable to mental health problems, including suicidal ideation. The COVID-19 pandemic, and the

restrictive measures imposed to limit the spread of the virus, such as lockdown or university closures, have increased the vulnerability of college students to mental health problems. In this particular epidemic context, our objectives were to (1) develop a predictive model of suicidal ideation among college students with a machine learning model; and (2) identify the most predictive factors.

Methods: We used random forest models to predict suicidal ideation among 346 French college students involved in the French CONFINS longitudinal cohort. We created models for predicting suicidal ideation at follow-up, based on 128 potential predictors reported at baseline that reflected socio-demographics, health, lifestyle habits, familial characteristics, and COVID-19-related characteristics.

Results: The most important predictors identified were depressive symptoms, self-reported mood, and anxiety symptoms. The predictive models showed moderately good mean values for the area under the receiver operating characteristic curve (0.74), sensitivity (0.69), specificity (0.74), and negative predictive value (0.89). To a lesser degree, the level of stress before the COVID-19 pandemic, optimism about the quality of life after lockdown, and health literacy contributed to the suicidal ideation prediction. In a subsample of students that did not report suicidal ideation at baseline, the main predictors were quite similar.

Conclusions: Few factors were required for predicting the SI. The strongest predictors were related to the college student's mental health, and they were not specific to the pandemic. These findings may facilitate the development of a routine screening tool for the early identification of students at risk.

Exploring maternal mortality in Southern Ethiopia: a qualitative study

Niguse Kara¹, Mary Codd², Takele Tadesse³, Abenet Desalegn⁴

¹School of Public health, Wolaita Sodo University, Wolaita Sodo, Ethiopia,

²School of Public Health, Physiotherapy and Sport Science, University College Dublin, Ireland, ³School of Public health, Wolaita Sodo University, Sodo, Ethiopia, ⁴School of Medicine, Wolaita Sodo University, Wolaita Sodo, Ethiopia

Background: Maternal mortality in Ethiopia is the fifth highest in the world, estimated to be 401/100000 population. Even though Ethiopia has been applying strategies to reduce maternal mortality such as Basic (BEmOC) and Comprehensive Emergency Obstetric Care (CEmOC), upgrading health facilities, training health officers and midwives, providing institutions with essential equipment, and regular monitoring and supervision, maternal mortality is still unacceptably high. The objective of this study is to explore factors associated with maternal deaths in the Wolaita Zone, Southern Ethiopia.

Methods: The study used a grounded theory method with theoretical sampling. Four focus group Discussions (FGD) with 24 health care providers at four hospitals, and in-depth interviews with 10 family members of deceased mothers in Wolaita Zone who were identified from hospital records and from maternal death response officers and health extension workers in the district were carried out. All interviews and focused Group Discussion (FGD) were recorded, transcribed, and analysed using NVivo software with constant comparison analysis.

Results: Grounded data from FGD and in-depth interviews revealed factors very likely associated with and contributing to the high maternal death from health care providers and deceased family perspectives. The findings evolved as important were heavy bleeding, uterine rupture, delay in decisions to seek care, delay in getting to hospitals, and delay in receiving adequate health care.

Conclusions: To reduce maternal mortality to Sustainable Development Goal (SDG) 2030 level, maternal complications found in this study along with others should be given critical emphasis from service users, health care providers and government.

Data quality assessment of mHealth systems: strengths, potential limitations and opportunities for improvement; Case of Yendanafe system in Neno District, Malawi

Othniel Nimbabazi¹, Macdonald Kudambo², Fabien Munyaneza³, Rex Wong⁴, Chiyembekezo Kachimanga⁵, Karim Benali⁶

¹University of Global Health Equity, Rwanda, ²University of Global Health Equity, Malawi, ³Partners in Health Malawi, Rwanda, ⁴University of Global Health Equity, United States, ⁵Partners in Health Malawi, Malawi, ⁶Havard University, Algeria

Background: Good quality data enables proper decision making in healthcare settings leading to better planning, higher management efficiency and improved patient outcomes. The Yendanafe data system in Malawi was designed to

promote comprehensive patient care and improve public health services through an evidence-based approach. This study assessed the quality of the Yendanafe data system.

Methods: All available data in the Yendanafe data system for the year 2021 were analyzed in their data completeness, timeliness, accuracy, and consistency by measuring against the who recommended standards. A quantitative survey was conducted on a random sample of community health workers at six participating sites to identify end-user perspectives on the system and potential sources of variability.

Results: The median completion rate was 100%, significantly higher than the who recommended standard of 90% ($p=0.043$). The overall timeliness of the Yendanafe system was 87.4%, significantly higher than the who recommended score of 80% ($p>0.001$). The overall average accuracy rate was 48.8%, significantly below the who recommended accuracy rate of 95% ($p>0.001$). The overall consistency was 98.77%. The strength of the system included having a language that is easy to understand (86%), having enough time to synchronize data into database (89%) and the ability to make edits in case information is wrongly filled (88%). However, some respondents found the phone were not user-friendly (86%), the system operated slowly (75%) and limited previous experience in collecting data via phone (85%).

Conclusions: The Yendanafe system is an innovative and powerful tool that has the potential to revolutionize data collection and use to contribute positively to the improvement of the healthcare system in Malawi. Future studies to validate the accuracy of the Yendanafe system and to assess the accuracy of EMR data systems are needed. More technical support was needed and the design of the system could be improved.

DOI: 10.18332/popmed/165432

Medical artificial intelligence readiness of medical students in Türkiye

Sevda Sungur¹, Didem Oktar¹, Selma Metintas¹, Muhammed Onsuz¹, Mediha Bal¹

¹Department of Public Health, Faculty of Medicine, Eskisehir Osmangazi University, Eskisehir, Türkiye

Background and Objectives: Medical artificial intelligence readiness (MAIR) is the state of readiness of the health care provider in the knowledge, skills and attitude to use health care-Artificial intelligence (AI) applications in its mix with their own professional knowledge. The study aimed to measure the MAIR level of medical students and related variables amalgam with own professional knowledge and related variables. **Methods:** This cross-sectional study was conducted on 108,876 medical students in Türkiye in the 2022 spring semester. In the questionnaire, sociodemographic characteristics, participants thoughts on AI and AI usage areas were questioned. MAIR was measured with the MAIR Scale for medical students (MAIRS-MS). MAIRS-MS was found to be a valid and reliable (Cronbach's alpha 0.87) for evaluating and monitoring medical students' on AI technologies and applications. The questionnaire was administered on digital platforms with online Google forms.

Results: The study group consisted of 2407 students, 55.6% of whom were female. The scores obtained from the scale ranged 22-110, with a median of 67. Of 60.4% students scored above the average. Among the areas where AI is used in health services, the most known was medical imaging with 59.3%, and the least known was early response planning and needs analysis for disasters with 17.9%. MAIR level was higher in those who had heard of AI before, studied AI, knew the use of AI in medicine, reported more than three areas of AI in medicine ($p<0.001$). Of 70.0% students thought that AI should be included in their curriculum. The students stated that AI is safe in medicine (47.8%), can be used in their professional business work (44.3%), but it might be abused (43.4%). **Conclusions:** The AI readiness level of future physicians is moderate. More educational programs for the applications of AI in medicine are recommended for medical students.

Patient satisfaction on the utilization of Video Observed Therapy (VOT) at the Vicente Sotto Memorial Medical Center (VSMMC), Cebu City, Programmatic Management of Drug Resistant Tuberculosis Satellite Treatment Center (PMDT STC) during the COVID-19 pandemic

Anro Begontes¹, Grace Melchor¹, Alfredo Lim¹, Vince Araneta¹

¹Vicente Sotto Memorial Medical Center, Cebu City, Philippines

Introduction: The face-to-face directly observed treatment (DOT) of multi drug resistant tuberculosis (MDRTB) was constrained by the implementation

of community lockdowns and travel restrictions to contain the Severe Acute Respiratory Syndrome Corona Virus-2 (SARS CoV-2). The pandemic resulted in disruptions of the usual operations in almost all sectors of the Philippines. The development of a new strategy like video telephony technology in healthcare have raised the remote video-observed treatment (VOT) as an alternative approach to DOT for monitoring. The utilization of this new strategy in our present setting in Cebu City, Philippines has to be explored yet.

Objective: To assess and determine the patient's satisfaction on the utilization of VOT among MDR Tuberculosis patients in the time of COVID 19 pandemic at the PMDT – VSMC from May 2022-July 2022.

Methods: A purposive sampling method was utilized involving the enrolled patients at PMDT STC. The patient satisfaction with VOT was measured using survey questionnaires from the study of Sekandi et al., (2020).

Design: The study design used in this research were both descriptive and analytical cross-sectional study during the COVID-19 pandemic within the time period of May 2022 to July 2022).

Results: Among the 45 respondents, 95.6 % were satisfied with the mode of therapy and 4.4 % were not. Most of the patients, 55.6%, recommend the VOT in the management of MDR TB. The Fisher's Exact Test showed that there were no significant associations existing among the different demographic parameters.

Conclusions: Video Observed therapy is an acceptable method of monitoring among patients receiving MDR TB treatment in VSMC, wherein the respondents of the study were satisfied with this mode of therapy and recommends its use. This innovative mode of treatment can be used in a pandemic period wherein lockdowns or travel restrictions interfere with DOT.

DOI: 10.18332/popmed/165465

Italy's journey throughout the pandemic: sentiments and attitudes in 2 million tweets

Andriy Melnyk¹, Andrea Agostini², Mario Nurchis³, Gerardo Altamura¹, Chiara Cadeddu¹, Fidelia Cascini⁴, Walter Ricciardi⁴

¹Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Roma, Italy, ²ETH Zurich, Switzerland, ³Department of Woman and Child Health and Public Health, Fondazione Policlinico Universitario A. Gemelli IRCCS, Italy, ⁴Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy

Background and Objective: Artificial Intelligence (AI) and Machine Learning (ML) techniques offer an opportunity for profound analysis of public attitudes, sentiments, and key discussion topics from a diverse range of sources, including social media data. Among social media platforms, Twitter offers a unique and potentially powerful data source due to its ease of access, real-time nature and support for academic endeavors. The analysis of tweets allows identification of dominant themes, topics, and changing trends pertaining to the pandemic, lockdowns and vaccinations. This might fundamentally improve public health programs, policies and vaccine rollout strategies both locally and nationally.

Methods: Twitter API v2 for academic purposes was used to extract Italian language tweets using a keyword set. Daily twitter volume and 2000 sample tweets per day were obtained from February 21st, 2020, to December 1st, 2022. A hybrid algorithm combining a rules-based approach and machine learning, specifically tuned for Italian, classified tweets according to sentiment (positive or negative) and topics (topic modelling). Weighing daily twitter volume, a Regression Discontinuity Design was used to identify changes in attitudes around a spectrum of relevant national events (e.g., pandemic, policies, COVID Certificate).

Results: More than 2,000,000 tweets were analyzed. Topics of discussion identified ranged from restrictive measures to economic stability. The model identified a change in positive attitudes and daily twitter volume around specific events, such as the first COVID-19 cases, the implementation of COVID-19 zones, vaccine related news and the implementation of the Green Pass.

Conclusions: Pandemic response strategies necessitate a deep understanding of the relationship between public health policies and population attitudes towards restrictive measures, vaccinations and their effect on people's lives. Applying AI and ML techniques on social media allows policy makers to improve their decision making for the current pandemic and future ones.

Prediction models for intrauterine growth restriction using artificial intelligence and machine learning: a systematic review and meta-analysis

Riccardo Rescinito¹, Matteo Ratti¹, Massimiliano Panella²

¹Department of Translational Medicine (DiMeT), Università del Piemonte

Oriente, Novara, Italy, ²Department of Translational Medicine (DiMeT), Università del Piemonte orientale, Novara, Italy

Intrauterine growth restriction (IUGR) is a fetal restriction associated with an abnormal fetal growth rate and has major implications for neonatal health. Artificial intelligence (AI) and machine learning (ML) models are increasingly being used to identify risk factors and provide early prediction of IUGR. We performed a systematic review (SR) and meta-analysis (MA) aimed to evaluate the use of AI/ML models in detecting fetuses at risk of IUGR. This SR was conducted according to the PRISMA checklist. SR included 14 studies reporting the performances of AI/ML models for the prediction of IUGR, of which 10 studies were used for meta-analysis. In the SR, the variables or data analyzed in the studies to predict IUGR were the fetal heart rate (n=7, 50%), biochemical or biological markers (n=4, 29%), DNA profiling data (n=2, 14%), and MRI data (n=1, 7%). Overall, we found that AI/ML techniques could be effective in predicting and identifying fetuses at risk for IUGR during pregnancy with the following pooled overall diagnostic performance: sensitivity = 0.84 (0.80 - 0.88), specificity = 0.87 (95% CI 0.83 - 0.90), positive predictive value = 0.78 (0.68 - 0.86), negative predictive value = 0.91 (0.86 - 0.94) and diagnostic odds ratio = 30.97 (19.34 - 49.59). In detail, the RBF-SVM (Radial Basis Function - Support Vector Machine) model (with 93% accuracy) showed the best Results in predicting IUGR from FHR parameters derived from CTG. In Conclusions: Our findings showed that AI/ML could be part of a more accurate and cost-effective screening method for IUGR and be of help in optimizing pregnancy outcomes. However, before the introduction into clinical daily practice, an appropriate algorithmic improvement and refinement is needed, and the importance of quality assessment and uniform diagnostic criteria should be further emphasized.

DOI: 10.18332/popmed/165587

Analysis of the specialist outpatient visits potentially deliverable via telehealth: a cross-sectional study

Toni Cappelletti¹, Giacomo Scaioi¹, Veronique Sotong², Aldo Angelis¹, Giuseppina Moro¹, Fabrizio Bert¹, Roberta Siliquini¹

¹Department of Public Health Sciences, University of Turin, Italy, ²University of Turin, Italy

Background and Objective: Telemedicine is a useful tool to deliver care to patients who have difficulties to reach healthcare facilities. During the recent COVID-19 pandemic period, the use of telemedicine increased exponentially. However, the use of this tool could be further incremented. The aim of this study was to analyze the prevalence of specialist outpatient visits currently delivered in presence that can be delivered via telemedicine, and the potential predictors of the willingness of the patients to use this tool.

Methods: A cross-sectional study was conducted in outpatient facilities located in Piedmont, Italy. Patients referred to Neurology, Diabetology/Endocrinology, and Pediatrics were included in the study. A 40-items survey was administered by trained researchers to the patients who were waiting for the visits. Characteristics of the visits ("first visit" or "follow-up visit", use of medical devices) were also retrieved. Specific criteria were defined to select the visits that could be potentially delivered in telemedicine.

Results: A total of 287 patients were included (115 pediatrics, 124 diabetology/endocrinology, 48 neurology). The percentage of specialist outpatient visits that could be provided via telemedicine was 2.6% for pediatric visits and 5.2% for other specialties. When considering deliverable in telemedicine also the visits in which medical devices were used, the percentages reached 38.7% overall. In 51.9% of cases, the assisted person declared the willingness to do the visit via telemedicine. Potential predictors of this willingness were the educational level and the age of the person.

Conclusions: Patients demonstrated the willingness to use telemedicine for specialist outpatient visits. However, to date it is difficult to increase the number of visits that can be provided remotely. There is the need of investments in new technologies, and to raise awareness among the most hesitant categories of persons about the use of this service.

A novel geographic ecological momentary assessment tool used to measure wellbeing and sleep quality based on exposure to parks

Alexander Wray¹, Sean Doherty², Jed Long¹, Jinyung Lee¹, Dan Rainham³, Jason Gilliland^{4,5,6,7}

¹Department of Geography and Environment, The University of Western Ontario, Canada, ²Department of Geography and Environmental Studies, Wilfrid Laurier University, Canada, ³School of Health and Human

Performance, Dalhousie University, Canada, ⁴Department of Geography & Environment, The University of Western Ontario, Canada, ⁵Department of Epidemiology & Biostatistics, The University of Western Ontario, Canada, ⁶Department of Pediatrics, The University of Western Ontario, Canada, ⁷School of Health Studies, The University of Western Ontario, Canada

Background: Parks and recreational facilities in the Canadian context are critically important to overall wellbeing as they provide opportunities to connect with nature, mitigate climate change, and facilitate social connections for the entire population. The ParkSeek project is a national research initiative funded by the Public Health Agency of Canada to establish a self-sustaining suite of tools to support the surveillance of parks and recreational facilities as health promoting resources. **Methods:** A geographic ecological momentary assessment tool (GEMA) was developed to survey participants via their smartphone device in real-time about their experiences in parks, relating it to their WHO-5 wellbeing score, and sleep quality score. Participants complete these surveys twice per day, and whenever entering or exiting a park. Participants were recruited from the mid-sized Canadian cities of London, Ontario and Waterloo, Ontario. In addition, the research team evaluated the physical features of parks visited by participants using a standardized audit tool and incorporated these features into analyses of park experiences and wellbeing outcomes.

Results: Pilot results demonstrate participants engage with parks based on their perceived features rather than objective features as measured by the research team, with moderate changes to their self-reported wellbeing and sleep quality scores. The time spent in parks, and daily exposure to greenness outside of parks may mediate these relationships. **Conclusions:** The advent of "park prescriptions" in Canadian primary care and public health practice requires further monitoring and evaluation. The ParkSeek GEMA could be used to monitor the effectiveness of these prescriptions in responding to mental wellbeing and physical health conditions.

Territorial health digitalization in a Local Health Authority of central Italy

Michele Totaro¹, Mauro Pitorri¹, Antonio Boncompagni¹, Francesca Fornara¹, Ottavio Fasciolo¹, Marinella D'Innocenzo¹, Anna Petti¹, Assunta Luca¹

¹ASL Rieti, Italy

Background and Objective: COVID-19 forced health systems to embrace newer methods of health data sharing, in order to reduce patients' transfers, thus decreasing the risk of communicable diseases. The so-called "once only" strategy allows to centrally collect health data in an electronic health record (EHR), and avoid incomplete data from non-digital records such as papers or anamneses. Health digitalization is one of the main goals of Italian National Recovery and Resilience Plan.

Methods: We analyzed previous non-digital processes and defined possible interventions in the Local Health Authority (LHA) of Rieti, in central Italy. Medical prescriptions of general practitioners (GPs) are the starting point of every non-urgent territorial health process. Prescriptions were mostly sent in paper. Paper prescriptions were collected, associated to a paper patient dossier, and then physically sent to clinical providers (nurses, specialists, physiotherapists), in order to schedule and then execute the prescribed services. After performing the service, a copy of the report was then returned on paper in order to be filed and stored.

Results: In the actual process, digital prescriptions are directly acquired from GPs or scanned at arrival. Prescriptions are then uploaded in the local EHR, associated to patient file. Digital prescriptions are then assigned to the appropriate clinical provider, who can directly schedule the service in the EHR itself. The execution of the service is then signaled, with the possibility to write the report directly on the EHR, or attach a scanned copy. The system lets also fine monitoring of timing from prescription to schedule and execution, thus allowing detailed quality management.

Conclusions: The adoption of an EHR in Rieti LHA, after COVID-19 outbreak, lent to an improvement in the quality of care. EHR reduced the risk of errors and improved humanization of care.

The "PAITA" study: a multicentric cross-sectional study on physicians' attitude and trust towards Artificial Intelligence applications in healthcare

Valentina Nicolò¹, Corrado Vito², Paolo Villari²

¹Sapienza Università di Roma, Rome, Italy, ²La Sapienza, Italy

Background and Aim: In this study we intend to build a model to evaluate the attitude of Italian doctors towards AI applications in medicine and evaluate the factors that predispose them to be more favourable to its use. **Methods:** A 27-item questionnaire was distributed from September 1 and October 15 2022 to physicians from different healthcare facilities and with different background, using snowball technique. **Statistical analysis:** First, the descriptive statistics were made. A confirmatory factor analysis was performed to reduce the items on the Aptitude for AI scale and the reliability was evaluated through the Cronbach's alpha index. To predict the new variable, a multiple linear regression was performed. Finally, to classify the units into groups, a hierarchical and then, a non-hierarchical cluster were performed. For all tests the significance level considered was $p < 0.05$. Analyses were conducted with Stata v16 software.

Results: Globally 500 physicians fully responded; 54% men, mean age 50.53 years (SD +/-15.54), 38% of whom with more than 30 years of professional experience. The factor of AI explained 83% of the original variability and Cronbach's alpha was 0.81. The variables statistically significant in the regression model were Telemedicine, Clinical decision support system, Training and education of physician, Multi professional teams, Partnership, AI systems final supervision and Equity, with $R^2 = 0.6761$. The subdivision in clusters was associated only with the type of use ($X^2 = 41.9499$; $p < 0.001$) and not with gender ($X^2 = 1.1471$; $pV = 0.284$); area of competence ($X^2 = 7.0801$; $pV = 0.528$) and professional experience ($X^2 = 5.7251$; $pV = 0.221$). **Conclusions:** PAITA is the first study with the aim of assessing Italian doctors' attitudes toward AI and its results might represent a starting point for monitoring doctors' trust and issues regarding AI in the medical field in order to entail several future interventions.

Mobile-assisted medication adherence support intervention among tuberculosis patients: a parallel group randomized control trial

Zekariyas Sahile¹, Anthony Maeder², Lua Perimal-Lewis², Paul Arbon²

¹Flinders University Ambo University, Department of Public Health Ethiopia,

²Flinders University Australia

Background: There is conflicting evidence regarding the efficacy of SMS texts to promote TB medication adherence. Thus, we developed a mobile-assisted medication adherence support (Ma-MAS) intervention using the medical research council (MRC) framework based in a local context targeting audience needs and the effectiveness of this intervention evaluated in a sample of TB patients in Addis Ababa, Ethiopia.

Methods: A parallel group randomized control trial design was used to evaluate the effectiveness of Ma-MAS intervention. In total, 186 adult TB patients (93 per group) were randomly assigned 1:1 to one of the two groups. Participants in the Ma-MAS group received daily SMS texts and weekly phone calls regarding their daily medication intake and reminders to attend clinic visits for 8 weeks. Participants in the control group did not receive SMS texts or phone calls but received the same routine standard care as the Ma-MAS group. The primary outcome was the proportion of adherence measured by urine tests for isoniazid (INH) metabolites at the end of the 4th and 8th week of follow-up period. Analysis of a multivariable binomial generalized linear model was employed to evaluate the effect of Ma-MAS at P value < 0.05 .

Results: Ma-MAS significantly improved adherence to TB medications by 15.25% (95%CI: 5.38, 25.12; P -value=0.0065) after 8 weeks of intervention compared to the standard care alone in the control group. At the end of the 8 weeks follow-up period, the predicted probability of adherence to TB medication in the Ma-MAS group was 86% (95%CI: 81, 93), and in the control group was 70% (95%CI: 61, 79). Ma-MAS also improved adherence to TB medication by 15.30% (95%CI: 6.68, 23.90; P -value=0.0022) after 4 weeks of intervention compared with the control group.

Conclusion: Ma-MAS intervention based on information-motivation-behavioural skills model and behavioural change techniques is useful to improve adherence to TB medication.

The Italian national artificial intelligence platform to enhance health experience and outcomes

Domenico Mantoan¹, Elettra Carini¹, Alice Borghini¹, Simone Furfaro¹, Roberta Cusi¹, Domenico Mantoan¹

¹National Agency for Regional Health Services (AGENAS), Via Piemonte 60, 00187 Rome, Italy

Background and Objective: Even though the potential of Artificial Intelligence (AI)

in health is undeniable, still there are many issues that concern the users such as privacy, the complex and opaque relationships between analysis performed by AI and clinical output, efficacy and effectiveness of AI tools. The aim of this study is to analyse the impact of the introduction of a national AI platform for primary care. Methods: A before-and-after study will be performed by AGENAS to analyse the efficiency and effectiveness of the AI platform over a time span of 12 months of implementation. A sample of General Practitioners (GPs) working in the community health houses using the AI platform will be selected and indicators will be analysed at baseline, 6 and 12 months. A survey to analyse satisfaction of patients and GPs will be carried out.

Results: The national AI platform is funded with 40 million euros by NextGenerationEU plan and a call is ongoing to commit its realization. The first release of the AI platform will be implemented by 2024. The overall number of GPs in Italy is 39.270, the sample will involve a significant number of them, at least 1 doctor per urban zone (as defined by Istat) per region. The indicators measured will be about the utilization of the platform, changes in diagnosis and therapy. The questionnaire will survey the satisfaction of both patients and GPs using the platform.

Conclusion: The implementation of the AI platform is expected to enhance access to health services for patients, and accuracy and timeliness of diagnosis and therapy for professionals as well as enhance the experience of care and reduce the administrative burden on professionals. Digitalisation and AI can produce massive changes in health and can lead to a new era in health delivery.

DOI: 10.18332/popmed/163710

Moral health resources assessment using Mobile Application Rating Scale (MARS)

Hyewon Lee¹, Hyewon Lee¹, Oral Health Workgroup, WPHFA²

¹World Federation of Public Health, Seoul National University School of Dentistry and Dental Research Institute, Korea, Republic Of, ²World Federation of Public Health, Switzerland

This presentation aims to showcase how the World Federation of Public Health Association's (WPHFA) oral health workgroup identified assessment tools and a set of questionnaires to evaluate moral health and web-based resources that promote oral health literacy and training in oral health.

The presentation will showcase how the oral health workgroup from 13 different countries identified moral health and web-based resources and evaluated them using mars and other questions. The presentation will also discuss the dissemination of such resources, which align with the first two priority goals of the WHO's implementation guide on mobile technologies for oral health.

In 2021, the WHO published a guideline on moral health focused on promoting oral health, training health workers, detecting oral health conditions, collecting epidemiological data, and monitoring the quality of patient care. The WPHFA oral health workgroup consists of 24 public health dental leaders from 13 different countries. The group discussed the quality assessment of such moral health or other online sources and selected the mars scale and other customized questionnaires to perform expert panel evaluation for mobile or online oral health resources. The mars is a mobile health app quality rating tool, used on mental health primarily, to measure the quality of an app on engagement, functionality, aesthetics, and information quality, as well as app subjective quality. Using mars, the workgroup evaluated those resources that were aligned with the first two priority areas of the whos guideline: oral health literacy for the general public or training for dental or non-dental providers. This presentation will share the strengths and uniqueness of each resource to the audience as expert opinions and how those resources can promote oral health and oral health care experience. The presentation will also share non-english moral health resources, their concept, and how other countries can adapt to those models.

Support to responsive parenting through m-health

Svetlana Mladenovic Jankovic¹, Dusanka Matijevic¹, Gordana Tamburkovski¹, Aleksandra Andric¹, Marija Markovic¹, Nemanja Stefanovic¹, Andjelka Grujicic¹, Nevenka Kovacevic¹, Inga Mijailovic¹, Jelena Vasojevic¹, Aleksandra Vuckovic¹, Vladimir Glisovic¹, Svetlana Miltenovic¹

¹Institute of Public Health of Belgrade, Serbia

Background: Mobile applications on child health and development are available resource for improvement of parental capacities and promotion of positive family environment. Mob app "Bebbo" is comprehensive interactive guide for parents and offers different functionalities as daily reads, monitoring child development, reminder for preventive checkups and immunization, advices for stimulation

child development. The application was created based on the prototype of the application "Hello Baby - Your companion in parenthood" developed by UNICEF in Serbia and the Institute for Public Health with the Nordeus. The UNICEF regional office for Europe and Central Asia enabled the application to be improved and to cross the borders of Serbia and start living under the new, international name "Bebbo" in as many as 11 countries and territories, in 19 language variants. Objective of this paper is to present utilization of mobile application.

Method: Retrospective analysis of data on mob app utilization in Serbia between Oct 2021 and Nov 2022. Data were available through mob app statistics.

Results: More than 39000 users downloaded mob app from Play store and App store. Most of them are parents, mainly mothers of newborns and infants. Articles that raised most of the attention of users were about child development, nutrition and breastfeeding, health and wellbeing, immunization, play and learning, responsive parenting, safety and protection. Most popular games were about stimulation of motor development, language and communication, and socio emotional development. Most of users was interested in monitoring of child milestones, and less in measuring of child growth. Functionalities on child checkups and immunization has been also utilized.

Conclusion: The mobile application „Bebbo" was used by parents for various contents of importance for childrens health. Aspect of child development was most prominent through articles and functionalities most used. Data on mobile app utilization is important tool for further content management.

Health care risk assessment of the effectiveness and efficiency of COVID-19 remote patient telemonitoring

Chiara Parretti¹, Micaela La Regina², Paul Barach³, Riccardo Tartaglia¹

¹Department of Science Engineering, Marconi University, Rome, Via Plinio 44 00192 Rome, Italy, ²Healthcare Agency 5 La Spezia, Via Fazio, 30 La Spezia, Italy, ³Jefferson College of Population Health, United States

Background and Objective: The COVID-19 pandemic accelerated the spread of telemedicine (TM). The WHO stresses the importance of developing digital solutions with the goals of making care more effective, safe, and of better quality. While market forces are eager to drive innovation, problems with usability and intraoperability remain. We analyzed two TM applications in different Italian facilities. The objective was to highlight key gap areas of criticality, and to develop a proactive implemantation model to guide implementation of future effective telemedicine services.

Methods: We analyzed the inherent risks of TM using robust mixed methods, including failure mode and effects analysis (FMEA), a prospective, team-based risk management methodology structured to identify high-risk process system vulnerabilities and failures before they occur. We report on a remote patient monitoring (RPM) program in which 200 COVID-19 patients were followed remotely to evaluate the effectiveness in treating and monitoring patients in home settings. Results: We demonstrated that a telemedicine device reduced the number of hospitalizations and costs significantly. Assessment based on FMEA offers important insights and considerations for evaluating the future implementation of RPM and the direction of TM. Telemedicine solutions are technically feasible, easy for staff to use, achieving high adherence rates, but rigorous evaluation of devices and platforms is needed to clarify their value and guide optimal adoption strategies.

Conclusions: Telemedicine saved lives and improved decision making during the pandemic, helped prevent the collapse of the health care system, and had a positive impact on continuity of care, quality of life, and self-care. Integration of electronic medical records and telemedicine devices represents a compelling innovative solution that could greatly improve quality of care and lower the error rates. Rigorous and ongoing evaluation of devices and platforms is essential to clarifying their value and guiding national decisions and adoption programs.

A global adoption of cryptocurrency and blockchain technology; assessing the challenges of integrating digital coins and blockchain technology into the healthcare system

Teresa McKelvy¹, James Johnson¹, Steven Berkshire²

¹Central Michigan University, 1726 Victoria Ave., Berkeley, IL 60163, United States, ²Central Michigan University, The Herbert H. & Grace A. Dow College of Health Professions, 1280 E. Campus Dr., Mount Pleasant, MI 48859, United States

Background and Objective: To determine if cryptocurrency and blockchain technology can be leveraged to strengthen a hospital or private practices financial

position. We also want to establish if blockchain technology will provide a more secure mechanism for protecting patient records and payments.

Methods: Examined 34 global research and professional writings published between 2008 to 2022 to assess the future and recognize the potential of cryptocurrency and blockchain technology. Reports were analyzed using qualitative research methods.

Results: Dozens of medical cryptocurrencies/digital coins are already available to purchase and spend. Using cryptocurrency will provide a more secure decentralized payment platform that does not use third-party financial intermediaries. Adopting blockchain technology is a safe component of protecting payments and patient records. It uses cryptography that makes data modifications virtually impossible once recorded; it promotes fidelity, transparency, and security. Data can only be altered if you alter all subsequent blocks, which requires a consensus of the network majority. Blockchain technology also protects against ransomware attacks on healthcare providers and facilities. United Healthcare Group, Anthem, and Aetna are a part of a group to test blockchain technology. 55% of U.S. Executives plan on investing 1Mil USD in blockchain technology. Companies are creating EMR systems powered by technology to be prepared for adoption.

Conclusion: The evidence indicates an upcoming disruption in how we finance our office visits, co-pays, co-insurance, procedures, hospital stays, and prescriptions. It also suggests that cryptocurrency and blockchain technology in healthcare will become more mainstream within the next ten years. With common sense governmental intervention and the stabilization of the crypto market, cryptocurrency can augment the financial position of a hospital or private practice if appropriately managed.

Fluoride-related misinformation analysis on Twitter: Infodemiology study

Matheus Lotto¹, Zakir Irfhana², Jasleen Kaur¹, Zahid Butt¹, Thiago Cruvinel³, Plinio Morita¹

¹School of Public Health Sciences, University of Waterloo, Waterloo, ON, Canada, Canada, ²School of Public Health Sciences, University of Waterloo, Waterloo, ON, Canada, India, ³Department of Pediatric Dentistry, Orthodontics and Public Health, Bauru School of Dentistry, University of São Paulo, Bauru, Brazil

Background & Objectives: The presence of misinformation on social media significantly harms communities since accessing trustworthy information is a ground principle for people to achieve better health-related outcomes. In this context, anti-fluoridation content is broadly shared on social media, deceiving people about fluoride's relevance and safety. Considering the potential negative implications of online fluoride falsehoods, the present study aimed to analyze fluoride-related misinformation on Twitter.

Methods: First, 23,436 tweets were collected using the Twitter Application Programming Interface (API) from the keyword "fluoride-free" between May 2016 and May 2022. After data preprocessing, Latent Dirichlet Allocation (LDA) topic modeling techniques were applied with remain 21,169 tweets to determine the salient topics linked to the falsehood. Finally, time series decomposition methods were applied to define fluoride misinformation trends and seasonality over time using pandas, NumPy, and statsmodels.tsa.seasonal libraries in Python 3.

Results: From a coherence score of 0.542, a total of 3 different salient topics emerged from the LDA topic modeling analysis. As a result, fluoride-related misinformation was mainly associated with the people's perception of a healthy lifestyle (topic 1), followed by the consumption of natural and organic oral care products (topic 2), and recommendations of fluoride-free products and measures (topic 3). Notably, all topics displayed a decreasing trend between 2016-2019 and an increasing trend from 2020 onwards. Moreover, they presented a seasonal pattern of searches with peaks mainly at the beginning and middle of each year.

Conclusion: Fluoride misinformation was primarily related to personal concerns about a healthier lifestyle. The recent increasing trends of falsehoods have probably contributed to the popularization of fluoride-free products and the suspension of fluoridated water community programs. Hence, user-centered digital health strategies are required to control the spread and consumption of fluoride misinformation on social media.

Can the apple watch ECG app be successfully used for measuring stress?

Pedro Velmovitsky¹, Paulo Alencar¹, Matheus Lotto¹, Scott Leatherdale¹, Donald Cowan¹, Plinio Morita¹

¹University of Waterloo, 162 McGarry Dr, Canada

Background and Objective: Stress is a major public health issue correlated with severe health conditions, including depression, obesity, and cardiovascular diseases. Public health efforts typically are designed regarding the self-perceived stress of people. Interestingly, new advances in smart technology can support stress quantification, complementing traditional measurement methods. Hence, this study aimed to examine the prevalence of stress among the Canadian population using the Apple Watch ECG app.

Methods: Forty-one participants were invited to use an iPhone 7 and an Apple Watch 7 for 2 weeks to measure self-perceived stress and ECG metrics six times per day. The iPhone contained an app that collected ECG from Apple Watch and allowed participants to self-report stress through a questionnaire composed of the Depression, Anxiety, and Stress Scale (DASS-21) and a Likert-based scale question about self-perceived stress level. Both scales were dichotomized into non-stress and stress concerning a cut-off score of 14 points for DASS-21 and 2 points for the single item. Statistical analysis was performed using the Statistical Package for Social Sciences (v. 28.0). First, Heart Rate Variability (HRV) data were extracted from the ECG. Next, the data normality and homogeneity were determined using the Kolmogorov-Smirnov and Levene tests. Then, Mann-Whitney was used to compare HRV variables with self-perceived stress. For all analyses, P<.05 was considered significant.

Results: Several features were statistically significant, including the standard deviation of NN intervals (SDNN), the root mean square of successive differences (RMSSD), the heart's acceleration (AC) and deceleration (DC), and several high-frequency features.

Conclusion: Features widely used in HRV analysis (SDNN, RMSSD) proved statistically significant when measuring stress. In addition, AC and DC are relatively new indicators and lack research with a focus on stress, suggesting new avenues of research. Ultimately, the results support using the Apple Watch ECG to study stress.

Telemedicine in the monitoring of covid-19 patients: general practitioners' usage, facilitators and barriers in the local health authority roma 1

Andrea Barbara¹, Leonardo Villani², Paolo Lombardo¹, Paolo Parente³, Antonella Gemma³, Lavinia Barone¹, Fabiano Grassi⁴, Mauro Goletti³, Enrico Di Rosa³, Corrado De Vito¹

¹Department of Public Health and Infectious Diseases, Sapienza University of Rome; ²Local Health Authority Roma 1. Italy, ³Department of Hygiene, University Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy, ⁴Local Health Authority Roma 1., ⁴Department of Public Health and Infectious Diseases, Sapienza University of Rome

Background and Objective: Telemedicine is a powerful tool for managing of COVID-19 patients.

Our study aims to evaluate the use, barriers and facilitators of the "Lazio ADVICE" telemedicine platform according to General Practitioners (GPs) and Family Paediatricians (FPs) of the LHA Roma 1 to contrast the pandemic. This could be useful for the wider implementation of telemedicine in primary healthcare.

Methods: We performed an interview-based survey composed of questions investigating the demographic information of GPs/FPs, the knowledge of the platform, frequency of utilization, usefulness, strengths and weaknesses and the hypothesis of future implementation proposed.

Results: We interviewed 214 physicians (21.75% of the total population): 89 (41.59%) users and 125 (58.41%) non-user. Older age and working in District 1, 14 and 15 (vs. District 13) significantly reduced the probability of using the platform by the physician.

Among the users, 19 (21.35%) used the platform every day or even several times a day, 40 (44.34%) several times a week but less than one access per day, 30 (33.71%) several times a month. Most of them (92.26%) consider the platform useful. Suggested improvements: integration between physician's applications (86.26%), presence of data regarding COVID-19 diagnosis and contact tracing (69.6%), facilitating access and usability (52.81%). Difficulties: poor integration among software and work routine (76.4%), deficiencies regarding contact tracing (67.41%), access and usability issues (53.93%).

Among the non-users, 14 (11.2%) didn't know the platform existence, 60 (48%) never tried and 51 (40.8%) tried to use it. Reported reasons for the interruption of use were: not very user-friendly (45.1%), perceived useless (37.26%), non-optimal functioning (23.53%) and lack of time (19.61%).

Conclusion: The COVID-19 pandemic has accelerated the implementation of

telemedicine services. Telemedicine for monitoring patients has potential but certainly, to be competitive it must offer something different or additional than telephone consultation.

Digital divide older adults' approach to digital health: an integrative review

Elisabetta Corvo¹, Walter De Caro²

¹Canterbury Christ Church University, United Kingdom, ²CNAI Italian Nurses Association, Italy

Introduction: There is a growing use of in primary and secondary care facilities of digital health in terms of receiving exam results, repeating prescriptions, health promotion, and disease prevention. There is a general agreement in the literature that this approach is cost-efficient and time efficient for National Health Systems, specific health facilities, and, more generally, for individuals' health. Due to the demographic change in Europe, there is a high number of older people.. The introduction of technology to improve health promotion and health care provided to citizens must be balanced by a sufficient level of participation and use of the technology itself by all citizens, especially by those who potentially have the most need (older adults).

Methods: This integrative review aims to identify the state of the arts across Europe regarding access, use, and confidence in using digital health technology by older people (65+). Three central databases have been interrogated: Pubmed, Cinhal, and EMBASE in the last 5 years. Inclusion criteria were research carried out in English, focused on older people above the age of 65.

Results: The results displayed a frustration perceived by older people in using these tools of which they recognize the usefulness but at the same time need to have perfect mastery. Results show a general difficulty for older people to access hospital portals, due to a need for digital and health literacy and a general lack of confidence about privacy and security in disclosing their data on the internet.

Conclusion: If, on the one hand, these technologies have demonstrated value in the management of some illnesses and in facilitating the patient-health system relationship, these mustn't become a barrier to adequate access to care which is a social determinant of health. A process of education and support for older people should be implemented.

DOI: 10.18332/popmed/163878

A systematic review of conversational artificial intelligence for smoking cessation

Hollie Bendotti¹, Henry Marshall², Sheleigh Lawler³, Coral Gartner⁴, David Ireland⁵

¹The University of Queensland, Thoracic Research Centre, Faculty of Medicine, Australia, ²The Prince Charles Hospital, Queensland Health, ³The University of Queensland, School of Public Health, Faculty of Medicine, Australia, ⁴The University of Queensland, NHMRC Centre of Research Excellence on Achieving the Tobacco Endgame, School of Public Health, Faculty of Medicine, Australia, ⁵The Australian e-Health Research Centre, Commonwealth Scientific and Industrial Research Organisation

Background: Conversational artificial intelligence (AI) (chatbots, dialogue systems and virtual agents) is an emerging tool for tobacco smoking cessation which has the potential to emulate personalised human support and increase engagement. We aimed to determine the effect of conversational AI interventions with or without standard smoking cessation interventions on smoking cessation outcomes among adults who smoke, compared to no intervention, placebo intervention or an active comparator.

Methods: A comprehensive search of six databases was completed in June 2022. Eligible studies included randomised controlled trials (RCTs) published since 2005. The primary outcome was sustained tobacco abstinence, self-reported and/or biochemically validated, of at least 6 months. Secondary outcomes included point-prevalence abstinence, sustained abstinence of less than 6 months. Data extraction of cessation outcomes and risk of bias assessments was completed independently by two authors.

Results: Five RCTs met inclusion criteria (n=58,796) from 819 studies; all differing in setting, methodology, intervention, participants and endpoints. Conversational AI interventions included chatbots embedded in multi- and single component smartphone apps (n=3), a social media-based (n=1) chatbot, and an internet-based avatar (n=1). Random effects meta-analysis found participants in the conversational AI enhanced intervention were significantly more likely to quit smoking at the end of the trial compared to control group participants (RR = 1.61, 95% CI (1.21, 2.13), p = .001). High heterogeneity was found between studies

(Q(4) = 53.84, p<.001), as well as high overall risk of bias. Loss to follow-up was generally high.

Conclusion: There is limited but promising evidence on the effectiveness of conversational AI interventions for smoking cessation. While all studies found benefit from conversational AI interventions, substantial heterogeneity means the results should be interpreted with caution. Given the rapid evolution and potential of AI interventions, further well-designed RCTs are warranted in this promising area.

Evaluation of data management systems for COVID-19 vaccine rollout in Australian health systems: a public health perspective

Bret Gutierrez¹

¹The University of Melbourne, Melbourne School of Population and Global Health, E. Rodriguez Sr., Ave., Quezon City, Philippines

Vaccination is one of the greatest breakthroughs in public health and remains one of the best weapons against infectious diseases. Health Information Systems (HISs) are cloud-based, population-focused and confidential public health platforms that aid the COVID-19 vaccination programme at Northern Health Australia. They established their own HIS on vaccination while CVMS was being developed. This paper uses the RE-AIM (Reach, Effectiveness, Adoption, Implementation and Maintenance) framework, based on continued involvement in the implementation of two immunisation information systems: COVID-19 Vaccination Management System (CVMS) and the in-house Northern Health System (NHS). Through engagement with various stakeholders, the author established analytical frameworks, a logic model and HIS documentary analysis from a public health perspective with an emphasis on three major HIS utility parameters. The key findings are (1) vaccination information systems promote vaccine equity among populations, (2) information systems promote improved decision-making of clinicians and government, which strengthens the health system and (3) vaccination information systems evaluate the safety and effectiveness of vaccines. Despite the challenges, the two immunisation HIS are instrumental in improving vaccination-related activities from managing and consolidating data in the booking system, AIR data compliance and adverse events reporting, are used to guide policymakers and further support public health emergency decision-making. The ideal system would centralise data exchange, submission and analysis across the whole state, provide easy accessibility to the public, and promote coordination between stakeholders for continuous improvement. However, it is worth noting that balancing requirements while setting up these large systems may imply a longer development time.

DOI: 10.18332/popmed/163913

Digitize to reach and track: An retrospective analysis of digitalized immunization data for children under one year in Bangladesh from Pre-COVID and during-COVID era

Avijit Saha¹, Mahub Latif², Md. Hossen³, Zahid Hasan⁴, Malabika Sarker¹

¹BRAC James P Grant School of Public Health, BRAC University, 6th Floor, Medona Tower, 28 Mohakhali Commercial Area, Bir Uttom A K Khandakar Road, Dhaka-1213, Bangladesh, ²Institute of Statistical Research and Training (ISRT), ³EPI & Surveillance, EPI, DGHS, MoHFW, Bangladesh, ⁴UNICEF Bangladesh, United Nations Children's Fund, UNICEF House, Plot # E-30, Syed Mahub Morshed Avenue, Sher-E-Bangla Nagar, Agargaon, Dhaka-1207, Bangladesh

Introduction: With an impressive track record in expanding childhood immunization and an inclination to adopt digitalization in healthcare service delivery, Expanded Program on Immunization (EPI) Bangladesh piloted the e-Tracker intervention in Moulavibazar district and Dhaka South City Corporation (Zone-5) from 2019 till the end of 2021.

Objective: We analyzed the digitalized e-Tracker data intending to calculate vaccination coverages, dose timeliness, and dropout rates for children under one year of age from Pre-COVID and during-COVID era to aid with informed decision-making by the policymakers.

Method: With help from Health Management Information System (HMIS) and UNICEF Bangladesh, we retrieved e-Tracker data for infants born between January 1, 2019, and December 31, 2021. Childhood vaccination coverage and dropout rates were determined using a Traditional approach traditionally used by WHO and a Conditional technique with a modified denominator. Using a multivariate logistic regression model, we examined the relationship between vaccination rates and birth cohorts, mother education, and location.

Result: The conditional estimation yielded a lower full vaccination coverage

(68.7%) than the national (from aggregated data, 89.0%) and global coverage (81.0%). Coverage and dropout rates increased more during the 'during-COVID' era than in the 'pre-COVID' period. However, dropouts were estimated lower in the 'conditional method'. The average age (in months) for getting BCG was higher in Moulavibazar (~2.5 months) than that in Dhaka (~1.4 months). All child birth-cohorts from 'the during-COVID' era had about a 30% lower chance of getting fully vaccinated than those from the 'pre-COVID' era.

Conclusion: Age-cohort-specific studies showed a reduction in coverage estimates before and after COVID, but e-Tracker didn't have enough data to draw additional conclusions. The server only stored the child's gender, the caregiver's monthly salary, and the mother's education. It didn't track the dropout factors or if families departed pilot regions. Future updates and system expansion should help.

DOI: 10.18332/popmed/163951

Changing dimensions in immunization: Implementation research on the E-tracker intervention for improving vaccination of children in Dhaka and Moulvibazar, Bangladesh

Humayra Anwar¹, Saima Mehjabeen¹, Avijit Saha¹, Md. Hossen², Md. Islam Fuad³, Zahid Hasan⁴, Md Hossen Shahed⁴, Malabika Sarker¹

¹BRAC James P Grant School of Public Health, BRAC University, 6th Floor, Medona Tower, 28 Mohakhali Commercial Area, Bir Uttom A K Khandakar Road, Bangladesh, ²EPI Bangladesh, Directorate General of Health Services, EPI Headquarter, Mohakhali, Dhaka, Bangladesh, Bangladesh, ³EPI Bangladesh, Directorate General of Health Services, ⁴UNICEF Bangladesh

Background: Achievement in the national Expanded Programme on Immunization (EPI) is globally recognized as an example in Low- and Middle-Income Countries (LMICs). However, the 2019 Coverage Evaluation Survey (CES) shows that 84% of children are fully vaccinated nationally. Digital solutions like mobile phone help reduce vaccination program challenges. Therefore, Bangladesh has been implementing a pilot intervention of individual electronic tracking (e-tracking) of children in Moulvibazar District and Dhaka South City Corporation and planning to scale it up.

Objective: The current implementation research was conducted to understand the implementation process, success, and challenges of the e-Tracker system in Bangladesh and obtain lessons learned and scaling-up recommendations.

Methods: The study followed the embedded mixed-method design, including both beneficiaries and implementers. This study occurred in selected areas of Moulvibazar District and Zone-5 of Dhaka South City Corporation and lasted from 1st April to 30th June 2021. A secondary analysis of existing vaccination coverage data of both the e-Tracker and the paper-based system was performed. Data were analyzed using Re-AIM Implementation Framework.

Results: According to the implementors, they get individual accurate coverage data, minimize dropouts, avoid mistakes, monitor, and recognize invalid doses from a single device. The caregivers receive SMS reminders of the child's vaccination date, yet many reported not receiving the SMS regularly. The frontliners, mostly from urban were comfortable using the e-Tracker app; however, the ageing rural field workers initially struggled to use the device. The e-tracker system creates additional load and requires regular troubleshooting and will require regular internet support and technical staff, especially from the government.

Conclusion: This study found that the e-Tracker can produce accurate real-time data and identify dropouts; however, we need technology friendly manpower, feasible technology, the uninterrupted internet, and logistics support with a sustainable maintenance mechanism to implement and scale up this technology-dependent intervention successfully.

³Cooperazione paesi emergenti, COPE NGO, Nyololo, Tanzania, ⁴Terre

innovative Healthcare s.r.l., Catania, Italy, ⁵Department of Public Health,

AUSL Modena, Modena, Italy, ⁶Service d'obstétrique - Département de la

femme, de l'enfant et de l'adolescent - Hôpitaux Universitaires de Genève,

Genève, Suisse; Takemi Program in International Health, Harvard T.H. Chan

School of Public Health, Boston, USA, Swaziland

Background and Objective: Antenatal care (ANC) is an essential component of women's reproductive health. Many women face difficulties in attending high-quality ANC visits for a positive pregnancy experience in low/lower-middle countries, such as Tanzania. Information and Computer Technologies (ICTs) are part of the core solutions for bridging the coverage and quality gap in health care. PANDA (Pregnancy And Newborn Diagnostic Assessment) is a mHealth system that incorporates WHO recommendations for ANC. This study aimed to assessing the effectiveness of PANDA system in provision of high-quality ANC in Mufindi district, Tanzania.

Methods: A cluster-based non-randomized interventional trial were performed from June 2019 to September 2020 to compare the quality of ANC visits by using PANDA system in the intervention site with standard visits conducted in the control site. We enrolled pregnant women attending at analogous health facilities in both sites. The indicators used to assess the ANC quality were: performed measurements and screening tests (syphilis, HIV, malaria, hemoglobin, glucose, height/weight, blood pressure, temperature, fetal movement, fundal height, urine dip stick), and prophylaxis provided for malaria, anemia and intestinal worms. Data Analysis was done using SAS version 9.4.

Results: A total of 597 pregnant women at the implementation site and 398 at the control site were enrolled. Most of them were in the age group 25-34 years (44.0%) and 15-24 (42.3%). The majority (60.8%) had more than one pregnancy. In the implementation area a significant higher coverage of performed screening tests and provided prophylaxis was recorded compared to the control area except for malaria prophylaxis. The provision of mebendazole and iron/folic acid was significantly higher in the intervention site.

Conclusion: PANDA system has been shown effective in providing ANC according to WHO recommendations for a positive pregnancy experience. We recommend the mHealth solution for bridging the quality gap in low/lower-middle income countries.

Mortality and Adverse Health Outcomes Associated with Telehealth: Systematic Review and Meta-Analysis

Fidelia Cascini¹, Paul Barach², Walter Ricciardi¹

¹Università Cattolica del S. Cuore, Italy, ²Thomas Jefferson University, United States

Background: The COVID-19 pandemic's contagion has forced healthcare to use telehealth. Evidence shows significant risks of telehealth use and potential issues that could compromise patient safety and decrease quality of care. This study aims to systematically review telehealth interventions assessed by randomized controlled trials (RCTs) and their effects.

Methods: We searched for randomized controlled trials of interventions to patients that received any type of telehealth tool as an intervention and compared it with a control group that also reported outcomes. We searched for PRISMA guideline English-language studies published until March 2021 in multiple databases including PubMed, Embase, and Scopus. Studies were categorized according to methodological quality, sample size, intervention characteristics, outcome, statistical significance, and direction of effects. A meta-analysis of sufficiently homogenous studies was conducted after quality assessment and data extraction.

Results: Of the 5,144 articles identified, 78 were included in the review. 8 were chosen to perform 2 separate meta-analyses (n=4 for each). The first assessed mortality rate in heart failure patients, showing the pooled relative risk of mortality to be 0.60 (95% CI, 0.0999-3.5478), p=0.42. The second assessed mortality in patients with cardiac implants: the pooled relative risk of mortality was 0.65 (95% CI, 0.4389-0.9541), p=0.028. Pooled qualitative assessment of the remaining studies was performed, producing two groups: telerehabilitation and miscellaneous studies.

Conclusions: The results suggest that monitoring patients using telehealth techniques is associated with 40% lower mortality risk among patients suffering from heart failure or cardiac implants, compared to those who received traditional care methods. Telerehabilitation was observed to be comparable with the conventional rehab methods. Telehealth applications that manage chronic disease resulted in lower or comparable mortality rates and hospitalization/re-admission rates. Cognitive behavioral and online psychotherapy show promise as alternative to conventional methods. Telehealth should be considered a safe alternative to traditional medical procedures.

Popul. Med. 2023;5(Supplement):A600

DOI: 10.18332/popmed/164023

Preliminary results from a multi-country survey investigating citizens' attitudes towards personalized medicine and data sharing

Francesco Causio¹, Carla Van El², Stefania Boccia¹, Flavia Beccia¹, Roberta Pastorino¹

¹Università Cattolica del Sacro Cuore, Italy, ²Amsterdam University Medical Center, Netherlands

Background and objectives: Personalized medicine is defined as a medical model that aims to provide tailored prevention and treatment to individuals, potentially impacting healthcare systems worldwide. Nonetheless, it requires healthy citizens to share their health data to assess their health status correctly. With this survey, we investigate the attitudes of citizens in different EU countries towards personalized medicine and data sharing.

Methods: Through the YouGov platform, we distributed an online 30-question survey to citizens from 8 EU countries (Italy, the Netherlands, France, Germany, Spain, Hungary, Romania, and Poland). Inclusion criteria were 18 years of age or above, citizenship in an EU country, and living in an EU country. Participants not satisfying any of these criteria were excluded.

Participation was voluntary and unpaid. The survey was divided into four sections: Knowledge and opinions on personalized medicine and genetic tests, Data use and sharing, Personalized medicine governance, and Citizens' needs. The performed statistical analysis is descriptive and comparative, including univariate tests (T-Test, Mann-Whitney test, chi-squared test). The STATA 16 software is used to perform statistical analysis. P significance threshold was set at < 0.05 .

Results: 6500 citizens from 8 EU countries participated: 1000 from Italy, 1000 from Germany, 1000 from France, 1000 from Spain, 1000 from the Netherlands, 500 from Hungary, 500 from Romania, and 500 from Poland. Participants were spread evenly among the age range 18-99. Detailed statistical analysis is still ongoing, but preliminary results show attitudes to be more favorable in younger generations. In contrast, older people are generally more hesitant to share data for health purposes.

Conclusion: Personalized medicine can potentially change the classical medical paradigm of diagnosis-treatment towards a prevention-oriented system. Notably, an approach that considers people's opinions is needed. Our work addresses this issue in detail with a multi-country approach.

Feasibility of telemedicine in anaesthetic preoperative evaluation: the organisational management experience of a teaching hospital in Italy

Martino Godoy¹, Daria Bucci¹, Manuel Stocchi¹, Giorgio Marra², Federico Esposti², Carlo Signorelli³

¹Università Vita-Salute San Raffaele Italy, ²San Raffaele Hospital Italy,

³Università Vita-Salute San Raffaele, San Raffaele Hospital Italy

The COVID-19 pandemic highlighted the essential role of remote healthcare solutions, following the isolation rules forcing the loss of follow-ups, thus implying a worldwide growth of disease burden and costs for health systems. This need turned into an opportunity as telemedicine is now - post-pandemic - an essential tool to lighten the pressure on hospitals and healthcare facilities, to ease health-related processes for both patients and physicians, to reduce possible complications implied by people aggregations in these structures, without reducing the overall quality of healthcare. San Raffaele Hospital was the first Italian hospital to provide a free telemedicine platform in 2020. We aimed to report the advantage of digitalisation, extend telemedicine to the preoperative anesthesiological evaluation in minor surgeries, and assess patient and hospital-related outcomes to create a framework pattern. A literature review was performed to retrieve the state of knowledge, but Italy lacked real-life applications. This framework aimed to be faster and more patient-friendly, avoiding wasted resources and the overloading of surgical waiting lists. Our pilot was meant to raise awareness on the topic and, as future perspectives, extend the pool of pre-surgical evaluations accessible by telemedicine. From the end of 2021, we started reconstructing the hospital's clinical and administrative preoperative pathways. We recruited an anesthesiologists team and started screening surgeries where preoperative evaluation could be led through remote consultation, therefore creating a framework proposal. Piloting this new process, surgeons freely enrolled patients, explaining the role of telemedicine in the preoperative procedure. A hospital administrative team accomplished the patients' chart creation on the platform and followed-up the steps completeness. Patients were requested to upload previous medical records and fill out an anesthesiological survey. Surgery-specific routine screening exams were provided before the video-visit evaluation; further investigations were eventually requested. When anesthesiological fitness was reached, patients could be hospitalised for surgery.

Identification and classification of tobacco-promoting social media content at scale using deep learning: a mixed-methods study

Hüseyin Küçükali^{1,2}, Mehmet Sarper Erdoğan¹

¹Department of Public Health, Istanbul University - Cerrahpasa, Istanbul,

Türkiye, ²Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom

Background and Aim: Marketing activities of the tobacco industry on social media as an escape area have become salient in recent years. Whether its commercially motivated or not, exposure to tobacco-promoting content on social media is shown to influence subsequent tobacco use. Artificial intelligence technologies may help tackle this problem where existing policies and tools are insufficient for timely primary prevention. This study aims to develop an artificial intelligence powered tool that can automatically identify and classify tobacco-promoting content on social media.

Methods: This study is designed as a sequential mixed-methods study where qualitative analysis preceded quantitative one. A probabilistic sample ($n=5000$) from tobacco-related tweets that are published on Twitter in October 2020 ($n=177,684$) is selected. Four major tobacco-promotion mechanisms were identified inductively by qualitative content analysis. 27 trained volunteers deductively coded tweets into four mechanisms. The labelled dataset was used in supervised machine learning to finetune a pre-trained transformer-based language model (BERT) in multiple scenarios. The performance of predictions was compared with human coders. High-performing models predicted the tobacco promotion status for all tobacco-related tweets collected.

Results: Tobacco promotion in social media content was predicted with a recall of up to 87.8% and precision of up to 81.1%. The mean number of tobacco-promoting tweets per day was 2360.1 ± 599.4 and they constituted 39.8% of all tobacco-related tweets. Tobacco promotion was more frequent among tweets that are original, mentioned by another user, published at the night, and from a mobile device.

Conclusion: We developed an "inveillance" tool that makes it possible to monitor tobacco-promoting social media content near real time. This tool may strengthen tobacco control policies and create new opportunities for health promotion practice.

DOI: 10.18332/popmed/164106

A Scoping Review of the Existing Telemedicine Applications in India: Learnings for the Future

Vanita Singh¹, Vanita Singh¹

¹Management Development Institute, Gurgaon, India

Background: Countries, including India, were quick to adopt telemedicine for delivering primary care in response to the widespread disruptions in routine healthcare delivery due to COVID-19 pandemic. This expeditious adoption was critical and the challenges faced during this exigency could guide the design and delivery of future telemedicine applications for primary care delivery.

Methods: With an aim to identify challenges in delivering primary care via telemedicine technology in Indian context a scoping review was conducted using popular medical database (PUBMED) and largest database of peer-reviewed literature (SCOPUS). Drawing from the systems approach in healthcare delivery, the review findings challenges are summarized at four levels, patient, provider, healthcare organizations, and, policy.

Results: Out of the 247 search results, 13 articles met our inclusion criteria. This review highlighted that telemedicine facilitated continuity of care during COVID-19 but not without challenges. Low levels of education and computer literacy along with language barrier posed challenges at patient level. Providers were challenged due to limited skills in using systems, and had concerns related to efficiency and effectiveness of remote consultations, legal liabilities, and unethical behavior of patients. The healthcare delivery system faced challenges in ensuring an integrated care as there was lack of integration with diagnostics, pharmacies, and other departments. The current policy landscape falls short in addressing data privacy and security concerns, unethical behavior by patient, or provider, and regulating prescriptions of psychotropic drugs.

Conclusion: Telemedicine has the potential to improve primary healthcare delivery and address health system challenges even beyond COVID-19. The reviewed telemedicine applications in India mirrors the existing fragmented healthcare delivery system. There is a need to acknowledge and factor-in the inter-connectedness of health system elements and organize health system elements

facilitating an integrated care approach via telemedicine thereby ensuring an effective and efficient healthcare delivery via telemedicine.

Artificial Intelligence for social media monitoring of attitudes towards COVID-19 vaccination: a scoping review

David Rocchi¹, Alessandro Berionni², Luigi Angelis¹, Francesco Baglivo¹, Andrea Causio³, Angela Ancona⁴, Valerio Corona³, Virginia Casigliani¹, Marta Caminiti⁵, Caterina Rizzo¹

¹University of Pisa Italy, ²Università Vita Salute San Raffaele Italy, ³Università Cattolica Sacro Cuore Roma Italy, ⁴Università Vita Salute San Raffaele, ⁵University of Perugia Italy

Background and Objective: Social media were crucial in spreading vaccine hesitancy during the COVID-19 Pandemic. Social media monitoring of vaccine stances can be extremely useful to identify trending topics and adapt communication strategies. The objective of this scoping review is to explore the use of Artificial Intelligence (AI), Such as Natural Language Processing (NLP), in social media monitoring, on the topic of vaccine stance and intent related to COVID-19 vaccination campaigns. **Methods:** The study was conducted in november 2022 on multiple databases, using the pico framework. A search query identifying mesh terms for pubmed was developed and adapted for scopus and web of science databases. The study included only english papers, published during the last 3 years, that specifically addressed ai methodologies, social media and vaccine stance. Search results were uploaded to rayyan, a collaborative web application for systematic reviews, to automatically identify duplicates. All studies identified were screened by five authors using article titles and abstracts. Further steps are ongoing.

Results: A total of 2,722 results were found on pubmed, 5,230 results on scopus, 3,304 results on web of science. After clearing out the duplicates, 5,674 articles were included for title and abstract screening. Among identified ai methodologies, nlp solutions extracting information from tweets were the most frequently identified. Sentiments identified among different studies were discouraging towards vaccination in 20% of the tweets. Further results will be available after the initial and full-text screening to reach a total of a few tens of articles.

Conclusion: This review shows the opportunity to apply AI methodologies to social media monitoring regarding COVID19 vaccine stance. Despite the frequent use of NLP, many different machine learning methodologies are reported in the screened articles, which combined with the growing amount of existing social-media, leads to a great heterogeneity in AI-based social media monitoring.

¹IRCCS Istituto Clinico Humanitas Via Alessandro Manzoni, 56, 20089

Rozzano MI Italy, ²IRCCS Istituto Clinico Humanitas Italy

Background and Objective: The COVID outbreak has required many person-hours of infection control and occupational health personnel within hospitals to identify the community or nosocomial origin of the infection, as well as case contacts between patients and healthcare professionals. Furthermore, nosocomial COVID represents a care-related infection and, as such, it can be one of the causes of complaints and/or requests for compensation by patients and caregivers.

Having a rapid and reliable system for identifying the origin of COVID cases has the following advantages: The reduction of the commitment of dedicated healthcare personnel; Early identification of cases with possible image damage or medico-legal implications; The definition of an internal and external benchmark.

We tried to develop an algorithm that distinguished community, probably community, probably nosocomial, and nosocomial COVID cases, adapting the case definitions by the source of infection published by ECDC.

Methods: The following information was extracted from the electronic health records: Type of hospitalization: urgency, elective; Date of admission; Positivity date for 1st positive test for COVID;

Based on that, the algorithm has assigned the different COVID+ cases to one of the 4 categories. The algorithm, validated by infection control personnel, was then implemented.

Results: The validation of the algorithm carried out on a n. 65 of COVID+ cases showed an initial per cent agreement of 56.9 %. The different attribution of the category was initially found for probably community cases, whose correct identification was facilitated by the graphical interface of the application.

Conclusion: automatic methods for defining cases on parameters that are easily identifiable in the electronic health records can be an effective low-cost analysis tool with a high impact on the organization of the hospital staffs time

commitment, as well as a tool to support daily clinical activity and medium-long term business planning.

Fostering exchange of genomic data between European countries for clinical and research purposes: the genomic data infrastructure (gdi) project

Stefania Boccia¹, Flavia Beccia¹, Giovanna Calabrò¹, Roberta Pastorino¹, Giovanni Comandé², Domenico Coviello³, Marco Morelli¹, Graziano Pesole¹, Giovanni Tonon¹, Francesco Causio¹, Sara Farina¹, Luigi Russo¹, Andriy Melnyk¹, Serena Scollen⁴

¹Università Cattolica del Sacro Cuore Italy, ²Scuola Superiore S. Anna Pisa Italy, ³Istituto Gianna Gaslini IRCCS Italy, ⁴Elixir United Kingdom

Background and Objectives: Since 2018, 24 EU countries, the UK, and Norway joined the One+ Million Genomes initiative (1+MG) to step up efforts towards creating a European data infrastructure for genomic data and implementing common national rules enabling federated data access. The goal is to ensure appropriate technical infrastructure is available to allow for secure, federated, and ethically sound access to genomic data. In the first phase, the "Beyond 1 Million Genomes" (B1MG) project dealt with infrastructure set-up, legal and technical guidance, data standards, and best practices to enable data access.

Methods: The Genomic Data Infrastructure (GDI) project was launched in November 2022 to start the scale-up and sustainability phase of the 1+MG initiative. It includes 44 partners from 20 countries, divided into 8 Work Packages across three pillars (Long-term sustainability, 1+MG infrastructure, and Application and innovation solution).

Results: Over 4 years, the GDI project will establish a federated data infrastructure across Europe for genomic and clinical data. It will also design and implement a communication strategy to inform citizens and policymakers and ensure their trust.

Conclusion: The GDI project will provide data access and governance to genomic and clinical data across adhering countries, integrating them and making them available for clinicians and researchers safely and sustainably.

Improving the effectiveness of telemedicine in rural communities: reflecting on client and provider experience of esanjeevani jharkhand

Aditya Naskar¹, Shilpa Bhatte¹, Neha Verma¹, Amit Parab¹, Rajeev Kumar¹, Shivshankar Kumar¹, Ashok Tigga¹, Praveer Mahto¹, Sanjay Kumar², Shyamal Santra¹, Lalit Pathak³

¹Intelehealth India, ²Transforming Rural India Foundation India, ³National Health Mission, Jharkhand India

Background: Recently, the government of jharkhand has adopted a web-based comprehensive telemedicine platform – named esanjeevani – to provide specialist healthcare consultations in rural areas. Under this program, rural health and wellness centers (hwcs) are upgraded to enable teleconsultations by connecting patients to remote doctors through audio or video calls.

Objective: To identify processes and enablers of improving outcomes of telemedicine services under esanjeevani with respect to patient-reported outcomes, acceptability of telemedicine among providers and clients, and their perceptions on service delivery.

Methods: A mixed method approach was used combining cross-sectional surveys and qualitative interviews with clients and providers. 500 clients and 119 health providers across five districts were surveyed, and in-depth qualitative interviews were conducted with 10 health providers and 20 clients. The analysis is guided by the implementation research framework suggested by the medical research council to identify processes and facilitators integral to shaping outcomes.

Findings

The findings indicate that esanjeevani is perceived as an affordable and easily accessible health service delivery platform – with clients emphasizing a reduction in health expenditure and improved provider availability. Overall, we estimate that telemedicine saved 21.59 km in distance traveled and inr 941.51 per health visit. Community health officers and frontline workers were identified as the primary drivers of the intervention. providers also reported a high level of acceptability in terms of perceived usefulness and ease of use and highlighted the need for continued capacity building and behavior change to increase the adoption of the platform.

Conclusion: The esanjeevani program has been effective in providing affordable quality specialist consultation to patients in rural communities, especially women.

However, there are a few challenges such as the need for improvement in reducing over-referrals, creating community demand, capacity building of the telemedicine workforce, and challenges related to deficits in digital infrastructure in rural contexts.

DOI: 10.18332/popmed/164253

An exploration of mothers' and fathers' perspectives on a mhealth application to support parents in the first 1,000 days of life

Laura Brunelli¹, Sofia Bussolaro¹, Raffaella Dobrina², Chiara Vita¹, Elena Mazzolini¹, Giuseppa Verardi², Maura Degrassi², Maria Piazza², Andrea Cassone², Anja Starec³, Giuseppe Ricci⁴, Sara Zanchiello³, Tamara Stampalija⁴

¹Department of Medical, Surgical and Health Sciences, University of Trieste, Trieste, Italy, ²Healthcare Professions Department, Institute for Maternal and Child Health - IRCCS "Burlo Garofolo" - Trieste, Italy, ³Area Science Park, Trieste, Italy, ⁴Department of Medical, Surgical and Health Sciences, University of Trieste, Trieste, Italy; Obstetrics and Gynecology Clinic, Institute for Maternal and Child Health - IRCCS "Burlo Garofolo" - Trieste, Italy

Background and objective: The first 1,000 days of life play a crucial role in the child's health and development. However, existing mHealth solutions often provide unreliable information about this critical period, without considering the real needs of parents and, worse still, usually neglecting fathers. We explored the information needs of both parents for a hypothetical mobile application to support the first 1,000 days.

Methods: Between May and August 2022, we enrolled new and expectant parents attending an Institute for Maternal and Child Health in north-eastern Italy in a cross-sectional study. We administered a 39-item questionnaire on a 5-point Likert scale (0-not important at all; 4-absolutely essential) to assess the importance of a set of content about pregnancy and postpartum provided by the proposed application. Based on mean scores (M±SD), items with ratings greater than or equal to 3.5 were identified as top ranked items related to priority content.

Results: Priorities differed between mothers (n=94) and fathers (n=69). Five of the six top ranked items for fathers were related to "pregnancy", including general information about pregnancy (3.7±0.6), information about possible infections (3.6±0.7), examinations to be performed (3.5±0.7), and delivery (3.5±0.7). Conversely, six of the nine top ranked items for mothers fell into the "postpartum" domain, including information about neonatal complications and warning signs (3.7±0.9), tips for the postpartum recovery process (3.5±0.8) and newborn care (3.5±0.7), information on breastfeeding practices (3.5±0.9), neonatal screening procedures (3.5±0.8), and risk prevention measures related to the newborn (3.5±1.1).

Conclusion: Overall, the fact that fathers focus on pregnancy might indicate that they are more "unprepared" for this phase compared to mothers who are ready to face the postpartum period. Valuing the different perspectives of mothers and fathers is essential to develop mHealth solutions that promote gender-equitable family empowerment to deftly navigate the first 1,000 days of life.

Improving vaccine distribution on the "last mile" or in complex challenging situations

Coli MacDougall-Hunter¹, Uwe Winnwa²

¹Hunter Global Tracking Ltd, ²Out Task AG

Background and objective: Cold chain logistics still frequently stops at the final distribution centre before embarking on the tough 'last mile/low-income settings'; more rudimentary transport takes over (human, donkey, bicycle, drone, SUV). Recent WHO/UNICEF and independent reports sounded alarms as June 2022 data show global vaccination coverage continued to decline in 2021: 25 million infants missing out on lifesaving vaccines, due in part to supply-chain unavailability/disruptions that damaged at least 25% of vaccines (some cases up to 80% potency loss, the largest sustained decline in childhood vaccinations in approximately 30 years). In places of complex challenges around delivery (infrastructure, climate, floods, civil/ military conflicts, ...), the objective is to progressively improve vaccine distribution – hence vaccine potency and overall impact by introducing innovative but inexpensive technologies, to reduce waste, inefficient deliveries, theft, fraud.

Methods: 2 simultaneous on-going levels:

*equip any carrier fleet, current and future, for position tracking and content status monitoring with basic robust IoT labels/tracking systems, avoiding manual data capturing, providing transparency of current 'invisible' units.

*introduce an active, rugged, compressor-based, self-refrigerating/autonomous,

IoT-smart Cold Box/vaccine carrier, powered by solar and battery, with IoT components/sensors; currently under development; PoC pending WHO Certification.

* Trials/evaluation of transport 'last mile' by Health Authorities, vaccination programmes.

Results: expected:

* massive increase of live data enabling analysis of deficiencies, hence remedies;

* reverse sample logistics becomes possible;

* overall vaccine potency increases dramatically;

* paradigm shift from random short-term to long-term controllable mobile cooling units.

Conclusion: implementation of both aspects - upgrade of 'invisible' vaccine carriers and introduction of active, smart, carriers will significantly extend 'last mile' or 'broad use' vaccine logistics efficiency, facilitating coverage of Public Health Authorities' vaccination campaigns in countries with issues.

Coli MacDougall-Hunter

Hunter Global Tracking Ltd. 14, Avenue Industrielle 1227 Carouge Switzerland

The overcome of public health research data management chaos: exploratory study on research infrastructure implementation

Mélanie R. Maia^{1,2}, Marília Pauloc, Mariana Peyroteoc, Luís V. Lapão^{1,2,3}

¹UNIDEMI, Department of Mechanical and Industrial Engineering, NOVA School of Science and Technology, Universidade NOVA de Lisboa, Caparica, Portugal, ²Laboratório Associado de Sistemas Inteligentes, LASI, Guimarães, Portugal, ³Comprehensive Health Research Center, NOVA Medical School, NOVA University of Lisbon, Lisboa, Portugal

Background and objective: Digital healthcare research infrastructures integrate data, global health, people, processes, and technology. Public health decision-makers face problems of access to data and the current debate focuses on ethical and data protection issues, looking for systems' interoperability constraints. The aim of this study is to understand the process of digital healthcare research infrastructures.

Methods: The study is a literature review on digital healthcare infrastructures integrating data supplemented with two use cases of public health research implementation focusing on data management and protection processes at different scales (centralized-national and distributed-federated).

Results: The use cases presented are different in scales and nature, having multiple levels of constraints in the research infrastructure pipeline.

1. National, Portugal: literature identifies the bottleneck at the implementation and interoperability levels, for research systems. Review on national data protection emphasizes official deliberations, since the European general data protection regulation (GDPR) launch, focusing on health databases protection, the need of improving communication among institutions and professionals, and less bureaucratic processes for local implementation of health information systems.

2. Europe (EU) member states: review on EU official decisions on the adequate protection of personal data in the context of international research data flows, points to the need of FAIR processes and share of data. The bottleneck seems to be at national health security level, where policy dialogue is of major importance and national affairs need to be protected. Sharing data can vulnerable, therefore is controlled, sometimes not reflecting the process.

Conclusion: Jurisprudence, official and unofficial institutional documents, and peer review research publications give an important documental subtract for this research. First-hand experience will contribute to the reveal and validation of main constraints and possible solutions for the research problem. A roadmap for health research data protection implementation, in Portugal following the EU context is being set-up.

Tooth detection and numbering in panoramic radiographs using an artificial intelligence approach

Aneesa Ayoob¹, Venkatesh Vaddadi², Phaneendra Yalavarthy², Chandrashekar Janakiram¹

¹Amrita School of Dentistry, Kochi Amrita Vishwa Vidyapeetham, Kochi Amrita School of Dentistry, Amrita Institute of Medical Science Campus, Ponekkara P.O-682041 India, ²Indian Institute of Science, Bangalore

Introduction: Panoramic radiography is an imaging method for displaying maxillary and mandibular teeth together with their supporting structures. Artificial intelligence (AI) system was used to detect and number teeth on panoramic radiographs.

Methods: A data set of 600 randomly chosen panoramic radiographs of adults was used to train the system. The teeth numbering module classifies detected teeth images according to the FDI notation. It utilizes the classical VGG-16 CNN for the spatial arrangement of teeth.

Results: The total numbers of true positive, false positive, and false negative results were recorded and consequently, the estimated sensitivity, precision, and F-measure were 0.9559, 0.9652, and 0.9606, respectively.

Conclusions: The deep convolutional neural network system was successful in detecting and numbering teeth. Clinicians can use AI systems to detect and number teeth on panoramic radiographs, cephalometric landmark detection, teeth structures segmentation and teeth classification for dental recording.

Fighting denutrition in nursing homes

Tiba delespierre¹, Priscilla Clot-Faybesse²

¹Korian & Paris-Saclay 21-25 rue Balzac 75008 Paris France, ²KORIAN 21-25 rue Balzac 75008 Paris France

Background and objective: Korian® group, specialized in care and support for fragile people, manages 280 French nursing homes (NH). Its datawarehouse clinical narratives (CN), daily-fed by caregivers in the transmissions' table, contain key textual data about residents' care and health. Denutrition and malnutrition are highly prevalent among elderly inside and outside NH and impact health and autonomy among this fragile population. By building a denutrition cohort, computing successive body-mass indexes (BMI), following all the residents' health events, including falls, hospitalizations and deaths, adding pathologies, risk factors and CN, we can predict residents' denutrition.

Methods: First, we selected all residents with at least one transmission, from August 29, 2022 to October 02, 2022 from all 280 NH. We will follow them for twenty weeks, starting August 29. We extracted residents' age, sex, autonomy level, comorbidities, risks, hospitalizations, deaths, exits events as well as their BMI over time. Second, we labelled four BMI classes according to HAS (High Health Authority) thresholds: emaciated = below 20, undernourished = [20 - 22], well fed = [22 - 30], heavy = above 30. We added also 30 main pathologies classes according to four medical experts using the Delphi method. Third, by assessing correlations between our features and then, using tree classifiers we will be able to predict denutrition. Finally, combining clustering and survival analysis will help us grasp the whole denutrition process.

Results: We built a 21,856 residents cohort with 15,886 (73.4%) women and 5,771 men of mean age 87.6 +/- 8.2. We found 5,418 (25%) emaciated, 4.9 times more women of mean age 90, men being five years younger. Both sexes of this group showed a 0.4 autonomy level loss.

Conclusion: The 'emaciated', being slightly older, are particularly at risk. Adding CN labelled health information will deepen our residents' profile understanding and improve survival.

Paths to a public oral health for indigenous peoples: the use of the performance indicators evaluation matrix

Tainá Mafrá¹, Lucas Santos², Herika Mauricio³, Rafael Moreira³

¹Fiocruz Pernambuco MSc Student Brazil, ²Fiocruz Pernambuco PhD Student Brazil, ³Fiocruz Pernambuco Brazil

Background/objective

The management of indigenous oral health makes use of the indigenous health care information system (sias) in portuguese, among other functions, to monitor the impact of the actions performed by monitoring health indicators. In the context of oral health, although there are performance indicators dedicated to dental practice, these are not specifically dedicated to the context of indigenous oral health. Thus, especially since the coordination of the special secretariat for indigenous health (sesai in portuguese) in 2010, several operational challenges have arisen, among them, the effectiveness of the sias, with oral health data and indicators that can support the decision-making process of indigenous health planning, allowing the action impact, epidemiological situation and access to oral health services follow-up.

Methods: This study presents the construction of an evaluative instrument capable of generating parameters for the production of performance indicators appropriate to the context of indigenous oral health in Brazil. The application of the indigenous oral health performance indicators evaluation matrix (ioh-piem) aims to assess the suitability of performance indicators used in the sias to the context of indigenous oral health in Brazil.

Results: The instrument is elaborated by the researchers and validated by a field

expert workgroup. The ioh-piem is applied in questionnaire format using the delphi method, which seeks consensus from the participants, in successive rounds, and interspersed with controlled feedback. The participants are indigenous oral health managers, dentists and indigenous healthcare users, selected from the 34 special indigenous health districts (dsei in portuguese).

Conclusion: The answers are compiled and the results identify the criteria and indicators defined by the participants as appropriate to the context of indigenous oral health.

Implementing a Pregnant Women And Birth Registry in Karachi, Pakistan to provide digital identity to newborns and administer birth dose vaccinations

Vijay Dharma¹, Mubarak Shah², Nida Aslam¹, Danya Siddiqi³, Subhash Chandir⁴

¹IRD Pakistan Pakistan, ²IRD Global Canada, ³IRD Global United Kingdom, ⁴IRD Global United States

Background and objective: Despite concerted efforts to achieve universal and equitable immunization coverage, many children are still missed since they have no formal record of existence, making it difficult to track these 'invisible' children. We developed an electronic pregnant women and birth registry (pwbr) module that enrolls pregnant women and newborns visiting birthing facilities into a centralized database connected to the provincial electronic immunization registry (zindagi mehfooz; zm eir) in sindh province, pakistan.

Methods: We implemented the pwbr module at 15 birthing facilities in 8 'super high-risk union councils' (shrucs) in karachi, based on the prevalence and circulation of poliovirus and low routine immunization coverage. Pregnant women and their newborns were enrolled into the pwbr at the birthing facility through assigning them a unique qr-code based identifier that linked them to the provincial eir. We evaluated the impact of the pwbr on birth dose immunization coverage and timeliness among enrolled newborns.

Results: Between november 10, 2020, and december 31, 2021, we enrolled 33,335 pregnant women and 99.5% (17,942/18,021) of the children born at the birthing facilities. 88% (15,712/17,945) of the newborns were administered the birth dose of the polio vaccine at the facility, of which 99% (15,666/15,712) were vaccinated within 24-hours of birth. We observed that coverage rate for birth dose polio vaccine (93%) was higher among children enrolled in the eir through pwbr compared to those enrolled through other modalities (immunization centers, outreach, etc.) (43%). Timeliness of subsequent vaccines was also higher for children enrolled through pwbr compared to those enrolled through other modalities.

Conclusion: A birth registry module integrated in existing lmic health systems can effectively provide newborns with a digital identity and link them to the health system for effectively tracking their immunization status till completion.

DOI: 10.18332/popmed/164449

Designing and developing a telehealth services implementation model for tribal areas in nashik district, maharashtra

Vibha Bhirud¹, Dhanashree Apsinghekar¹, Shilpa Bhatte¹, Priyanka Vichare¹, Yogesh Lahinge¹

¹Intelehealth India

Introduction: Telemedicine canvas was developed to be used as a template to design and develop telehealth interventions in a given geographical or cultural context. Villages in the tribal area of nashik district, maharashtra in India, have little to no access to primary health care services. The areas are poorly connected to the main city of nashik and at times completely cut off during the monsoon season. Telemedicine will enable the villages to access good quality primary healthcare without the need to travel long distances.

Aim: To design and develop telehealth services for tribal communities materials and methods: a community needs assessment was conducted to identify the scope of work, context, challenges, and opportunities through in-depth interviews with community members, health workers, and local health providers. The implementation team, doctors, and internal evaluation team conducted a workshop to map priorities, opinions, and perceptions using the telemedicine canvas. The workshop was followed by a baseline survey to gather data for socio-demographic, gestational, wash, health access, and expenditure data from the community.

Findings: The community needs assessment helped focus the discussions during the workshop and helped define the goals and scope of work of the program. Discussions guided by the telemedicine canvas helped develop a theory of change, requirements for the software application, and baseline survey. The

implementation model designed for the tribal areas was to implement the digital solution with health workers as intermediaries in-field. The model consists of both telehealth (education and awareness) as well as telemedicine (consultation by qualified doctors).

Conclusion: The canvas provides a framework to map out internal and external challenges of the ecosystem, opportunities, and perceived end-user needs. It provides a useful framework to develop user needs for the technology solution, identify and plan for potential barriers to implementation, and training modules for health workers.

Creating a clinical decision-making algorithm in order to build a one health knowledge repository to help support and improve the public health surveillance system

Plácida Maholela¹, Osvaldo Frederico², Inocência Chongo¹, Júlio Rafael³

¹Instituto Nacional de Saúde (Mozambican National Health Institute) Mozambique, ²Inlamea Instituto Nacional de Saúde (Mozambican National Health Institute), ³Instituto Nacional de Saúde (Mozambican National Health Institute) Mozambique Mpoki Mwabukusi Sokoine University

Recording and reporting diseases within the community is still a high burden and in a country such as Mozambique, with low capacity for risk management of emerging and re-emerging diseases specially in remote areas, early detection or capture has been considered crucial. Using mobile devices to capture disease cases have enhanced timely reporting and prompt response of disease events, particularly those cases that do not report to the health facilities, preventing the health surveillance system from being able to assemble and include the information in their database for future decision-making purposes. Nevertheless, these same captured events can be used as a tool to promote early detection of cases, through the prediction of likely disease conditions based on the signs and symptoms reported, thus contributing for the reduction of disease spread and the occurrence of pandemics and at the same time promoting and enhancing local capacity for case management.

Health technicians from health facilities will be traced and asked to participate in a questionnaire-based interview, where data on their experience with clinical manifestations of emerging and re-emerging disease, as well as endemic disease cases will be compiled. This data will then be compared to a preset clinical manifestation scores map, which will then be weighed and associated with a particular disease through a logistic regression model which is able to obtain the probability of occurrence of a particular event, as well as the influence of each independent variable on the event studied. By the end of this study, a combined set of clinical manifestations will be used to capture and determine the probability of the occurrence of a correspondent set of diseases in a determined place, in order to enhance the local capacity to address health related issues, whilst also timely reporting to the national and subnational level.

Assessment of quality attributes impacting end-users' experience with mobile health applications in Saudi Arabia: A systematic review

Mohammed Senitan¹, Abdullah Alotaibi¹

¹Saudi Electronic University Riyadh Saudi Arabia

While a number of mobile health apps are available for managing prescriptions, managing chronic care, managing women's health, managing personal health data, managing healthcare and fitness, and managing nutrition and diet. The usability of the apps is what determines their success. The purpose of this systematic research was to evaluate the quality factors influencing end-user satisfaction with mobile health applications in Saudi Arabia. For this systematic review, which included the most recent literature (2017–2022) on end-user experiences with mobile health applications in Saudi Arabia, we searched Pubmed, Medline, CINAHL, EmBase, Google Scholar, Springer Link, Saudi digital library (SDL), Association of computing machinery (ACM) digital library, and IEEE Xplore databases. The identified papers calibre and consistency were checked using PRISMA criteria and critical appraisal methods. 5008 duplicate articles were removed from all databases that had been searched after the original search. Furthermore, after looking at their titles and abstracts, 1941 papers were taken out of the study. Based on the aforementioned standards, the main author and co-author reviewed and chose the remaining 102 articles. There were 21 publications total in this study that were deemed to be acceptable. All of the chosen studies interviewed 15727 people in total. The most popular mobile health apps among the chosen studies were reported to be Tawakkalna, Tabaud, Seha, Mawid, Tataman, Ana Alsukary, and Sehhaty. In the

selected studies for this systematic review, satisfaction (n=9) was the feature that was most frequently employed, followed by usefulness (n=4), awareness (n=4), acceptability (n=2), learnability (n=2), efficiency (n=2), flexibility (n=1), and errors/technical concerns (n=1). Unexpectedly, privacy and security-other crucial usability factors for mobile health apps were not on the list of the most often mentioned factors. The meta-analysis of three chosen research revealed that younger age groups and men were more satisfied with using mobile health apps.

Infectious disease tracker-mysejahtera mobile apps

Husni Hadi¹

¹Ministry Of Health Malaysia malaysia

Background and objective: Infectious disease tracker is a feature in MySejahtera mobile health apps that provides real time number of active infectious disease cases location namely dengue fever, human and animal rabies, measles, hand-foot-mouth disease (HFMD), and tuberculosis. The locations of reported cases are mapped to display the numbers of active cases around any selected search point. Hence, public will be able to see the number of active cases for each disease reported from their point of search.

Methods: Verified reports of each diseases were analyze and geocoded by Malaysian health authority. Mapping of the geocoded data from each infectious diseases are used to enable the tracker function. The number of infectious disease cases shown does not include the name, address, latitude, or longitude or any means of disclosing the patients' exact coordinates. The duration of active cases are varies from one disease to another while the distance depends on the type of infectious disease. It ranges from a radius of 200 metres for dengue cases and up to a radius of 5 km for hand-foot-and-mouth disease.

Conclusion: This feature is mainly to create awareness among the public regarding the risk of infectious diseases that may exist around their area. High-risk individuals (children, elderly, immunocompromised) can avoid from going into areas with high number of active cases. The community can arrange for cleaning campaign and conveying the information via social circle (e.g. WhatsApp group, Telegram channel, Facebook) especially during gatherings. This approach advocates the shift from a disease-oriented model to a person-centred wellness approach. The health authority and society work together in more effective ways of communicating about the virus, and how public able to keep themselves safe. This initiative indirectly empowering the public with health information towards putting a stop to an outbreak and improves population health.

Human factor on data safety: Resident doctors attitude towards cybersecurity on the workplace

Gerardo Altamura¹, Valeria Puleo¹, Mario Nurchis¹, Gianfranco Damiani¹, Fidelia Cascini¹

¹Università Cattolica del Sacro Cuore Italy

New health technologies bring hope for a better and more efficient process of care. However, the use of new instruments entails new doubts on efficacy and safety. Verizons 2018 Data Breach Investigation Report found out that the healthcare sector was the most affected one by personal data breaches, accounting for 24% of all found breaches. Researchers at Stanford University calculated that about 88% of all data breaches are caused by human error. This study aimed to investigate this topic by collecting results of a survey on cyber security in the workplace among resident doctors of the IRCCS Policlinico Gemelli. Based on previously published and verified works, this survey followed a cross-sectional study approach. Sixty-three correct statements related to knowledge, behavior, and attitudes of resident doctors were submitted. Doctors were invited to answer whether they didn't know, agreed, or disagreed with the stated sentence. Zohosurvey®, an online service, was used to deliver the file link, and to take attendance and collect data. Fifty resident doctors answered to the invitation. All responders gave feedbacks to all 63 questions. The behavior section saw the highest number of shared "agree" answers, especially regarding the need not to post content related to work on social media(88.46%) and to use different passwords for different accounts(88.46%). Similarly, the attitude section registered a high number of "agree" answers, especially regarding social networks, in particular referring to avoiding to post sensitive material(88.46%) and the importance not to use the same password for social networks and work mails(88.46%). A high number of "disagree" answers related to the knowledge section. This survey highlighted how, although good behaviors and attitudes towards cyber security already exist among responders, there is the need to focus on knowledge, with lessons and educative material to fill the gap which brought

to such unsuitable answers among responders.

Telehealth as a tool to optimize the pre-hospital pathway: An extreme case study in southern Italy

Anna Gagliardi¹, Francesca Troiano², Carmela Puleo³, Giuseppe Furia⁴, Patrizia Chierchini⁵, Maddalena Quintili⁶

¹University of Foggia Department of Economics Via Romolo Caggese, 1, 71121 Foggia FG Italy, ²Local Health Authority Roma 1, ³Local Health Authority Roma 1 Risk Management Area Borgo Santo Spirito, 300193 Roma RM Italy, ⁴Local Health Authority Roma 1 Hospital Management Area Borgo Santo Spirito, 300193 Roma RM Italy, ⁵Local Health Authority Roma 1, ⁶Local Health Authority Roma 1 Risk Management Area Borgo Santo Spirito, 300193 Roma RM Italy

Background and Objective: The COVID-19 pandemic has had a significant impact on health systems around the world. In particular, the suspension of scheduled surgical activities, guaranteeing only urgent surgeries, has inevitably lengthened the waiting time for treatment of patients with a diagnosis other than COVID-19, resulting in inefficient management of the operating rooms. This study aims to describe the advantages of telehealth services for managing patient operations and care. **METHODS** This study, focusing on a dataset including 166 major surgery interventions from the data warehouse of the "Casa Sollievo della Sofferenza Research Hospital" (Italy) from January 2021 to November 2022, examined, in particular, the Pre-hospital Pathway. The research, analyzing the leading Key Performance Indicators and comparing them between the two years of investigation (2021 in the absence and 2022 in the presence of the telehealth service), highlighted potential changes in organizational and operational dynamics. **RESULTS** The main results indicate a better efficiency of the Time Management of the operating room. The data show a significant reduction "of the index of re-planning of surgical operations" from 16.27% in 2021 to 7.5% in 2022. In addition, the number of surgeries performed in the operating room has been optimized from 71.4% in 2021 to 90% in 2022. **CONCLUSION** Introducing the telehealth service in the Pre-hospital Pathway is a valuable tool to spread the culture of Change Management within the health organization. Enhanced operations management and improved patient experience are the tangible results of this study.

The use of social media-communities by diabetes patients - a scoping review

Hocke-Bolte Zora¹

¹University of Education Schwäbisch Gmünd Germany

Background and objective: There are over 420 million people with diabetes worldwide. The World Health Organization (WHO) estimates that the number of diabetes-related deaths will double by 2030. Living with diabetes requires the ability to seek and apply health information. The aim of the scoping review is to find out what evidence is available for social media usage by diabetes patients and whether it is being used to search for health information or to obtain emotional support.

Methods: A scoping review was conducted to report relevant literature published prior to 2022. Attention was paid to the emphasis of digital health literacy, emotional support and variations within the different studies.

Results: There are a lot of new methodological approaches, which are published frequently as pioneering work. Emotional support often plays a more important role in the use of social media than seeking health information, but in-depth understanding and explanatory patterns are lacking.

Conclusion: Future studies should investigate what explanatory patterns can be used to understand social media use by diabetes patients. Those would allow improved targeted health promotion and prevention measures.

Telemedicine and chronic patient: perceived effectiveness of asthmatic children's caregivers

Elisabetta Ceretti¹, Caterina Antonelli², Cristina Quecchia³, Valeria Gretter³, Raffaele Badolato⁴

¹University of Brescia Department of Medical and Surgical Specialties, Radiological Sciences and Public Health, University of Brescia Italy,

²University of Padova Master Degree Course in Health Assistance, University of Padova Italy, ³ASST Spedali Civili, Brescia Paediatric Allergology Clinic, Child Hospital, ASST Spedali Civili, Brescia, Italy, ⁴University of Brescia

Department of Clinical and Experimental Sciences, University of Brescia Italy

Introduction: The outbreak of the Coronavirus pandemic and the restrictions imposed to limit Sars-CoV-2 circulation have prompted the use of telemedicine as an alternative method of assistance, especially for chronic patients. The aim of the study was to evaluate the perceived effectiveness of introducing telemedicine into the diagnostic therapeutic-educational pathway (DTEP) of asthmatic children treated at the "Io e l'Asma" Centre of the Children Hospital, ASST Spedali Civili in Brescia, Italy.

Methods: From July to September 2022, a questionnaire was administered to a sample of caregivers of asthmatic children who made at least one telemedicine visit in the period between March 2020 and September 2022. The 28-questions questionnaire was divided into three macro-areas concerning subject personal data, number and type of visits and perception about the visits, respectively.

Results: We collected 108 questionnaires. Most of the subjects were parents, female and Italian, and participated in more than one telemedicine visits: 58% of the subjects were satisfied of the organization of the telemedicine visits, stating they were willing to continue them even after the pandemic had ended. Furthermore, 75% of subjects experienced empathy with the doctor despite the distance, in contrast with the belief about telemedicine which claims that the absence of direct contact between doctor and patient negatively affects the conduction of the visit.

Conclusions: Telemedicine at the Io e l'Asma Centre was introduced for necessity in 2020, during the pandemic; but, its sudden introduction did not allow the planning of a gradual integration strategy between traditional and telemedicine visits, and better preparation and training of patients and practitioners. However, the results of the study showed that the caregivers of asthmatic children appreciated use of telemedicine for assistance of asthma which could integrate the traditional approach for treating the disease.

Methodological approaches based on machine learning in the use of big data in public health: a systematic review

Giuseppe Migliara¹, Antonio Sciurti¹, Maria De Biasi¹, Valentina De Nicolò¹, Daniela Mercuri¹, Valentina Baccolini¹, Carolina Marzuillo¹, Paolo Villari¹, Corrado Vito¹

¹Sapienza University of Rome Department of Public Health and Infectious Diseases Piazzale Aldo Moro 5, 00168, Rome Italy

Background and objective: Since the past few years, there has been a growing interest for the use of massive amounts of data - i.e., the Big Data - in medical research, for their potential role in changing the approach to personal care, medical care and public health. However, part of the difficulties in introducing Big Data in Public Health is constituted by the problem of abandoning the classical statistical methodology in favour of the methodologies mainly based on machine learning (ML). We performed a systematic review to investigate the ML methodologies used in studies of interest for public health, with particular attention to their development and validation.

Methods: The research was performed in PubMed, Scopus, and Web of Science databases. Studies investigating risk prediction reporting use of ML methodologies in public health fields of interest were included. The following data were extracted: study design, target population, data source, type of machine learning algorithm used, study objective, methodological approaches used in the development of the ML algorithms.

Results: The search retrieved 26340 records. 26 studies were included. 15 studies used Random Forest models, while the use of other types of models was more sporadic. The risk of overfitting of the models developed in the 24 studies that used supervised algorithms, based on tuning methods, internal validation methods and external validation methods, was found to be high in 6 studies, low in 15 studies and minimal in 3 studies.

Conclusions: Almost a third of the studies used approaches inadequate for the tuning, training, and validation of machine learning algorithms. Only three studies applied appropriate external validation techniques. These methodologies will have to be carefully guided, both in the standardization of their development, and in the assessment of their effectiveness, to ensure that their potential can bring real benefits to the entire population.

Exploring data visualizations as a tool to make ai more accessible for qualitative researchers in the healthcare field

Luka Mazza¹, Luka Mazza¹, Jim Wallace¹, Plinio Morita¹

¹University of Waterloo Canada

Background and objective: Qualitative data analysis allows healthcare researchers to understand lived-in experiences of patients and practitioners. However, it requires time and effort, which is not always available. A potential way to assist is to use artificial intelligence as a tool to help researchers with data exploration. However, many qualitative researchers do not have programming skills to use AI and are reluctant to lose their sense of agency and serendipity when conducting research. As a potential way to bridge this gap, we explored the use of data visualizations to foster researcher agency and make AI more accessible.

Methods: We used Design Science Research to develop a series of prototypes. First qualitative semi-structured interviews were conducted with 5 qualitative researchers to gauge how they interacted with their data and what they expected of data visualization for working with AI. The interviews were guided by the concept of agency and how it can be fostered through media interaction. Then, the results were compiled into guidelines for the development of 4 datavis prototypes, each focusing on fostering agency through a different channel.

Results: Researchers reported needing freedom to move within a visualization the most. High levels of tactile interactivity increased the trust in the AI and made participants feel like they were working as a partnership. Additionally, freedom to co-create the visualization instead of being presented with a finished product was cited as satisfying. Both elements made participants feel ownerships over their own research and a sense of camaraderie with the AI.

Conclusion: For qualitative researchers, agency in data analysis is heavily correlated with freedom of choice and movement. Those elements directly impact their sense of ownership of data and trust in AI. Overall, data visualizations seem to show promise in making AI more accessible for people with no programming experience.

DOI: 10.18332/popmed/164352

Impact of digital health interventions for adolescents with type 1 diabetes mellitus on health literacy: a systematic review

Aurélia Naef¹

¹MHH, Germany

This systematic review provides an overview on the impact of digital health interventions for adolescents with type 1 diabetes on health literacy and derive recommendations for further research.

Background: Evidence shows that living with diabetes mellitus type 1 (T1DM) in adolescent age is particularly challenging and difficult to manage. A high level of health literacy is important to prevent and avoid debilitating complications. Despite the increasing prevalence and incidence of T1DM and the large use of digital health interventions, little is known about the association between this use and health literacy.

Methods: Electronic searches were performed in five databases: PubMed, The Cochrane Library, EMBASE (via Ovid), Web of Science and PsycINFO from 2011 to 2021. In addition, grey literature searches were conducted. Relevant studies that have been missed by electronic and hand-searching strategies were searched in the reference lists of all included studies. The review followed PRISMA guidelines. Two researchers screened abstracts for initial eligibility and applied the inclusion and exclusion criteria to the relevant full-text articles. Quality was assessed.

Results: Out of 981 studies, 22 were included in the final review. Most primary studies included in this review were judged as moderate overall risk of bias or with some concerns and most of the secondary studies as critically low quality reviews. Our Findings suggest that the interplay of health care providers (HCP) and patients through social media helps the management of the disease. This corroborates Bröder et al.' (2017) dimension of 'communication and interactions' in their concept of health literacy.

Conclusions: For adolescents with T1DM, social media may be a specific and beneficial intervention for an improved communication and interaction with their HCP. Further research should investigate what specific form of social media suits best for which adolescents.

Popul. Med. 2023;5(Supplement):A626

A pilot randomized trial for smoking cessation app in Arabic language: a study protocol

Ola Soudah¹, Alameen Alsabbah¹, Mo'men Dalalal'ah¹, Carmen Svanes²

¹Faculty of Medicine, Yarmouk University, Jordan, ²Faculty of Medicine, The University of Bergen, Norway

Tobacco consumption in the middle-east region is very high. Many smoking cessation apps show to be effective in reducing smoking rates. To date, smoking cessation apps in Arabic mostly are translated from English. No study tested the

apps efficacy of the Arabic version in our region. Moreover, the cultural context is not addressed. The purpose of this study is to develop a smoking cessation app in Arabic (iEndSmokin, **إند سموكين**) and to examine its efficacy. The app will be based on clinically proven behavioral therapy as Cognitive-Behavioral Therapy (CBT) and Acceptance Commitment Therapy (ACT). In this pilot randomized clinical trial, smokers will be randomized and allocated in a 1:1 ratio to app intervention or to the control group. Participants in the control arm will attend educational and motivational sessions. The intervention will last for 6 months and participants will be followed for 12 months. The primary outcome is a 30-point prevalence of smoking abstinence and normal saliva cotinine level at the end of the study. A 50% reduction in the smoking rate will be the secondary outcome. Long-term abstinence will be measured after 12 months. The sample size will be around 200 smokers who are willing to quit. Recruitment will be between April 2023 to May 2023 or until the process is completed. The study will start from June 2023 to December 2023 with 4 follow-up points: 1) baseline, 2) 3 months, 3) 6 months, and 4) 12 months. Data will be analyzed based on intention-to-treat. Our main hypothesis, the iEndSmokin app will be an effective, accessible, and feasible smoking cessation app targeting all Arabic speaking countries. All ethical approval will be obtained from Yarmouk University Institutional Review Board (IRB) prior to app development and recruitment. The study Results will be disseminated via peer-reviewed publication.

DOI: 10.18332/popmed/164835

Study on effectiveness of online learning among medical students of Bpkis during COVID-19

Laxmi Subedi¹

¹School of Public Health and Community Medicine, Koirala Institute of Health Sciences, Nepal

Background and objectives: Responses to the COVID-19 pandemic in medical education have varied from country to country, from closures of medical schools to online learning approaches to abiding by country-specific measures such as social distancing. The sudden transition from on-campus learning to exclusively online learning is challenging for both faculty and students and has required a lot of preparation in a short time. This study focuses on assessing the effectiveness of online teaching among medical students of BPKIHS during COVID-19.

Methods: A cross sectional study was done among the 100 undergraduate medical students of BPKIHS. Convenient sampling method was used to select study participant. Almost equal number of students from each batch were selected randomly. Mixed method was used for the study. Stratified random selection was done in equal proportion of 1:1. Self-Administered, Semi-structured questionnaire among the Medical students was administered using Google form and open-ended questionnaire was used for qualitative study.

Results: In our online survey 62.0% of the students agreed that the sessions were up to their expectation, 48.0% reported that session/course were well structured, for 55.0% the relevant questions asked motivated learning during online sessions. The pace of the sessions was very fast for 62.0% of the students, 35.0% of the students wanted more visual aids, 41.0% of respondents said voice quality was not good during the session, 59.0% of the students reported online classes were interactive whereas 83.0% of students missed direct, in-person interaction. Adequate Visual aids, good communication and time management skills, good internet strength and quizzing during the sessions were suggestions for improvement of online teaching.

Conclusions: According to our Findings most of the students found online sessions effective however improvement in technical issues (audio visual aid, internet connection etc.) would make the online session more effective.

Please mind the gap between guidelines & behavior change: a systematic review and a consideration on effectiveness in healthcare

Nicola Bellé¹, Stefano Gandolfi²

¹Laboratorio MeS, Management e Sanità, Sant'Anna School of Advanced Studies, Pisa, Italy, ²Sant'Anna School of Advanced Studies, Pisa, Italy

Background and Objectives: This study is a systematic review, following the PRISMA Methodology, to explore and take stock of extant scholarship on the relationship between practice guidelines and behavior change in the context of healthcare provision.

Methods: Scopus and Web of Science were researched according to our PICO(T) Keywords. The initial search yielded 624 Results, which were then reevaluated based on inclusion criteria to remove duplicates, items besides research articles,

and items outside the scope of the review. A total of 67 articles were analyzed in depth.

Results: The 67 studies in our final sample come from 25 countries, with the UK, Australia, Canada, and the US being the most represented. In terms of populations of interest, about 45% of the studies in our sample specifically focus on medical doctors, and some 37% generically target healthcare workers. Prescription is the most frequently investigated behavior, followed by hand hygiene. Guidelines significantly influence behavior in the intended direction in less than half of the studies; Results are mixed in more than one-fifth of the cases and significant but contrary to expectations in 18% of reviewed articles. In terms of research design, most studies are based on quantitative methodologies, followed by qualitative work, literature reviews, and theoretical contributions. Conclusions: The study speaks to academics and healthcare professionals alike, aiming to improve the effectiveness of guidelines as a tool for positively changing behavior in the healthcare context. It provides an exhaustive mapping of the relationship between guidelines and behavioral changes in health professionals, including the factors that mediate or moderate this relationship and the methodologies adopted in this research area.

DOI: 10.18332/popmed/165014

Implementation and evaluation of an interprofessional Tele-Care approach in home care in Germany

Andrea Chmitorz¹, Theresa Zürn², Hannah Haumann³, Stefanie Joos³, Isabel Kächele⁴, Peter König⁴, Cornelia Mahler³

¹Institute for Collective Health, Esslingen University of Applied Sciences, Germany, ²Esslingen University of Applied Sciences, Germany, ³University Hospital Tübingen, Germany, ⁴Furtwangen University of Applied Sciences, Germany

Tele-Care is increasingly considered as a cost and time-effective approach to deliver health services in remote or rural areas. Although remote medical consultations have become more common in Germany in recent years, interprofessional approaches including nursing and medical professions as well as patients and caregiving relatives have not been implemented to date. Our aim is to implement and evaluate an interprofessional online home care visit including nursing service and general practitioner, patient and caregiving relative in-home care to increase and ensure patient safety and the quality of care. The project will be conducted in the SouthWestern part of Germany. The development and subsequent implementation of the online interprofessional visit will be carried out together with ambulatory nursing service and general practitioners. Current status and anticipated requirement of the partners will be analyzed, visions developed, structures for interprofessional cooperation defined and technical infrastructure created. Data from home care nurses, general practitioners, patients and their relatives will be analyzed during the entire process. Qualitative data will be collected to assess potential obstacles in the implementation process; quantitative data to evaluate medical and nursing-related outcomes, patient-related outcomes and caregiver burden using standardized and validated questionnaires. The results will shed light on interprofessional aspects relevant for successful implementation of online-based visits and interprofessional collaboration in the German primary health care system. The project is funded by the Ministry of Social Affairs, Health and Integration of Baden-Wuerttemberg, Germany.

Preventing public health crises: an expert system using Big Data and AI in combating the spread of health misinformation

Jasleen Kaur¹, Irfhana Hussain¹, Matheus Lotto¹, Zahid Butt¹, Plinio Morita¹

¹University of Waterloo, Canada

Background and Objective: Health misinformation disseminated on social media has detrimentally affected the general population's attitudes toward public health measures, leading to costly and harmful public health crises around the world. Currently, public health officials cannot mitigate these health misinformation trends due to a lack of a comprehensive expert system capable of collecting and analyzing large amounts of social media data. The objective of this study is to design and develop a big data pipeline and ecosystem for the identification and analysis of health misinformation on social media named the Misinformation Analysis System (MAS).

Methods: Python, the Twitter V2 API, and the Elastic Stack are the main technologies used in developing the MAS system. The MAS system extracts social media data from the Twitter V2 API using its Data Extraction Framework and applies automatic health misinformation analysis using a pre-trained Latent Dirichlet Allocation (LDA) Topic Model, Sentiment Analyzer, and Information Disorder Identification

machine learning model. The analyzed data is then visualized through dashboards and analytics after being loaded into the Elastic Cloud deployment.

Results: The system is performing efficiently and accurately. Independent investigators have successfully utilized the system to extract significant insights for a fluoride-related health misinformation use case, spanning a period of 6 years, from 2015 to 2021. The system is currently being used for a vaccine hesitancy use case, spanning a period of 15 years, from 2007 to 2022, and a heat-related illnesses use case (2011 to 2022), respectively.

Conclusions: The novel MAS expert system has the potential to help public health officials globally to detect and analyze misleading health information. Moreover, this system can grow to integrate social media data from multiple sources into dashboards for a multiplatform analysis and to support social media data written in non-Western languages.

Use of telehealth resources in primary care and its association with facing the COVID-19 pandemic in Minas Gerais, Brazil

Alaneir Santos¹, Liliana Dramos¹, Delba Santos², Raphael Aguiar¹, Solange Godoy³, Maria Senna⁴, Mariana Freitas¹, Elis Borde¹, Rosângela Perillo⁵, Rogêli Peixoto⁴, Rafaela Pinto⁴, Antônio Matta-Machado¹, Veneza Oliveira¹

¹Faculty of Medicine, Universidade Federal de Minas Gerais, Brazil,

²Universidade Federal dos Vales do Jequitinhonha e Mucuri, Brazil, ³Nursing

School, Universidade Federal de Minas Gerais, Brazil, ⁴Faculty of Dentistry,

Universidade Federal de Minas Gerais, Brazil, ⁵Universidade Federal de

Minas Gerais - Faculty of Medicine, Brazil

Background and Objective: Use of telehealth resources increased dramatically during the COVID-19 pandemic. This study set out to examine associations between the level of incorporation of telehealth resources and the level of Primary Health Care structuring to deal with the COVID-19 pandemic in the State of Minas Gerais, Brazil. Methods: A cross-sectional study carried out at the end of 2020, with a sample of 260 Primary Health Care working in the State of Minas Gerais, Brazil. Two variables were created - Level of the Primary Health Care structuring to deal with the COVID-19 pandemic and Level of telehealth structuring, involving: Telehealth-based training targeting the community, Telehealth-based medication strategies, number of computers and electronic devices, consultations and monitoring of COVID-19 patients using Telehealth resources, Information and Communication Technologies - and Telehealth-based monitoring of chronic patients, internet availability and teleactivities. Associations between variables were examined using the Tukey's test for multiple comparisons and the Spearman correlation. Variables associated with socioeconomic dimensions and healthcare were also analyzed.

Results: Levels of telehealth structuring in Primary Health Care ranged from poor (43%) to regular (40%) in most cases. Most Primary Health Care teams had regular (56%) or good (37%) levels of Primary Health Care structuring to deal with the pandemic. Telehealth use and COVID-19 tackling ability were significantly correlated ($p < 0.050$). The higher the level of telehealth use, the better the ability to deal with COVID-19 (0.45 ; $p < 0.001$). No correlations with human development index, number of hospital beds and percentage of health insurance plans were detected. Primary Health Care was structured to tackle the pandemic. However, there is a lot to be done before telehealth resources are effectively incorporated into Primary Health Care. Conclusions: Whenever incorporated, telehealth resources contributed a more robust primary care structuring to deal the COVID-19 pandemic.

Mental health topics in social media during the COVID-19 pandemic - a literature review

Virve Pekurinen¹, Tia Koivu¹, Pirjo Lindfors², Katja Joronen¹

¹University of Turku, Finland, ²Tampere University, Finland

Background and Objective: The COVID-19 pandemic has increased psychological distress and the use of social media, especially in young people. The continual use of social media can undermine people's mental well-being. However, social media can provide peer support by enabling people to share their mental health experiences. Still, little is known about mental health communication on social media during the pandemic. The aim of this review is to describe the existing research related to mental health communication on social media during the COVID-19 pandemic.

Methods: The peer-reviewed literature was reviewed using the search terms, such as social media, mental health, and COVID-19. The databases used were APA PsycINFO, CINAHL, Pubmed, and Web of Science. A manual search was also

conducted. Studies were excluded if the study population consisted of the elderly or social-/healthcare professionals, or if the mental health conversations were related to specific health problems or specific peer-support groups and networks. The search resulted in 1970 references, of which 19 studies were selected.

Results: The studies (N=19) were conducted in North America (63%), in Asia (32%), and in Australia (5%). Machine learning was used in the majority of the studies. The studies examined communication on Twitter (58%), Reddit (26%), Sina Weibo (11%), and YouTube (5%). The communicated mental health topics included depression, suicidal thoughts, anxiety, fatigue, poor sleep quality, stress, and feelings of loneliness and fear. Peer support and advice were also communicated.

Conclusions: Mental health topics are communicated via social media, suggesting that social media platforms are a useful method to identify ongoing prevalent, and even potentially emerging, mental health topics. The existing research focuses mainly on Twitter; therefore, research is needed on other commonly used social media platforms among adolescents, such as YouTube. Research regarding users' experiences with peer support on social media is also needed.

Use of social media associated with health promotion: a new reality in Dentistry

Bárbara Fernandes¹, Caroline Santos², Cláudia Coscarelli³, Juliana Araujo³, Marcus Bezerra³, Olívia Gonçalves³

¹Serviço Social do Comércio - Rio de Janeiro (SESC-RJ), Brazil, ²Serviço Social do Comércio, Rio de Janeiro, Brazil, ³Serviço Social do Comércio (SESC-RJ), Rio de Janeiro, Brazil

Health education, whether face-to-face or using digital tools, acts as an interdisciplinary process of knowledge construction. The Serviço Social do Comércio - Rio de Janeiro (Social Service of Commerce - Rio de Janeiro) (Sesc-RJ) has health prevention as its premise, valuing educational activities throughout the clinical care of the patient. With the COVID-19 pandemic, social media stood out as a tool to maintain these activities. This study intends to carry out a research on the dissemination of health promotion information by Sesc RJ Dentistry, through the Instagram profiles @sescrj and @sescsantaluziarj in publications in the format of reels, and to evaluate the importance of this practice even after the return of face-to-face activities. A metric evaluation regarding the number of posts in the format of reels and their views was performed from May 2021 to October 2022; in addition to a survey regarding the monthly average of face-to-face attendances in health education promoted by dental clinic of Sesc Santa Luzia in 2019 and 2022. All these data were extracted from the Sesc statistical system, which are accounted for in the month following production, based on Public Domain information and available in aggregate form, without individual identification. Sesc RJ has an amount of 78 publications and a monthly average of 45623 views. And the number of publications regarding Sesc Santa Luzia is 68 and 5138, respectively. The monthly average of face-to-face dental appointment at Sesc Santa Luzia in 2019 was 2557 while from March to October 2022, the number of patients was 2583. According to the results obtained, it was ascertain that the alternative of expanding knowledge in health through the technological approach was successful and that it should be maintained even after the end of social isolation. Thus, social media reinforced health education in the dissemination of knowledge.

The "Octopus" project: a digital health model for supplying glaucoma care in Italy

Carmela Carnevale¹, Francesco Oddone¹, Angela Mastromatteo¹

¹IRCCS Fondazione G.B. Bietti Italy

Background: The current guidelines for glaucoma management suggest that patients perform a mean of three eye examinations per year associated with functional/structural exams. However, most of the primary territorial centers (ASL) are not equipped with the instruments for glaucoma diagnosis/follow-up. Therefore, these tests are carried out exclusively at the secondary specialized referral centers leading to a progressive overcrowding of the structure, increasing in waiting times and difficulties in ensuring an adequate continuity of care for glaucoma patients.

Methods: we analyzed the current territorial and hospital outpatient activity in order to find critical areas, specific problems and needs. The project will embrace two phases: definition of the network and digital platform and creation of a "point of care (POC)" physically located within the ASL and managed by the secondary referral center. The POC will be equipped with all the instruments required for the complete follow-up of the stable glaucoma patients.

Results: The digital platform provides a strong connection between the healthcare infrastructures both on the administrative, technical and clinical level allowing to share clinical patients' data including the exams' results. The actors involved will provide, through the platform, all the clinical patients' data necessary to send stable patients from the secondary referral center to the POC or to send cases that require para-surgical/surgical management or specialistic evaluation from the ASL to the secondary referral center. The visit or further diagnostic tests will be scheduled online, through a shared agenda, with a significant reduction of the waiting list allowing to schedule the periodic follow-up based on the individual risk level.

Conclusion: The integrated digital network could improve the patient management, the effectiveness and efficiency of the healthcare system ensuring the continuity of care for the management of chronic-degenerative disease.

⁶SESC - Social of Commerce in Rio de Janeiro

Introduction: Inserted in a broad concept of health, the promotion of oral health transcends the technical dimension of dental practice. Therefore, the need and efforts through Oral Health Education increase, with the purpose of enlightening the population about oral diseases and encouraging changes in general habits. During the COVID-19 pandemic, face-to-face activities were restricted, so digital media (YouTube, facebook and Instagram) emerged as an alternative for sharing content, aiming to promote health, prevent disease and continue the dissemination of knowledge, provide people with simple and low-cost alternatives for their well-being and better quality of life.

Aim: Quantitative evaluation of the use of digital media as a tool in the Oral Health Education strategy by the dental team of the Mobile Unit OdontoSesc, which belongs to the Social Service of Commerce in Rio de Janeiro.

Methodology: A quantitative exploratory study, based on an institutional database system (Planning and Execution System - SPE), which presents the number of views collected in posts on digital media, from January to December 2022. The posts were weekly or fortnightly, with content related to the main complaints and demands previously observed with face-to-face consultations. The contents were produced in short forms (videos and reels).

Results: The content shared on digital media had a reach of 71683 views/year, which represented an additional 66% in face-to-face educational activities.

Conclusion: The success presented by the new implementation strategy in the activity restriction period led the tool to be used, concomitantly, with face-to-face health education actions, aiming at a greater population reach and dissemination of knowledge, to foster autonomy and collaborate for a better quality of life for the population.

Dashboard as a public transparency tool for management and planning data in Brazilian healthcare system

Marília Coser Mansur¹, Cristina Hamester¹, Georgea Riff¹, Nathalia Derengowski¹, Wania Ferreira¹, Davlyn dos Anjos¹, Tania Barbosa¹, Ligia Braun¹

¹Ministry of Health - Brazil

Background and Objective: Brazil has a public unified healthcare system named sistema Unico de Saúde (SUS). Healthcare management, financing and delivery are responsibilities of the three levels of government, the union, states, and municipalities. For monitoring and control, managers must fill in data in several planning tools, such as the current manager planning system called Digisus Gestor Modulo Planejamento (DGMP), in order to guarantee transparency about the status of the health planning and management mandatory documents. Those documents might go under further evaluation by the health council, which is the collegiate that acts in the formulation of strategies and as a society control

of health policies implementation in the corresponding government level. The objective of our project is to present the newly developed dashboard as a tool offering public transparency and enabling comparative analyses of sus planning instruments status.

Methods: A team of ministry of health professionals developed the dashboard between July 2021 and June 2022, in weekly meetings under constant cooperation and collective effort, using microsoft power BI as supporting technology.

Results: Maps, graphs and tables illustrate the situation of sus planning and management instruments in the dashboard, providing a public, friendly interface that is easily available. This technological innovation makes it possible to display the status of sus planning instruments in government levels and health regions. Furthermore, the application of a spatial clipping frame provides the basis to elaborate technical reports and qualitative analyses of those instruments.

Dashboard available at website : <https://lisaude.com.br/paineldgmp/>

Conclusion: The dashboard innovates by providing transparency of Brazilian unified health system planning data, thus supporting government decision making and social control policies.

Philippines's Family Planning Health Information System: From the Implementers' Lens

Blanca Rellosa¹, Alethea De Guzman¹, Ma. de Pedro¹, Cecilou Bilbao¹, Honeylin Todavia¹

¹RTI, Philippines

Background: Availability of quality and timely data is crucial to effective health program management. In the case of the Philippines's national health information system, Field Health Services Information System (FHSIS), anecdotes abound on challenges to its implementation. However, there's been no purposive documentation of its nature from the users' perspective.

Methods: To build data on this, the study conducted interviews, partnered with records review, with select public health facilities, provincial and city health offices, and regional and national Department of Health (DOH). Topics discussed focused on Family Planning (FP) since availability of quality FP data is paramount to addressing increasing unmet need for FP and teenage pregnancies and for appropriate resource allocation given the upcoming devolution of procurement of select FP logistics to Local Government Units (LGUs).

Results: Results showed that despite the strain COVID-19 put on the limited health workforce, compliance to recording and reporting processes were maintained although problems on timeliness were aggravated. Integration of hospital reports to FHSIS is a challenge due primarily to absence of standard consolidation tools and reporting guidelines. This is also why extent of issues on accuracy and reliability of hospital reports cannot be fully determined. Difference in perception per reporting unit on where integration should happen was also observed. Lack of standard electronic FP FHSIS tools that facilitates consolidation and validation led to the development of excel-based tools with varying set-up depending on an area's data needs. Despite availability of e-tools, some continue to use paper-based tools due to unavailability of equipment, limited skill, or error in the e-tool itself.

Conclusion: Overall, despite these challenges, short-term solutions to address these has been implemented by the users themselves. However, long-term resolution would depend largely on support and direction from the national DOH.

Patient Experience of Using Telehealth Services during COVID-19 in Dubai Health Authority: A cross Sectional Electronic Survey

Wafa Alnakhi¹, Amal Al Balushi², Heba Mohammed³, Hamid Hussain¹, Gamal Shaker¹, Mohamed Mudawi¹, Noora Almulla³, Nabil Natafagi⁴

¹Dubai Health Authority, Mohammed Bin Rashid School of Medicine and Health Sciences, "Dubai Health Authority - Head Quarters, Sheikh Ahmed Square", United Arab Emirates, ²Oman College of Health Science- Muscat, Oman, ³Directorate General of Human Resources Development, Oman, Phone:+968-24568148", Oman, ⁴Dubai Health Authority, ⁴University of South Carolina, USA, "Department of Health Services Policy & Management, Arnold School of Public Health, University of South Carolina, 915 Greene Street, Discovery Bldg. Suite 349, Columbia, SC 29201, United States

Background and Objective: During the COVID-19 pandemic, many healthcare systems shifted to the utilization of telehealth to ensure the continuity of healthcare services (1,2,3). Hence, Dubai Health Authority (DHA), the government entity that oversees healthcare services in the Emirate of Dubai, United Arab Emirates (UAE), has adopted the telehealth model in outpatient settings. Therefore, this study aims

to examine patients' telehealth usability during COVID-19 in Dubai.

Methods: A cross-sectional study adopted Telehealth Usability Questionnaire (TUQ). A total of 64,173 participants who used telehealth services during 2020 – 2021 were recruited from the electronic medical record to participate in electronic survey from October to December 2022. The survey was administered through DHA text messaging system. The survey examined participants' characteristics and the six domains of TUQ with a Likert scale. Frequency, percentage, and weighted mean score percentages were used as descriptive statistics to analyze this data.

Results: A total of 1,535 participants completed the survey. The overall TUQ showed the mean age of users was 43.37 years (± 11.67 SD). More than half of the users were females (65.21%), the majority were married (74.46%), of a UAE nationality (83.58%), had higher education (56.68%), and were currently working (57.13%). Consultations and COVID-19-related concerns (45.14%), medication refills (19.80%), and laboratory tests (18.24%) were the main reasons for telehealth visits. Weighted means of TUQ six domains were usefulness (87.11%), ease of use and learnability (86.98%), interface quality (85.73%), interaction quality (86.44%), reliability (79.48%), and satisfaction and future use (86.44%).

Conclusion: Our study revealed high levels of usability and willingness to use telehealth services as an alternative modality to in-person consultations among the participants of the survey. Our results support the implementation of telehealth services in DHA; however, further studies are required to understand the applicability of telehealth after COVID-19 and how to further improve satisfaction.

Popul. Med. 2023;5(Supplement):A639

Education in type 1 diabetes mellitus through virtual method and its influence on metabolic control - a pilot study

Roberto Freire de Freitas¹, Sandhara Ribeiro Rodrigues¹, Marcio Araújo²

¹Oswaldo Cruz Foundation Brazil, ²Oswaldo Cruz Foundation Rua

Conselheiro Da Silva 708 Brazil

Background: Diabetes education groups exist to support self-care and can take place in many ways, including through technologies. Barriers associated with participating in face-to-face groups can be overcome with the use of digital health interventions and it is perceived that there is a knowledge breach in relation to studies that address this issue with intervention methodologies.

Objective: To develop a virtual type 1 diabetes education program lasting 12 weeks; to measure self-care and quality of life before and after the intervention and, to evaluate the effectiveness of the virtual program in the metabolic control. Method: This is a methodological study, based on a diabetes education protocol in virtual format. This protocol consisting in sending educational messages through a WhatsApp group. Before and after the intervention, clinical and laboratory data on glycemic control were collected, and the Diabetes Quality of Life Measurement Questionnaire (DQLMQ-Brazil) and part of the Diabetes Self-Care Questionnaire (DSCQ) were applied.

Results: The educational material was based on the recommendations of the American Association of Diabetes Educators, and consisted of texts, images, infographics and links. The pilot project was executed with 6 people, with an average age of 31 and average time since diagnosis of 14.6 years. There was an improvement in the quality of life score and an increase in the weekly frequency of following up on healthy eating, fruit and vegetable consumption, capillary blood glucose measurement and clinical examination of the feet. There was no statistical significance in the analyzed variables.

Conclusion: It is concluded that the diabetes education tool built is practical to implement and has increased access capacity, and can be used by various professionals and health institutions.

Popul. Med. 2023;5(Supplement):A640

DOI: 10.18332/popmed/164208

Enabling digital health access for the vulnerable and marginalized population in India

Simran Singh¹, Sana Thapa²

¹Swasti health catalyst 25, 3rd Floor, Raghavendra Nilaya, 1st Main Road,

AECS Layout, Ashwathnagar, near Rishi's Paratha Plaza Sanjay Nagar,

Bengaluru, Karnataka 560094 India, ²Swasti health catalyst

Background and objective: The vulnerable population and marginalized communities are prone to receive undignified care, lack of timely care and unresponsiveness from the health systems. The health inequities in low-resourced settings lead to a lack of access to healthcare services and lack of reliable health information. The telecare program was implemented to examine the feasibility and acceptability of using community led telemedicine models to solve for health inequalities and health illiteracy in vulnerable communities such as LGBTQ population and slum

dwellers where digital illiteracy and digital divide is significant.

Methods: The program was carried out from jul'21-dec22 in 9 different locations across 6 Indian states. Communities belonged to lgbtqia, indigenous communities, migrant workers, slum dwellers and rural population. A team of community health workers were recruited for last mile health access. They advocated and facilitated the program on-ground. Qualified nurses, doctors, counselors, welfare officers and triage-aid agents were connected digitally through a health-tech platform.

Results: Program reached over 82,000 individuals. 2,075 medical cases were treated and 508 health information calls were facilitated. There was a positive uptake of the community-lead telemedicine services among the members. Presence of community health workers on-ground earned trust among the members, changing their health seeking behavior and solved for digital illiteracy and digital divide which were the pivotal factors for failure of telemedicine models. The cost of delivering one quality medical case was estimated at inr 96, similar quality consultations are priced over inr 400 in tier 2 cities.

Conclusion: Telecare addresses health inequities and substantially bridges the access gap in low-resource and discriminated communities by providing personalized health information and building resilient healthy communities. The program demonstrated a new model of care that provides dignified and quality care to unheard voices and is scalable, adaptable and agile to other vulnerable health populations.

Popul. Med. 2023;5(Supplement):A641

DOI: 10.18332/popmed/164434

Health information system evaluation tools: a scoping review and tool development

Aisha Shalash¹, Niveen Abu-Rmeileh¹, Khalifa Elmusharaf², Yasmeen Wahdan¹

¹Birzeit University Palestinian Territory, Occupied, ²University of Birmingham Dubai United Arab Emirates

Background: The purpose of this scoping review was to collect articles or reports that describe a framework or assessment tool used to evaluate a country or program's health information system with a specific interest in the assessment of an adolescent health information system. If an assessment is not found for adolescent health, we can then assess how each was used and define the domains in each tool. We then hope to adopt a time-efficient, collective, and exclusive tool that can be used to evaluate the adolescent health information system in humanitarian settings.

Methods: A scoping review was performed to find tools used to assess health information systems. MEDLINE, CINAHL, EMBASE, and Web of Sciences databases were searched as well as the reference lists of included articles. The main inclusion criteria were that the article or report had to describe the tool or framework used to measure a health information system of a program or country. **Results:** Out of 2366 articles, 34 articles and reports were found describing ten assessment tools. The most popular tools were the Performance of Routine Information System Management (PRISM) tools by MEASURE Evaluation, the Center for Disease Control (CDC) surveillance system guidelines, and the Health Metrics Network assessment tool. The assessed main domains were resources, human resources, data sources, indicators, data management, data quality, data demand, use, and stakeholder engagement. Most assessments were adapted from the original to fit country and program needs and were used in humanitarian settings.

Conclusion: No assessment tool was found to address adolescent health information needs precisely. With the different tools found, we choose the most critical domains of each tool to adopt as an assessment tool to address the adolescent health information system. This tool will be piloted in the occupied Palestinian territories, which is currently facing a humanitarian setting.

DOI: 10.18332/popmed/164461

Methodology for diagnosis of the current state of supply chain quality management in the maternal perinatal care route in disparate rural territories

Helena Carretero¹, Lina Tafurt¹, Helena Carretero²

¹Universidad Icesi Colombia, ²Universidad Icesi

In Colombia, the Ministry of Health and Social Protection developed the Perinatal Maternal Care Route (RAMP), which seeks to guarantee comprehensive health care for pregnant women. However, when reviewing the health indicators in Colombia in recent years, negative results are perceived, especially in people from dispersed rural territories with an alarming increase in cases of maternal and perinatal mortality. Therefore, this study focused on maternal and perinatal health in dispersed rural communities, bearing in mind that they face geographic,

economic, and social barriers. The objective of this work was to define and apply a diagnostic methodology for the state of the RAMP to carry out an exhaustive analysis of the links in the chain through the Supply Chain Quality Management (SCQM) strategy in rural areas. municipalities of Santander de Quilichao and Caloto in Colombia. Descriptive-qualitative research. It included the phases of: inquire, define and ideate. A bibliographic search on SCQM analysis techniques was carried out and social innovation methodologies were used to develop this proposal. This study confirms that the RAMP can be seen as a SCQM since it was possible to identify in a transversal way the relationships and flows that exist in this way, in addition, the development of this technique allowed to recognize in a systemic way the causes that are influencing the problem. of the route to propose control actions and alarms with greater integration between the levels of care. It was found that the main problems that affect the provision of services in the RAMP are the disconnection between actors, the fragmentation of the network of service providers, barriers to entry and user recruitment, and asymmetries in quality attributes. Developing a diagnosis adapted to dispersed rural territories made it possible to propose lines of action with a territorial approach to strengthen the RAMP.

DOI: 10.18332/popmed/164372

How to evaluate health and medical apps in public health - what are alternatives to randomized controlled trials?

Laura Maaß^{1,5}, Felix Holl^{2,3,5}, Robert Hrynyschyn^{4,5}

¹SOCIUM Research Center on Inequality and Social Policy, University of Bremen, Bremen, Germany, ²DigiHealth Institute, Neu-Ulm University of Applied Sciences, Neu-Ulm, Germany, ³Institute for Medical Information Processing, Biometry, and Epidemiology, Ludwig Maximilian University of Munich, Munich, Germany, ⁴Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Institute of Health and Nursing Science, Berlin, Germany, ⁵Leibniz ScienceCampus Digital Public Health Bremen, Bremen, Germany

How people monitor their health has changed drastically during the last years since the widespread accessibility of smartphones. Since then, thousands of apps have been developed to promote health and prevent diseases. They can also improve the patient's autonomy and reduce the workload burden on health professionals. However, these apps can also have downsides, as their evidence is not always available. Instead, some studies discuss a gap in long-term evidence regarding health apps. To tackle this, many countries started to regulate medical apps (a subgroup of health apps) as mobile medical devices. In Germany, the Digital Healthcare Act has regulated the prescription and reimbursement for medical apps as digital health applications (DiGA) since October 2020. To be listed as a DiGA, medical apps must demonstrate positive medical benefits and patient-relevant structural and procedural improvements through suitable methods (e.g., randomized controlled trials (RCT)). While RCTs are considered the gold standard for evaluating causal relationships between tools and resulting health outcomes, they might not be suitable for the digital environment. Software (such as apps) is characterized by its evolving process at a rapid pace. This doesn't work well with the average 5.5 years duration of an RCT with a strict study protocol. Additionally, such extensive research is expensive and nearly impossible to finance for health technology start-ups. This workshop will argue that RCTs have limitations when evaluating health or medical apps. We will introduce the participants briefly to the three core principles (3 talks, 5 minutes each) before discussing possible alternatives. To start, Laura Maaß will present the differences between health and medical apps and why differentiation is crucial when discussing their evidence. Building on this, Felix Holl will display the regulation of medical apps in Germany as DiGA and why Germany decided to use RCTs as the primary evaluation method. Lastly, Robert Hrynyschyn will explain why RCTs have limitations in evaluating health and medical apps and what alternatives exist. Once the participants gain insights into the problem, we will divide the audience into smaller groups to collect and prioritize the challenges for assessing health and medical apps during the development, evaluation, and implementation phases. The groups will then formulate solutions and assessment designs based on this Discussion. Finally, the group's Results will be presented to the audience and discussed with the whole group. We will use the Results from the workshop for a white paper on alternative methods for assessing and evaluating health and medical apps to make the Results public to interested researchers and policy-makers outside this conference.

Workshop Objectives: The workshop's objective is to discuss the challenges of applying methods to digital health tools that weren't designed to evaluate the digital environment. Together with the participants, we aim to find alternatives for RCTs as the new gold standard for assessing digital public health interventions.

Workshop key questions: What public health challenges arise in using, evaluating, and regulating health and medical apps? How can those challenges be addressed to create a higher impact on healthcare systems?

Popul. Med. 2023;5(Supplement):A644

DOI: 10.18332/popmed/165233

Learning from digital public health interventions in practice: challenges we embraced

Laura Maaß^{1,2}, Felix Holl^{3,4,2}, Stefan Buttigieg⁵, Ihoghosa Iyamu^{6,7}, Chen-Chia Pan^{8,9,2}

¹SOCIUM Research Center on Inequality and Social Policy, University of Bremen, Bremen, Germany, ²Leibniz Science Campus Digital Public Health Bremen, Bremen, Germany, ³University of Munich, Munich, Germany, ⁴DigiHealth Institute, Neu-Ulm University of Applied Sciences, Neu-Ulm, Germany, ⁵Ministry of Health Malta, Valletta, Malta, ⁶School of Population and Public Health, University of British Columbia, Vancouver, Canada, ⁷British Columbia Centre for Disease Control (BCCDC), Vancouver, Canada, ⁸Leibniz Institut für Prävention Research und Epidemiologie - BIPS GmbH, Bremen, Germany, ⁹Institute for Public Health and Nursing Sciences (IPP), University of Bremen, Bremen, Germany

Workshop outline: Digital healthcare technologies can facilitate core public health functions, improve efficiency, and reduce costs or the burden of the healthcare workforce. Public health decision-makers, researchers, and practitioners are increasingly required to consider such interventions. However, they must grapple with multiple challenges in operationalizing digital public health (DiPH) interventions. This workshop will address some of these challenges and provide best practice examples of projects from various jurisdictions with diverse backgrounds to highlight how DiPH interventions can excel in various settings.

1. ECRA: An interdisciplinary early career research academy for digital public health Founded in 2020, the ECRA is an interdisciplinary exchange and research collaboration space for over 40 PhD- and postdocs researching DiPH. Members collaboratively produce publications or conference panels and organize workshops or skill-building lectures. Such centers are needed to support the future public health workforce to master skills essential for their career. Still, they can also be applied to general research projects to foster interdisciplinary collaborations. We will highlight encountered implementation and management barriers and how we overcame them. 2. GetCheckedOnline: An equity-centered approach to STI-testing GetCheckedOnline launched as Canada's first publicly funded comprehensive internet-based sexually transmitted infection (STI) testing service in 2014. It aims to increase the uptake and frequency of STI-testing, especially among people experiencing barriers to in-clinic STI-testing. GetCheckedOnline provides free online STI-testing in eight cities in British Columbia and has significantly increased its user-base since 2020. We will describe learnings to foster equitable access to digital STI-testing through our integrated approach to implementation, operations research, and community engagement. 3. Health technology assessment for digital health interventions/initiatives for public health (hilltop): fostering cross-country collaboration and identifying research needs. The Hilltop project initiated a cross-country collaboration between Tanzania, Rwanda, South Africa, and Germany and interdisciplinary collaboration across medical informatics, nursing, mental health, and information systems. The project team overviews the state and gaps in using HTA (for DiPH interventions) in the project countries. We will share these findings and critically assess the potential of using HTA methods in DiPH. 4. Malta's digital COVID-19 strategies: breaking infection-chains through digital public health tools COVID-19 accelerated the demand for digitalizing public health. Despite the well-needed push, the challenges facing every similar implementation will be the same, if not accentuated. We will highlight the difficulties and facilitators of Malta's digital COVID-19 strategy while focusing on the lessons learned from communicating with public health decision-makers, implementing, monitoring, and following up on Malta's national contact tracing app and Customer Relationship Management systems. Both interventions tackled the Test, Track and Trace workflows integral to Malta's COVID-19 response.

Workshop Objectives: The workshop will address obstacles and their solutions during planning, implementing, and evaluating DiPH interventions in various settings. Workshop key questions: How can we best prepare the public health workforce for the digital environment and the challenges for DiPH projects? How can we best leverage resources to develop and maintain evidence-based DiPH interventions that promote health equity? How can we effectively communicate our research results to policy-makers for a national public health impact?

Popul. Med. 2023;5(Supplement):A645

DOI: 10.18332/popmed/165264

How to achieve effective interdisciplinarity in digital public health

practice

Laura Maaß^{1,2}, Merle Freye^{3,2}, Núria Pedrós Barnils^{4,2}, Chen-Chia Pan^{5,4,2}

¹SOCIUM Research Center on Inequality and Social Policy, University of Bremen, Bremen, Germany, ²Leibniz Science Campus Digital Public Health Bremen, Bremen, Germany, ³Institute for Information, Health and Medical Law (IGMR), University of Bremen, Bremen, Germany, ⁴Institute for Public Health and Nursing Sciences (IPP), University of Bremen, Bremen, Germany, ⁵Leibniz Institut für Prävention Research und Epidemiologie - BIPS GmbH, Bremen, Germany

Their interdisciplinary nature characterizes health, especially public health: Some involved disciplines address an individual's health or set the framework for health practices (e.g., law, medicine, psychology, ethics, or sociology). Others measure health outcomes on a population level (e.g., epidemiology) or develop interventions to improve the population's health (e.g., health promotion, health management, or implementation science). Since health and public health are becoming increasingly digitalized, this adds new and essential disciplines to develop and improve evidence-based digital technologies and innovations (e.g., human-computer interaction, computer science, or engineering). Having various disciplines collaborating can offer new opportunities but also create new challenges if there is no mutual understanding of digital public health. Therefore, this skill-building workshop aims to foster awareness of interdisciplinary approaches in public health research and practice. Two presentations will set the workshop's frame and foster mutual understanding of the key terms: Interdisciplinarity and (digital) public health. Given its interdisciplinary field, public health scientists often claim to facilitate health-related interdisciplinary research and practice. However, little is known regarding whether it is merely a descriptive term or whether normative expectations are also associated with it. We emphasize that a mutual understanding of the term enables successful interdisciplinary research and practice. Therefore, the first presentation by Merle Freye will give an overview of the concept of interdisciplinarity. Building on the terms clarification, the talk will draw on the practical challenges of interdisciplinary research and best practice examples for promoting such competencies. During the second talk, Laura Maaß will describe traditional public health core functions and how they relate to other disciplines in the social, natural, and environmental sciences and humanities. Further, the talk will highlight how the extension to digital public health influenced the so-called system of sub-disciplines that form public health. We will illustrate the challenges and opportunities that arise from this complex view of (digital) public health and how to approach them accordingly. Building on knowledge gained in the first presentation, participants will hear about the need to combine discipline-related knowledge to tackle public health issues and achieve the goal of population health promotion. The participants will be invited to discuss the challenges and opportunities of interdisciplinary collaborations in three small groups after the introductory talks. The groups will focus on the challenges and opportunities of interdisciplinary collaborations during a mobile mental health apps development, evaluation, or implementation. For this, they'll receive support from experts in law, ethics, public health, health promotion, epidemiology, psychology, and human-computer interaction. Afterward, the groups will present their results in plenary and discuss how to best approach interdisciplinary practice and research and what they deem crucial requirements.

Workshop Objectives: Our workshop's primary objective is to raise awareness regarding the opportunities for interdisciplinarity in (digital) public health. The second goal is to sensitize participants to a mindset characterized by empathy and curiosity toward other disciplines.

Workshop key questions: How can one efficiently incorporate other disciplines through interdisciplinary approaches in (digital) public health projects? How can different disciplines communicate more effectively?

Human-centered design approaches to develop digital tools to enhance Indigenous health

Emma Patu¹, Cristina Ore², Alec Calac³, Timothy Mackey⁴

¹World Federation of Public Health Associations (WFPHA), New Zealand, ²University of Washington, United States, ³University of California San Diego, United States, ⁴University of California San Diego, San Diego, United States

Outline of overall workshop: The focus of this workshop is to increase capacity and knowledge of delegates in leveraging different digital tools to enhance health equity and Indigenous health objectives. The workshop is a collaboration between the WFPHA Global Health Equity and Digital Technology and Indigenous Working Groups and will begin with a short Introduction into concepts regarding digital health tools, human-centered design, and specific Indigenous health challenges

that will be co-presented by working group chairs. After the Introduction to the workshop, participants will be guided through a short co-ideation and co-design session around specific Indigenous health challenges that can benefit from digital health approaches. Delegates will be provided information on different resources, software, and tools that can be used for rapid prototyping of digital health solutions and can actively participate in the workshop by helping to formulate solutions for specific Indigenous health challenge case studies. Finally, participants will have the opportunity to present their thoughts, solution ideas, and possible prototypes to all workshop attendees and have them evaluated by workshop chairs and speakers. Using this approach, we hope to generate innovative ideas that address unique and underserved areas in global health, health equity, and Indigenous health while also building capacity by enabling participants to continue to explore digital health solutions in their own communities.

Specific Aims/Objectives: 1. Describe how human-centered approaches in digital health design and innovation can help enhance health equity and Indigenous health objectives, 2. Identify different human-centered design resources, tools, software, and methods for purposes of rapid prototyping of solutions, 3. Provide participants the opportunity to co-design digital health tools and present them for expert and group feedback. Key questions workshop will address: The key questions that will be addressed in this workshop include: (1) what type of digital health tools and human-centered design approaches have been used to address health equity?; (2) how do we ensure that the next generation of digital tools are designed purposefully for the needs of distinct communities, including specifically Indigenous peoples?; and (3) how do we incorporate concepts such as Indigenous Data Sovereignty into digital health design and commercialization in a sustainable manner.

Dealing with infodemic and health mis/dis-information: new public health organizations' proposals

Ruediger Krech¹, Fidelia Cascini², Iveta Nagyova³, Melissa Sweet⁴

¹World Health Organization, Switzerland, ²Università Cattolica S. Cuore, Italy,

³Pavol Jozef Safarik University, Slovak Republic, ⁴Croakey Health Media, Australia

In the last years and mostly during the pandemic, the proliferation of digital channels and news sources including social media has caused an overabundance of information referred to as an infodemic. It involves misinformation (information which is essentially wrong or untrue), and disinformation (information that is created to be misleading or harming). These are harmful as it can undermine compliance with public health measures, and effective mobilisation for the health risks prevention and the management of emergencies contributing to people polarisation on dangerous behaviours and social divisions. The complex problem of health mis/dis-information would require coordinated actions of all concerned stakeholders as citizens, governments, and information platforms, under the expected leadership of Public Health Organizations cooperating at a global level. A joint statement from September 2020 by the WHO, UN agencies and the International Federation of Red Cross calls for action on the infodemic by national governments and social media organisations.[1] [1] The UN describes multiple approaches taken to fight misinformation: dissemination of accurate information, partnering with businesses, working with media and journalists, mobilising civil society as well as supporting free speech.[2] [2] More recently, the WHO also published a policy brief on COVID-19 infodemic management[3] [3]. Further, WFPHA Leadership Coalition is addressing the issue of health misinformation/disinformation developing new strategic approach and tools that are going to be presented in the workshop.

Workshop description: This one-hour workshop provides an overview of new Public Health Organizations' proposals to address the infodemic and health mis/dis-information challenges. The workshop embraces the WHO policy recommendations to train health workers on these issues, to tailor digital literacy initiatives and to develop high-quality, accessible health information. Furthermore, a new toolkit designed by the WFPHA LC is presented in combination with a plan for its dissemination to the WFPH Associations and its implementability appraisal at a global level. The different perspectives of the High- and Middle-Low-Income countries are examined. In addition, the scientific community approaches to the infodemic are shown by EUPHA and its contribution to the field as well. Finally, the strategies and reactions of the digital channels and social media are reported directly by the stakeholders' experience. The audience can benefit of an inspiring Discussion with the panel of experts. [1] [4] WHO. Managing the COVID-19 infodemic: Promoting healthy behaviours and mitigating the harm from misinformation and disinformation. 2020. <https://www.who.int/news/item/23-09-2020-managing-the-covid-19-infodemic-promoting-healthy-behaviours-and-mitigating-the-harm-from-misinformation-and-disinformation>.

Addressing the Infodemic from a Health Information Equity Lens

Timothy K. Mackey¹, Elena Petelos², Tina Purnat³, Iveta Nagyova⁴, Dimitra Lingri⁵

¹Global Health Program, Department of Anthropology, University of California, San Diego, United States, ²Department of Health Services Research Care and Public Health, Research Institute Maastricht University, Maastricht, The Netherlands, ³Department of Epidemic and Pandemic Preparedness and Prevention, World Health Organization, Geneva, Switzerland, ⁴Institute for Collective Health, European Public Health Association, Slovak Republic, ⁵European Healthcare Fraud and Corruption Network, Greece

Outline of overall workshop: The focus of this workshop is to increase capacity and knowledge of delegates by providing them with the evidence, resources, tools, and support to combat health Infodemics through the lens of health information equity. The workshop is a collaboration between the WFPHA Global Health Equity and Digital Technology, the Health Technology Assessment Section of the European Public Health Association, and the World Health Organization. We will start with a short Introduction into key concepts, i.e., the infodemic, misinformation, disinformation, evidence generation and health knowledge dissemination, digital health literacy, health information equity, and then transition to a discussion of specific case studies illustrating how misinformation impacts underrepresented global communities and populations in low- and middle-income countries. After the Introduction, participants will be guided through key strategies on how to improve health information accessibility, identify specific misinformation-induced health inequalities that may target certain groups, and explore different approaches to retrieve and appraise evidence. These strategies will be used to formulate and develop effective and timely messaging and communication approaches to debunk or correct misinformation, as it occurs, in online and physical spaces alike. Delegates will be specifically provided with information on different resources, training, and community-outreach developed by the WHO, and will be given the opportunity to ideate on how to tailor these tools to interventions in their own communities. The workshop will close with a collaborative exercise among all participants to crowd-source ideas around definitions, shared objectives, priorities, unique measurements, and activities needed to specifically address the Infodemic from a health information equity lens. Using this approach, we hope to generate needed dialogue among the global health community about the need to infuse health equity into conversations about misinformation, improve access to evidence and tools to strengthen shared goals of improving information equity and management of infodemics, and contribute ideas that can improve adherence to public health measures and confidence and trust in science.

Specific Aims/Objectives: 1. Describe how addressing health information equity is critical to combatting health misinformation, 2. Identify and improve access to evidence, resources, tools, and strategies to ensure community resilience against the infodemic while also strengthening trust in science, 3. Generate shared objectives, priorities, and activities needed to specifically address the infodemic from a health information equity approach. Key questions workshop will address: The key questions that will be addressed in this workshop include: (1) how do challenges associated with the Infodemic originate from fundamental issues related to health information equity?; (2) what are some key strategies needed to concurrently address health information equity and to combat health misinformation and what is the role emerging and exponential technologies can play in these?; and (3) what do WFPHA delegates think are the key priorities in advancing this area of study and engagement to enhance health information equity and community reliance against Infodemics?

Digital Public Health Governance - navigating complex structures

Sarah Forberger^{1,2}, Merle Freye^{3,2}, Stefan Buttigieg⁴, Laura Maaß^{5,2}

¹Leibniz Institut für Prävention Research und Epidemiologie - BIPS GmbH,

Bremen, Germany, ²Leibniz ScienceCampus Digital Public Health Bremen, Bremen, Germany, ³Institute for Information, Health and Medical Law (IGMR), University of Bremen, Bremen, Germany, ⁴Ministry of Health Malta, Valletta, Malta, ⁵SOCIUM Research Center on Inequality and Social Policy, University of Bremen, Bremen, Germany

The COVID-19 pandemic is among society's most severe crises this century. The rapid transmission speed has forced countries to adapt their national healthcare systems at an unprecedented rate, with digital health playing a crucial role in universal health coverage. However, to develop its full potential, appropriate governance structures should go along with mechanisms for egalitarian, sustainable, and high-quality systems and data to tap into their full potential for population health. Therefore, this workshop addresses the following objectives: Navigation complex structures – how could digital public health governance look? Digital public health encompasses, e.g., disease surveillance systems, electronic medical records, and social health insurance payment processes. An overview of the complex building blocks of the system and the coordination of stakeholders and policies to develop, implement, and maintain a well-functioning and comprehensive health system is needed. The workshop will show how complex the system is and what it entails and discuss the role of transparency, accountability, participation, and integrity in building such a system. Nothing without data – creating robust and scalable data pipelines and platforms: Developing robust and scalable “infostructures” requires backing robust data platforms designed to empower automated reporting and, better yet, federated analysis. Moving away from existing standard tools for static analysis, e.g., Microsoft Excel, to well-designed data pipelines and platforms requires basic understanding and advanced planning. This session will outline the available technology, a basic methodology that goes into understanding your current data sources, data pipeline planning, implementation techniques supported by a data strategy and understanding what an ideal data science team looks like. No data without proper informed consent – data protection in the digital age: Digital health systems and data pipelines are inseparably associated with data. Health data processing can serve public interests and benefit individuals and society significantly. Contrarily, data protection aims to protect personal data and is often identified as one of the main culprits for innovation. Undoubtedly, the philosophy of Open Data contradicts the basic principles of data protection – especially when the pandemic unveils a structural data problem in several countries. Nevertheless, the European Data Protection Law is not as insufficient as thought. Although the solution is often reduced to the so-called informed consent, the law is more flexible as perceived in practice. The session sheds light on new solutions and challenges, showing that harmonising data flow and data protection is not a mission impossible. Helping countries to learn - comparing digital public health systems: COVID-19 worked as a catalyst to further develop digital tools to support healthcare systems. Benchmarking strategies are crucial to save resources and progress faster during the transition. This talk will present the Digital Public Health Maturity Index, a tool to assess ones digital (public) healthcare system and compare it with another country. The index encompasses the technological and legal requirements, the society's attitude towards using the applications, and the degree of implementation. The index displays the results as a score, allowing for country comparisons and thus encouraging improving their public health system and digital public health.

Precision medicine as the future of public health

Budi Sadikin¹, Jorge Guzman², Kausik Ray³, Mega Febrinora⁴

¹Institute for Collective Health, Ministry of Health of the Republic of Indonesia, Indonesia, ²Cleveland Clinic Abu Dhabi, United Arab Emirates, ³Imperial College London, United Kingdom, ⁴Indonesian Heart Association, Indonesia

Background: Precision (or personalized) medicine is defined as the application of emergent technologies to better manage patients' health and to target therapies to achieve the best outcomes in the management of a patient's disease or predisposition to disease. Used properly, precision medicine should both improve patient outcomes and deliver benefits to the health service - including reducing the cost of ineffective treatment and multiple tests. To bring precision medicine into reality, we need to understand the relevant regulatory issues within precision medicine, exploring opportunities that could further improve patient safety and outcomes, identifying issues for the state to monitor, and putting forward recommendations that would continue to support innovation. How we move from our current healthcare system to a precision medicine system is the challenge we face. We can chase how others in the world develop and implement precision medicine, primarily as a race to be first in biomedical and genomic discovery; or we can lead the world in demonstrating how precision medicine should be

responsibly and sustainably delivered. Given the tools and increased insight into health and disease, precision medicine offers tremendous opportunity to help address many of the barriers and challenges in patient's management. Precision medicine offers the ability to understand and reduce individual risk for developing various health concerns. This can support better decision-making about where to focus prevention efforts. It is well recognized that behavior change is an important aspect of many treatment plans, and also one of the most difficult. Through increased data and real time feedback, there is the potential to support more individualized behavior change that is more suited to the individual rather than a generic education program. Additionally, rather than the trial and error of therapies that are often experienced, precision medicine approaches, based on biological drivers, should be able to provide earlier diagnosis, preventing months or years of provider visits and tests, and can lead to earlier treatment and prevention of complications. Not only is there a potential to provide an earlier diagnosis, there is great potential to predict, based on use of large data sets, which intervention is most likely to achieve the desired outcomes with the fewest side effects. This has the potential to save treatment costs as well as reduce suffering and complications. The workshop session will bring comprehensive perspectives from government, hospital leader, and clinician to apply the precision medicine from theory in to practice. Workshop participants will identify how to implement precision medicine as what best fit to their field of expertise.

Insights into challenges of health interventions going digital - a perspective from human-computer interaction, law and sociology

Núria Pedrós Barnils^{1,2}, Chen-Chia Pan^{1,3}, Anke V. Reinschluessel^{1,4}, Merle Freye^{1,5}, Saskia Muellmann^{1,3}

¹Leibniz ScienceCampus Digital Public Health Bremen, Bremen, Germany

²Institute for Public Health and Nursing Research, University of Bremen, Bremen, Germany, ³Leibniz Institute for Prevention Research and

Epidemiology - BIPS, Bremen, Germany, ⁴Digital Media Lab, TZI, University of Bremen, Bremen, Germany, ⁵Institute for Information, Health and Medical Law (IGMR), University of Bremen, Bremen, Germany

Brief outline of the overall workshop: In recent years, digital technologies aiming to promote and enhance the health status of individuals and communities have emerged. Given the novelty of this junction, the traditional approaches to health interventions no longer suit the development and evaluation of digital public health interventions. With the rise of technology, public health professionals need input from related disciplines (e.g., computer science, law, sociology) to ensure the quality and impact of digital public health interventions. To support the transition to digital public health, the Leibniz ScienceCampus Digital Public Health (LSC DiPH) developed a comprehensive framework that is informed by interdisciplinary research. In the workshop, we will present how it can be used to develop and evaluate digital public health interventions, thereby highlighting the importance of the aspects that originate from related disciplines.

Specific Objectives and Component Parts: The presented workshop aims to 1) introduce the newly developed LSC DiPH Interventions Framework; 2) shed light on potential challenges public health practitioners might face when developing and evaluating digital public health interventions; 3) provide insights on how to address these challenges from an interdisciplinary perspective; and 4) demonstrate how to apply the framework on specific case studies through an interactive group activity. Key questions that the workshop will address: 1. What are the common blind spots public health professionals encounter in developing and assessing digital public health interventions? 2. Why are Human-Computer Interaction, Law and Sociology essential in developing and assessing digital public health interventions? 3. How can the LSC DiPH Interventions Framework help overcome the common blind spots public health professionals encounter in developing and assessing digital public health interventions? 4. Which specific challenges arise when applying the LSC DiPH Interventions Framework on digital public health interventions?

Key considerations in digital population health interventions

Robyn Whittaker^{1,2}, Jude McCool³, Chris Paton⁴, Lorien Abrams⁵, Dale Bramley⁶, Rosie Dobson³

¹Te Whatu Ora Waitemata, New Zealand, ²University of Auckland, Auckland, New Zealand, ³University of Auckland, New Zealand, ⁴University of Otago, New Zealand, ⁵George Washington University, United States, ⁶Te Whatu Ora, New Zealand

Digital health technologies (DHTs) have become an integral part of global public health initiatives from encouraging and monitoring vaccine uptake to

supporting self-management of long-term conditions. As these technologies have matured, significant challenges have become apparent that threaten to undermine global efforts to ensure public health interventions that use DHTs are equitable and effective. Top-down large-scale deployments of DHTs designed by and for high-income contexts risk wasting efforts and resources if rejected by the local communities who are expected to use them. Regulations, standards, and guidelines developed to support evidence-based healthcare have not yet been updated to include DHTs resulting in a largely unregulated market - a problem particularly acute in low-income settings. Our international team has diverse global experience at designing, evaluating and implementing DHTs for public health and population health benefits. It is not often that we get the opportunity to come together and discuss using these tools from a public health perspective. The purpose of this workshop is to describe and discuss current trends and future considerations for designing equitable and effective digital technologies for population health. Each presenter will provide a case study of how they have used DHTs for public health programmes in Aotearoa NZ, Pacific Islands, UK, USA, Kenya, Vietnam, Israel, and India. They will outline the current evidence base in their areas of expertise and share learnings from implementing programmes in a diverse range of contexts. The workshop will focus on how DHTs can be designed to improve health equity, particularly for indigenous populations such as New Zealand Māori, and how different contexts and countries should influence how technologies should be designed and implemented. We will address the challenge of international DHT providers entering low-income settings with monolithic applications and how governments and international regulators are moving to meet the challenge of ensuring DHTs such as wearable sensors and AI-based diagnostics are evidence-based, effective and safe. Our overall theme is that although DHTs may provide value through enhanced capacity and the ability to meet increasing consumer demand for real-time, accessible, convenient, and choice-driven health care, there remain challenges with the implementation of DHTs with respect to equity, scalability and sustainability. We also question whether transparency, local ownership, equity and safety are likely to be upheld with models of social and health entrepreneurship. We will then have a live Q&A time with our panel. There will be time for open group discussion, and we would also hope to gain further insights from participants in the workshop. Objectives: To share learnings and broaden our collaborative understanding of the challenges of designing and implementing digital health technologies for population health benefits in different contexts. In particular, we are interested in further developing the focus on equity via DHTs.

Key Questions: What have we learned about designing DHTs for equity? What are models of integration of DHTs in health systems? What are the next steps for research in this area?

Popul. Med. 2023;5(Supplement):A653

DOI: 10.18332/popmed/165749

Exploring the Use of Digital Health Innovations to Improve Health Equity: An International Perspective

Timothy Mackey¹, Marcelo Fornazin², Marcelo Fornazin³

¹University of California San Diego, Global Health Policy and Data Institute, 9500 Gilman Drive, MC: 0505, La Jolla, CA 92037, United States, ²National School of Public Health, Oswaldo Cruz Foundation, Brazil, Yara, Abuelwaffa, Health 2.0 Egypt, Egypt, ³Oswaldo Cruz Foundation, National School of Public Health, Av. Leopoldo Bulhões, 1480, Room 319, Brazil

Digital health innovations are dramatically impacting practices, services, and national health systems. Digital health can potentially expand access to health services, but it can also bring risks to users. This session will therefore discuss the multisectoral understanding of the digital health ecosystem, considering equity as a tenet of modern health systems and a crucial design consideration that needs to be contextualized to local, community, and regional health needs.

The workshop's focus is to increase delegates' capacity and knowledge in leveraging different digital tools to enhance health equity while also exploring how they align with Sustainable Health Equity goals of the SDGs and local community needs. The workshop will also offer the opportunity to dialogue with the audience about their perspectives and experiences, providing opportunities for connections that can formulate a shared research agenda on digital health innovations and health equity that can be used for capacity building in different communities.

After a brief introduction, the workshop will have three moments: (i) provocations through previously elaborated questions from a group of speakers from diverse regional representation (Latin America, the United States, and the Middle East), (ii) questions and answers from the audience to promote shared dialogue and priority setting, and (iii) final considerations of a preliminary action plan for digital health and health equity. At first, each panelist will focus on answering a leading question without prejudice to dialogue with previous presentations. In the second moment,

questions will be collected from the audience to be answered in one or two blocks with each speaker and with active collaboration and problem exploration with the audience. Finally, the speakers will weave their final considerations with provocations of future agendas on the subject, including alignment with governance, policy, and the SDGs, and seek consensus from participants using digital learning tools, e.g., online polls.

Using this approach, we hope to generate innovative ideas that address unique and underserved areas in global health, health equity, and digital health while also building capacity by enabling participants to continue exploring digital health solutions in their communities.

Specific Aims/Objectives: - Describe how digital health system design and digital health tools can enhance health equity and potential risks - Identify different approaches to evaluate technology appropriateness using an equity lens - Provide participants the opportunity to discuss digital health innovation potentials and risks specific to their own communities

The key questions that will be addressed in this workshop include the following: - How to design National Digital Health Systems with a health equity lens? What are examples of digital tools that can promote equity? - How to design D2C tools that incorporate equity in the design and approach? How can we evaluate technology appropriateness with an equity lens? - How can we use open innovation to design a more equitable health future?

100 million Brazilian cohort and the cidacs birth cohort: Record linkage national data resources

Enny Cruz¹, Julia Pescarini², Aline Rocha³, Andrea Ferreira³, Mauricio Barreto³, Enny Cruz¹, Mauricio Barreto³

¹London School of Hygiene and Tropical Medicine CIDACS keppel st United Kingdom, ²London School of Hygiene and Tropical Medicine, United Kingdom, ³CIDACS, Brazil

Brief Outline Of Overall Workshop

In this workshop, we will present the process of creating two cohorts from the linkage of routinely collected health and social data from a middle-income country. We will explain the methodology and linkage strategies to develop the 100 Million Brazilian Cohort and the Cidacs Birth Cohort, their characteristics and some applications of their use. SPECIFIC AIMS/OBJECTIVES AND COMPONENT PARTS: We aim to present the two Brazilian data resources developed at the Center of Data and Knowledge Integration for Health (Centro de Integração de Dados e Conhecimentos para Saúde, CIDACS/Fiocruz) using linked administrative dataset.

* In the first part of the workshop, we will describe operational protocols for the acquisition, management, and linkage of large-scale, nationwide, administratively collected electronic health and social records in Brazil.

* Then we will describe the 100 Million Brazilian Cohort (N=131,697,800 low-income individuals, 2001- 2018), which was initially developed to investigate the social determinants and the impact of social policies on the health of the low-income population across the whole of Brazil who apply for social benefits through the Unified Registry of Social Programs (Cadastro Único). The dynamic cohort links (i) individual-level health records, including information on birth, death, notifiable infectious diseases (e.g., dengue, Zika, chikungunya, leprosy, and tuberculosis) and their treatments, ICD-10-coded hospital admissions from both communicable and non-communicable conditions (e.g., mental health, cardiovascular disease, and cancer), and deaths coded with specific causes, (ii) community-level (e.g., local deprivation), household-level (e.g., housing quality), and individual-level (e.g., educational attainment) socioeconomic data, and (iii) intervention-related data on social policies (e.g., the Bolsa Família conditional cash transfer, social housing programme Minha Casa Minha Vida, and the improvement of access to water, the Cisternas (Wells) programs). After describing this resource, we will present the main findings of published studies.

* The second data resource that we will present is the CIDACS Birth Cohort (N=28,631,394 liveborn children and mothers, 2001-2018), which was initially developed to investigate the impact of prenatal and early life events on health-related outcomes for infants, children, adolescents, and pregnant persons in the context of social inequalities. The dynamic cohort links (i) birth records, including information on antenatal care and perinatal outcomes from the Information System of Live Births (SINASC, Sistema de Informação sobre Nascidos Vivos) with (ii) socioeconomic and (iii) health outcome-related data from the 100 Million Brazilian Cohort. This dataset has been used to produce important scientific knowledge, and a study findings will be presented.

The Key Questions That The Workshop Will Address

By the end of this workshop, the participants will be able to understand the strengths and weaknesses of these cohorts, as well as discuss the importance

of these and other routinely linked data resources to knowledge generation and informed policymaking. We will also discuss the future perspectives involving the use of routinely collected data for research.

Analysis of reasons for rejection of biological specimens at national health laboratory service - Dr George Mukhari Tertiary Laboratory

Scelo Khumalo¹

¹Sefako Makgatho Health Sciences University, South Africa

Background and objectives: Clinical laboratories play an enormous role in appropriate and reliable medical decision making, given that a large proportion (70-80%) of diagnoses are based on laboratory tests. To ensure reliability of patient Results and avoid reporting of erroneous Results, quality indicators detecting laboratory errors are required. "Laboratory error" is defined as any defect in the testing process, with a reported frequency of 0.012-0.6%. Total testing process in the laboratory comprises of three phases: the pre-analytical phase, analytical and post-analytical phase. This study aimed to identify reasons for rejection of biological specimens at Dr George Mukhari tertiary laboratory. Objectives was to identify and classify the causes of biological specimen rejection, to identify areas where improvement is necessary, as well as to advise on preventative strategies. **Methods:** This was a retrospective study conducted in the department of Chemical Pathology at Dr George Mukhari Academic Hospital, Pretoria, South Africa. Data regarding specimen rejection were extracted from the laboratory information system from January to December 2019.

Results: From a total of 2463572 specimens received during the study period, 81687 were rejected, Resulting in a rejection rate of 3.3%. The rejection rate per laboratory was as follows: chemistry, 54%, haematology, 25%, virology, 13%, microbiology, 8%, and cytology, 0.15%. The main reasons for rejection were old specimens, wrong specimens, and haemolysis, accounting for 30%, 15% and 13% respectively. Community health centres showed the highest number of rejected specimens (30%), with the least (2%) from the paediatric outpatients department. **Conclusions:** Sample integrity was found to be the major reason for samples being rejected; this included old samples, haemolysed samples, followed by incorrect samples and insufficient samples received by the laboratory. The highest number of rejected samples was from the community health centres, suggesting a need for improvement in specimen handling and transportation from these sites.

Modern doctoral program in public health and social science in Georgian universities

Natia Skhvitadze¹, Tamar Lobjanidze², Mariam Lobjanidze³, Nino Chikhladze⁴

¹National Center for Disease Control and Public Health, The University of Georgia, Georgia, ²School of Health Sciences, The University of Georgia, Georgia, ³School of Health Sciences, University of Georgia, Georgia, ⁴Faculty of Medicine, Tbilisi State University, Georgia

Main challenge for academic programs is to respond to the needs of the healthcare sector faced during pandemic. Social determinants constitute about 50% of known risk factors and behavior strongly influence a burden of disease. To improve population health and to mitigation potential threats it is necessary to know health risks that are shifted from social and behavioral spheres. Modern models of public health study are more social driven and meets demand of healthcare system to improve response to potential threats. These lead academic programs to change teaching approach, include multidisciplinary and intersectoral collaboration and tackle social determinants of health. Thus, project "Doctoral Programmes in Public Health and Social Science" (DPPHSS) was initiated in the frame of Erasmus+ programme. Georgian High Education Institutions (HEIs) were participant of this project. The aim was to create modern doctoral program in public health and social science to prepare workforce equipped with knowledge and skills of the proper understanding of social component. It was initiated a cross-sectional, quantitative survey. The study was conducted among stakeholders: faculty, respective doctoral and master students, in total 60. Data were taken in one shot measurement during the dissemination event of the DPPHSS in 2021, using questionnaire. According Results several courses, most important for the public health doctoral programme are Social and behavioral aspects of public health (35%), Health promotion (35%), and Advanced epidemiology and statistics (30%). 75% of respondents advice to upgrade PhD programme according to the current pandemic needs to avoid health services disruption. Hence, in late 2021 was created modern doctoral programmes in public health and social science at the Georgian HEIs (The University of Georgia,

Tbilisi State University). Consequently, integration of social science in the public health programme contributed to better health care and social services provision and mitigate negative impact of pandemic.

Strengthening ethics in Ebola research: a toolbox developed with and for limited literacy adults in Ebola-affected countries

Elysee Nouvet¹

¹Western University, Canada

Introduction: Clinical research in West Africa routinely enrolls adults with a low level of literacy, and with no previous research experience. Such research expanded substantially in Ebola-affected countries, following the 2013-2016 Ebola outbreak (Sierra Leone, Liberia, Guinea). The purpose of this study was to develop for and with potential participants with low levels of education, means and tools to support their informed consent (or refusal) to engage in clinical research. **Methodology:** The study involved intersectoral, multi-country collaboration, notably with Ebola survivor associations and National Research Ethics Committees, to plan, develop and pilot an open access toolkit to support ethical clinical research in public health emergencies. A pilot test of the toolbox was done in Guinea using local languages (Sussu and Dioula).

Results: Participatory design of the toolbox Resulted in more audio-visual materials than initially intended, and successful piloting of the toolbox in collaboration with the Ebola Survivors Association of Guinea (May 2021). Pilot workshop participants, including women and men, and individuals aged 18 to over 70 years of age, appreciated having the opportunity to reflect collectively on benefits and risks of participating in EVD research. The use of recognizably African cultural dynamics and values in visually engaging video and poster tools was effective in instigating animated Discussion and building trust in research, but requires a facilitator guide to support effective use.

Conclusions: This toolbox will be important to disseminate among health researchers, anthropologists, members of Associations of Ebola survivors and communicators, researchers, ethics board members, civil society leaders who wish to support potential participants to better understand, discuss, prepare for, and manage their participation in clinical research projects with a particular focus on EVD-affected countries. Skilled facilitation of workshops using the tools as a point of departure for discussions is recommended.

Primary Health Care Centre, Region Stockholm, Stockholm, Sweden,

¹⁰Department of Molecular Medicine and Surgery, Karolinska Institute,

Stockholm, Sweden

Background and Objectives: There are few population-based studies on the academic achievement of children with specific congenital anomalies. In this study, we aimed to evaluate the academic achievements of children born with major congenital anomalies compared to children without major congenital anomalies and whether educational achievements are associated with sociodemographic factors.

Methods: We performed a population-based study including 401544 children in Finland, graduates of the compulsory school who applied to secondary education. We used health data from the Finnish Register of Congenital Malformations for children born from 1995 to 2002 who had a recorded major congenital anomaly linked with education data from the Finnish Ministry of Education and Culture. We used a generalised linear regression to compare the mean grade differences of children with major congenital anomalies and 'All anomalies' subgroup, included children with major congenital anomalies, chromosomal syndromes, and multiple

anomalies, with reference children.

Results: Children with major congenital anomalies were significantly less likely to apply for further education than reference children (OR, 4.13; 95% CI, 3.92-4.36). For most congenital anomalies studied, children born with congenital anomalies had academic achievements similar to the reference children. For all anomalies subgroup, children with congenital anomalies were at a higher risk of academic underachievement than reference children. Among children with congenital anomalies, male sex, lower maternal educational levels and younger maternal age were associated with significantly lower academic achievement.

Conclusions: Most studied congenital anomalies were not associated with lower educational achievements for children who applied for further education. Nevertheless, the grade means were significantly lower in all children with major congenital anomalies that included non-isolated anomalies and for children with selected isolated anomalies. A continuous need for efforts to improve educational outcomes in children with major congenital anomalies while considering sociodemographic background is apparent.

DOI: 10.18332/popmed/164924

Inter Professional Education (IPE) and team-based practice in Africa: the missing link

Godwin Aja¹

¹Association of Schools of Public Health in Africa, Philippines

Background and Objectives: Interprofessional education (IPE) is a unique model of educating students for careers in the health sector, where collaboration and teamwork are critical skills required to maximally address the health needs of society. However, it seems that the words, "collaboration" and "teamwork" in the IPE concept is often preferentially (mis)applied, to suggest collaboration and teamwork with mostly professionals within the clinical/institutional setting and does not usually include other "professionals" associated with the health system. This paper highlights the need to broaden and diversify the operational definition and application of IPE to emphasize collaboration and teamwork with extra-professionals, super-professionals and the supra-professional to optimally and holistically address the health needs of the community to ensure universal health coverage.

Methods: This is a conceptual paper.

Results: The health system is bigger than the healthcare subsystem. Therefore, interprofessional education should not only be about the professionals in the field of medicine or nursing or medical laboratory science but also other professionals involved in "addressing the priority health concerns of the community, region, and/or nation they have a mandate to serve." Collaboration and teamwork with extra-professionals, super-professionals and the supra-professional are key to addressing human health needs at both the institutional, clinical and community levels.

Conclusions: There is a missing link in the definition and operationalization of the concept of interprofessional education. The health sector is complex, diverse and encompasses other professionals, thus, requiring health professionals to work together with other stakeholders (particularly communities and policy makers) to effectively and efficiently provide need-based health to Africans. There is the need to broaden and diversify the operational definition and application of interprofessional education of students to emphasize collaboration and teamwork with extra-professionals, super-professionals and the supra-professional to optimally and holistically address the health needs of the community and to ensure universal health coverage.

DOI: 10.18332/popmed/164966

Training of health professionals to implement the overweight and obesity reduction policy

Sheila Lindner¹, Dalvan Campos², Deise Warmling³, Carolina Henn⁴, Elza Coelho³

¹Universidade Federal de Santa Catarina (UFSC), Brazil, ²Universidade do Planalto Catarinense (Uniplac), Brazil, ³UFSC, Brazil, ⁴UFSC, Brazil

Excess weight reflects a relevant public health problem in Brazil. Between 2003 and 2019, the proportion of overweight adults rose from 43.3% to 61.7%, with the prevalence of obesity rising from 12.2% to 26.8% (BRASIL, 2019). Primary Care has the role of developing prevention and care actions for overweight and obese users, in addition to promoting adequate and healthy eating. Objectives: To present the experience of designing and offering a specialization course in the distance modality, aimed at health professionals in Primary Health Care. Methodology: This is an experience report on the specialization course "Health Care for People with Overweight and Obesity".

Results: The course was structured around three axes: I. Recognition of Overweight and Obesity in the Context of Primary Health Care; II. Actions to Approach Overweight and Obesity in Primary Health Care; III. Attention to people with overweight and obesity in the cycles of life. As a pedagogical proposal, the constructivist and problematizing methodology was adopted, with evaluative activities established from challenges linked to the professionals reality. There were 713 professionals who completed the course so far, with an average age of 39.7 years and most of them female (81.9%). Regarding race/ethnicity, 48.9% were white, 48.8% black and brown. Graduates came from the five regions of the country, 38.8% from the Northeast, 30.6% from the Southeast, 14.5% from the South, 8.5% from the North and 7.6% from the Midwest. As for the professional category, nutritionists predominated (41.5%), followed by nurses (24.6%), physical education professionals (12.8%), physicians (6.3%), psychologists (4.7%), PHC managers (4.0%) and other health professionals (6.1%). Professionals reported that the course contributed to the qualification of prevention and care practices for overweight people in primary care.

A capacity development framework for research ethics committee administrators

Mutshidzi Mulondo¹, Joyce Tsoka-Gwegweni¹, Perpetual Chikobvu¹

¹University of the Free State, South Africa

Background and Objectives: Little research has been done on research ethics committee administrators' capacity development, leading to a lack of uniform requirements for this role, and few training opportunities. The role may be related to administration, but it is integral to the smooth running of research ethics committees that oversee global health and scientific research studies. This study proposed and validated a capacity development framework for research ethics administrators in South Africa using a Delphi survey on ethics experts to reach a consensus.

Methods: The Delphi method was applied among research ethics experts from South Africa and abroad through an anonymous online questionnaire.

Results: In total, 23 experts were approached to participate in the study, with 12 and 13 experts responding and participating in the two Delphi Survey rounds, respectively. The results of the second round showed that 67% of the experts confirmed that administrators require basic, entry-level training at the level of a Bachelor's degree to be able to fulfill their duties. Nearly 83% of the experts confirmed 'REC administrator' as the appropriate title for this profession. Conclusions: A capacity development framework was designed focusing on the following aspects: training, standard operating procedures, infrastructural upgrades, administrative systems, harmonising procedures, and improving information sharing in order to better capacitate administrators. Research ethics administrators need to be capacitated in various ways, comparable to the training received by committee members who review studies so that they are better placed to operate in and respond to the rapidly developing world of global health, research, and research ethics review.

Serious game: educational technology for nurses of Primary Health Care

Lucimare Ferraz¹, Paola Silva²

¹Santa Catarina State University (UDESC), Brazil, ²Universidade do Estado de Santa Catarina (UDESC), Brazil

Background and Objectives: Educational games are technologies that seek to ensure the engagement and involvement of their players, in a teaching-learning process through the game in a differentiated and dynamic way. The objective of this study was to develop a serious game on the prevention of neonatal mortality, as an educational technology for Primary Health Care nurses. Methods: Methodological research, developed in two stages: 1 - search, selection and definition of game content; 2 - development of the serious game, in the stages: Concept, Pre-production or Planning, Prototype, Production, Alpha, Beta and Gold Phase.

Results: the content of the game are real cases of neonatal death, classified as preventable, and which have already been investigated by the Municipal Committee for the Prevention of Maternal, Child and Fetal Mortality. For the selection of cases, an e-Delphi consensus panel was developed, with five members of the committee, who after analysis answered a Likert Scale: (0 - nothing relevant, I don't see the need to include; 1 - slightly relevant, but can be included; 2 - relevant, this could be it; 3 - very relevant, it would be very good to include; 4 - essential, must be included). The three cases selected to compose the content of the game

were: newborn affected by maternal hypertensive disorders, newborn affected by maternal infection in the genital tract and newborn affected by isthmus-cervical incompetence. Thus, in the serious game, the player creates his Avatar (a nurse), who is faced with the cases, being instigated to choose the best conduct of care for the pregnant woman. Considerations: we believe that it is necessary to innovate in teaching strategies, through attractive and interactive processes, based on real situations that allow active learning, reverberating in a qualification of the Primary Health Care professional for adequate prenatal care.

Assessment of knowledge gaps about ionizing radiation among public health specialists in Lithuania

Donatas Austys¹, Karolina Ščeliokienė², Rokas Arlauskas², Rimantas Stukas²

¹Department of Public Health, Institute of Health Sciences, Faculty of Medicine, Vilnius University, ²Department of Public Health, Institute of Health Sciences, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

Background and Objective: Ionizing radiation is widely used in various areas of human life. Despite its benefits, it is an important risk factor to health. Taking into account the recent nuclear threats in Europe, the aim of this study was to assess the knowledge of Lithuanian public health specialists about ionizing radiation. **Methods:** This study included 300 public health specialists working in municipal public health offices of Lithuania. In 2020, an anonymous survey was conducted. Levels of knowledge about ionizing radiation were calculated. Respondents who could answer less than 5 questions of 13 correctly were assigned to "insufficient knowledge" group. Distribution of the respondents by the level of knowledge about ionizing radiation and sociodemographic groups was assessed.

Results: The level of knowledge about ionizing radiation was insufficient among the 94.0% of the respondents. Distribution of the respondents by the level of knowledge was similar among the respondents with different gender, age, type of place of residence, marital status, level of education, income ($p > 0.05$). There were no respondents who could correctly indicate the most effective personal protection measures against penetrating ionizing radiation, internal exposure to ionizing radiation, there were no respondents who could correctly indicate medical procedures which cause the highest doses of ionizing radiation, also what happenings are accounted as nuclear and radiation accidents and incidents. Most of the respondents stated that they lacked information about radiation induced by various medical procedures, protective equipment, actions that have to be proceeded in case of accidents, accident prevention and consequences elimination plan, and information spreading in case of an accident.

Conclusions: 9 out of 10 public health professionals have an insufficient level of knowledge about ionizing radiation. This emphasizes the possible threat to the public health which should be assessed across the Europe.

Keywords: ionizing radiation, public health, knowledge, awareness

Implementing Health-Promoting Schools - Focus on ergonomics: are we verifying the effectiveness of awareness educational programs? A pilot study on the experience with middle-school children

Sara Pani¹, Fabrizio Gaccetta², Federica Cadoni³, Andrea Salda³, Arianna Liori³, Paolo Contu⁴

¹Department of Medical Sciences and Public Health, University of Cagliari, Monserrato, Italy, ²Bachelor Program in Health Care, University of Cagliari, Monserrato, Italy, ³Department of Medical Sciences and Public Health, Specialization School for Hygiene and Preventive Medicine, University of Cagliari, AOU Cagliari, Italy, ⁴Department of Medical Sciences and Public Health, University of Cagliari, Italy

Background and Objective: Ergonomics programs addressed to children and school-community fit the Health Promoting Schools (HPS) framework. Beyond the integration of ergonomics in curricula, important aspects regard the evaluation of the appropriateness and effectiveness of the programs. A correct evaluation of effectiveness is crucial to guide resource allocation, an essential step to implement and sustain the HPS approach. With the present pilot study, we aimed to evaluate the effectiveness of the program proposed to a sample of school children in the metropolitan area of Cagliari. **Methods:** The awareness educational program was designed along the lines of the National Institute of Work Accident Insurance (Italy) scheme and proposed to 260 middle-school children. The program is divided into three phases: i) assessment of students' background, ii) displaying of the training modules, iii) evaluation of conceptual understanding. For this purpose, we used pre- and post-intervention questionnaires.

Results: The results show a substantial improvement in the percentage of correct responses in the post-intervention, confirmed by the chi-square test, for questions regarding general concepts about ergonomics, backpack weight, and handling. On the other hand, some questions show a pre- and post-intervention continuity in terms of percentage of correct answers. We can divide them into two categories: a) questions to which the students already answered well (basic rules of polite postures); b) questions to which students often answered incorrectly, both before and after the intervention (illustrations; sequences). **Conclusions:** Effectiveness evaluation led us to a necessary re-evaluation of topics, form, and clearness of the questions posed, as well as of the teaching style. Adapting the program to the educational, environmental, and cultural context seems to be crucial for maximizing effectiveness. This pilot study demonstrates that the cultural gap relating to health and safety at school might be reduced with dedicated and tailored programs for school children and community.

DOI: 10.18332/popmed/165061

Exploring doctors' trade-offs between management, research, and clinical training in the medical curriculum: a discrete choice experiment in southern Africa

Jacqueline Wolvaardt¹, Astrid Turner¹, Mandy Ryan²

¹School of Health Systems and Public Health, University of Pretoria, South Africa, ²Health Economics Research Unit, University of Aberdeen, United Kingdom

Background and Objective: Public health requires doctors to fulfil roles that extend beyond that of a clinician. There is consensus that management and research training in medical curricula will reinforce evidence-based practices. The study aimed to establish how much clinical activity training time doctors in southern Africa would give up for time spent on research and management training, as well as possible teaching methods. **Methods:** A discrete choice experiment (DCE) was used. Five attributes were included: i) management content; ii) research content; iii) teaching method iv) placement; and v) clinical training hours in a week. Respondents were presented with 10 choice tasks generated from a D-efficient design. A resistance to change-beliefs scale assessed respondents' preference for tradition or change. Demographic information was collected to assess observed preference heterogeneity. Analysis of the DCE data was based on the Random Utility Maximization framework using variants of the multinomial logit model. Willingness to Give Up Time (WTGUT) was estimated for all attributes i.e., how many hours respondents would be willing to give up from the current 40 hours clinical training to be used for management and/or research training instead. The online pilot DCE survey was sent to 50 medical doctors in September 2022.

Results: Parameter estimates suggested face validity in terms of direction of preference. Relative to no management training, respondents preferred all other levels of content. There was a preference for students to learn how to use, not do, research. Relative to face-to-face teaching at the beginning of the curriculum, respondents preferred the hybrid method throughout all years. However, WTGUT estimates lacked face validity and respondents did not distinguish between clinical training levels.

Conclusions: Pilot study findings suggest the clinical training levels did not push individuals to their maximum. Revised levels will have to be included in the main study in 2023.

DOI: 10.18332/popmed/165078

The discrepancy of premortem clinical and post-mortem autopsy of lung pathologies in under-five deaths and the reasons of discrepancy among cases included in CHAMPS research, a case series study

Haleluya Leulseged¹, Nega Assefa², Merga Dheressa³, Addissu Alemu⁴

¹Haramaya University, Ethiopia, ²Haramaya University, Harar City, Ethiopia, ³Haramaya University, Harar city, Ethiopia, ⁴Haramaya University, Harar, Ethiopia

Background: In Ethiopia, modern medicine was started in 1886 G.C and health professionals have been treating patients using different diagnostics algorithms, but there is a limited practice of examining post-mortem autopsy results and thinking back on the certainty of the diagnosis made for the patients before death. Conducting diagnostic discrepancy studies is important to understand the gap that exists in the clinical diagnosis and modify the diagnostic algorithms to give better and appropriate treatment.

Methods: In this research, a formal, non-consecutive clinical case series study of under-five deaths included in the autopsy study between October 2019 and April 2022 was conducted. The premortem clinical diagnosis and post-mortem

pathological diagnosis of the lung was compared for each case, and 02 physicians evaluated the results separately for concordance and discordance of diagnosis. McNemar test was used to see if there is a statistically significant difference between the premortem clinical diagnosis and post-mortem pathologic diagnosis of each case. P-value < 0.05 was considered statistically significant. Cohen's kappa was also calculated to see the inter-rater variability. The reason for concordance and discordance in diagnosis was analyzed case by case for all under-five deaths included in this research by 02 separate senior physicians.

Results: The magnitude of diagnostic discrepancy was 34% (95% CI: 20%-47%) and Cohen's kappa Results was: 0.079. Reasons contributing to diagnostics discrepancy were: Case analysis problem (knowledge gap or compression problem) in 35.5%, Problem in consultation and teamwork in 35.5%, Documentation problem in 10%, Unavailability of diagnostic investigations in 8%, Communication gap between health facilities in 6%, Access to health facility in 3% and Work culture in 1%.

Conclusions: The magnitude of misdiagnosis of cases is very high, and interventions should be implemented on the most common causes of diagnostics discrepancy to yield a better diagnosis of diseases by clinicians.

DOI: 10.18332/popmed/165089

The terrible "C word": Dismantling coloniality and hegemonic structures in health education

Danielle Fernandes¹

¹University of Ghent, Belgium

Background: There is increasing recognition of hegemonic structures in global (public) health, from its colonial legacy to contemporary decision-making and governance. Power structures are often perpetuated through health education that instils Eurocentric perspectives and methodologies. While public health academics have long called for the decolonization of health education, there is limited evidence of such initiatives in European higher education institutions. With this gap in mind, a student-led project was launched within the University of Ghent to examine and address hegemonic structures in health education. The aims of the project were to (I) co-develop recommendations to dismantle power structures within the university, and (II) assess the implementation of these recommendations. Methods: An exploratory study was conducted consisting of a series of interviews and workshops with students and staff of the University of Ghent's Medical Faculty from February - August 2022. A co-creation approach was used to co-develop a set of actionable recommendations. These recommendations were tested, and a qualitative inquiry was conducted to explore the perspectives of students and staff regarding the acceptability and feasibility of these initiatives. Results: The project highlighted three focal areas for change; (I) diversification of teaching staff, (II) decolonisation of curriculum, and (III) North-South equity. A set of targeted policy recommendations were formulated, with a select few being tested, such as digital learning to include foreign guest lecturers, sensitisation courses, buddy programmes for North-South knowledge exchange, and sensitisation for students going abroad. Implementation barriers and facilitators were highlighted, including the importance of student engagement and the need for systemic changes.

Conclusions: This project effectively moves the decoloniality discourse in academia from rhetoric to action. The findings can inform efforts to train a new generation of health professionals that are better equipped to address power dynamics and achieve equity in public health.

Movement from knowledge-based to competency-based MPH curriculum in the United States

Laura King¹

¹Council on Education for Public Health

Background and Objective: In 2016, the Council on Education for Public Health (CEPH), the accrediting body for schools and program of public health in the United States and worldwide, adopted a competency-based approach as the foundation for the MPH curriculum, replacing a disciplinary-based, five core knowledge area (i.e., biostatistics, epidemiology, health services administration, social/behavioral sciences, and environmental health) approach. Prior to 2016, accreditation criteria required students to "complete sufficient coursework to attain depth and breadth in the five core areas of public health knowledge." In practice, all programs addressed this expectation by requiring at least one distinct class in each of the five knowledge areas. These five classes comprised the "core curriculum." The 2016 accreditation criteria define a set of 12 foundational learning objectives and 22 foundational competencies for the MPH, with no

specific references to core areas or disciplines. This presentation will focus on the evolution of the core curriculum completed by all MPH students five years after these changes were adopted.

Methods: Accreditation self-evaluation documents, appendices, and university websites accessed between March and May 2020 were reviewed and curricula were coded as A) Retained five core course structure, B) Added/changed courses, or C) Integrated courses.

Results: Results indicate that only 10% of programs have retained the pre-2016 model of curricula, and 11% of programs have pursued complete integration of the core curriculum. Nearly 80% have modified the core curriculum by retaining some discipline-specific classes and adding new non-discipline specific core classes. The most frequently added classes are those in program planning, implementation, and evaluation; research methods; and general Introduction to public health. The median number of required classes went from five in 2016 to seven in 2021.

Conclusions: A discipline-based curricular approach is not the preferred method in a competency-based learning model.

Development of innovative strategies to evaluate teaching-learning processes in public health

Edlaine Villela¹, Regiane Paula¹

¹São Paulo State Health Department, Brazil

Background and Objective: Education and communication in health surveillance have been taught in a very conceptual way in postgraduate programs, without reflection on health practice and return to society. The objective is to transform the way of evaluating a postgraduate course, allowing the use of technological resources to innovate in the area of public health and disseminate the materials prepared to health professionals and the community in general. Methods: The elaboration of the audiovisual materials was carried out by 27 students in 2021 from the Postgraduate Program in Sciences of the Disease Control Coordination/ So Paulo State Health Department to approach content of public health during the discipline of Education and Communication in Health Surveillance. As a way of applying active Methodology in the evaluation process, the elaboration of audiovisual materials was proposed. The theme was chosen by students, covering concepts and fundamentals of health education and communication.

Results: The group addressed the themes: Patient safety; COVID-19 in schools; Vaccination; One health; and HIV prevention, due to the relevance of the theme and its applicability in the practice of health surveillance. Therefore, it is extremely important to understand the subject in the work routine, aiming at improving health services. The produced videos were based on different methods, popular on YouTube. Audiovisual recordings were presented in the classroom along with an explanatory report of the activities carried out. In addition, the materials produced were posted on the YouTube channel of the Coordination of Disease Control, which allow the dissemination the of knowledge in public health. Conclusions: The use of digital technologies facilitated the learning process and effective communication. It provided innovative views on the same subject, presenting specific contents in a didactic way. The partnership between innovation and creativity made possible to assimilate the application of health surveillance content.

Student experiences and perceptions of content and learning processes during the fully online Postgraduate Diploma in Public Health

Tiaan Eksteen¹, Sean Patrick¹, Liz Wolvaardt¹

¹University of Pretoria, South Africa

Objectives: Describe enrolled students' experiences regarding learning about public health online and perceptions about content and the learning process. Study design: A descriptive cross-sectional design.

Methods: A 52-item closed-ended online questionnaire was sent to Postgraduate Diploma in Public Health (PGDipPH) students enrolled from May 2020 to March 2021 (N=775), and who had completed at least two modules. Mean Student Experience Scores (SES) and an Overall Student Experience Score (OSSES) were calculated. Logistic regression was used to determine associations between demographic variables and SES for each variable.

Results: The response rate was 31% with majority (74%) being female aged 35-40 years. Most (97%) respondents agreed that modules provide multiple activities to enhance learning. Similarly, 92% agreed that multiple assessment strategies and innovative technology actively engages them in the learning processes. The 31-34-year age group was more likely to have a lower SES for opportunities for

interaction and communication compared to the 20–30-year age group (OR 0.26, 95%CI 0.07-0.90, $p=0.028$). Respondents aged 31-34 years were more likely to have a lower SES on regular feedback regarding their performance throughout the modules compared to those aged 20-30 year (OR 0.32, 95%CI 0.11-0.88, $p=0.028$). Respondents agreed that their overall experiences of the PGDipPH were positive, OSES=37.66 (SD=3.70).

Conclusions: Results shows that the online PGDipPH provides multiple activities to strengthen student learning and that multiple assessment strategies engages students in learning processes. The overall experience of the programme is positive; however, strategies of feedback for learning and feedback of learning need further study.

New competences in MBA for healthcare programmes on the example of digitization

Piotr Szykiewicz¹, Janusz Strużyna²

¹Collegium Prometricum - The Business School for Healthcare, Poland,

²University of Economics in Katowice, Poland

Relevance: Digital competences significantly affect the ability to use the opportunities offered by digitization [Topol, 2019]. The implementation of integrated care [Goodwin, 2016]. The efficiency of using digital means of communication turned out to be particularly important during the pandemic (Clement et al., 2021). Context and Aims: Competencies can be defined as characteristic employees attributes, that helpful for understanding the current and future performance, attitudes and behaviours of employees [Grant and Baden-Fuller, 2018]. Digital competences are the attributes of the employee that allow the use of digital devices and software in a manner consistent with their capabilities, but subordinated to the users needs. Digital competences of employees are shaped in two ways. The first concerns the competence to operate digital devices for the needs of everyday life. The second way of increasing the digital competences level Results from employee improvement processes as part of professional requirements. The overlapping of digital life and professional competences is a fact and has positive and negative consequences.

Findings: Researchers analyzing digital competences have distinguished many possible ways to indicate their comprehensiveness and complexity. In the development of the tool for assessing digital competences of medical workers, an appropriately adapted model indicated in the work of Laar [Laar 2018] was used. The next stage of work on the development of digital competences of medical workers should be the development of appropriate training programs. Innovative Contribution to Policy, Practice and/or Research: The current state of knowledge shows that digital competences are not a simple sum of their components. Both the importance and complexity of the phenomenon of digital competences mean that they should find their place in the MBA in Healthcare curriculum.

Field epidemiology training program in West African Portuguese speaking countries: building capacity while strengthening health systems for health surveillance and outbreak response

Mohsin Sidat¹, Inês Gonçalves², Isabel Araújo³, António Delgado³, Maria Mendonça⁴, Paulo Ferrinho^{5,6}

¹Faculty of Medicine, University Eduardo Mondlane, Mozambique, ²Instituto de Higiene e Medicina Tropical, Universidade Nova de Lisboa, Portugal,

³Universidade de Cabo Verde, Cape Verde, ⁴Instituto Nacional de Saúde Pública, Cape Verde, ⁵Instituto de Higiene e Medicina Tropical, Portugal,

⁶Universidade Nova de Lisboa, Portugal

Introduction: In 2020, the European and Developing Countries Clinical Trials Partnership and Africa CDC announced funds for Training of epidemiologists in sub-Saharan Africa. In response, a consortium was established which included African and European Universities, National Institutes of Public Health and Research Centers. This consortium proposed a project to implement a Masters in Field Epidemiology offered via blended-learning platforms by the University of Cape Verde. Thus, this presentation is to share experiences of a first ever in the world offer a blended-learning advanced field epidemiology training, integrated into the National Field Epidemiology Training Program (FETP) coordinated by the National Institute of Public Health of Cape Verde.

Methods: The overall project will be described as well as processes in developing the curriculum and its accreditation at different levels (including Higher Education Accreditation Authorities in Cape Verde), students recruitment strategies,

establishment of International Steering Committee among others. The field training sites accreditation, processes to identifying teachers and tutors among other key aspects of advanced FETP delivery will be presented.

Results: A total of 55 candidatures were received and 15 were selected (6 from Cape Verde, 6 from Guinea-Bissau and 3 from São Tomé and Príncipe). Through a consultative process and field visits, tutors were identified for each student in their country of origin. Field training sites to enhance experiences and capacity of trainees in health surveillance and outbreak response were chosen. The expected outputs from field training were defined.

Conclusions: The practical training in the countries of origin complemented with theoretical training offered online will allow better retention of the trained cadres in their countries of origin and contribute for health system strengthening. The program will contribute with learning and teaching materials in Portuguese and enhance a cohort of Portuguese speaking African epidemiologists.

Measuring student engagement in a fully online programme in public health

Jacqueline Wolvaardt¹, Mari Wyk²

¹School of Health Systems and Public Health, University of Pretoria, South

Africa, South Africa, ²University of Pretoria, Pretoria, South Africa

Background and Objective: The maximum period of study for a Master of Public Health degree at our university is two years (part-time). The majority of students works full time and the compulsory attendance of modules usually far exceeds the number of leave weeks that our students routinely have. The entry requirement is broad and does not require a previous degree in public health. The decision was therefore made to include all the foundational modules in a fully online postgraduate diploma in public health and make this programme an entry requirement for the Master programme. One concern was whether fully employed mature students would engage in online learning.

Methods: A document review was done of the all offerings of the first module in the curriculum in 2022. The number of academic discussion posts (excluding group submissions), academic emergency posts and social posts were calculated as a percentage of enrolments. Similarly, the completion of the three possible achievement badges was calculated. A Welcome Badge was for all those who introduced themselves; A Corona Badge was awarded to those who achieved at least 50% for in-video assessments, and a Calculus Badge was for those who achieved 75% for statistics-related quizzes.

Results: A total of 970 students were enrolled in one of the six modules that met the inclusion criteria. The engagement rate in academic discussions was 2 115% (or a total of 20 522 posts). The engagement rate of students who posted in the Emergency Room (a discussion board to post problems and receive help) was 250%. There was less engagement in the social space/coffee chat room (110%). The success rate for one or more of the three possible badges was 71% (average).

Conclusions: A fully-online programme in public health that is designed (and rewards) online engagement can ensure student engagement.

⁵Department of Public Health and Infectious Diseases, "Sapienza"

University of Rome, Italy, ⁶Department of Health Promotion, Mother and

Child Care, Internal Medicine and Medical Specialties, University of Palermo,

Italy, ⁷Department of Health Promotion, Maternal-Child, Internal and

Specialist Medicine, University of Palermo, Italy

Primary Health Care (PHC) service management is one of the most important job opportunities for Public Health (PH) specialists. Despite this, according to a previous needs assessment survey, the topic of PHC is not included in the educational programs of 70% of specialization schools in PH in Italy and more than 80% of PH residents declare to have very little acquaintance with PHC. In march 2022, an online series of eight lectures was organized to standardize the level of knowledge and increase awareness of this field. This study aimed to evaluate the impact of these lectures. More than 900 PH residents attended the

lessons. After the lectures, a questionnaire was administered. It consisted of 4 sections: general organization, speakers' competence, acquired knowledge and overall opinion. In each question participants had to indicate a score from 1 to 5 (likert scale) based on their satisfaction. Chi-square tests were performed to compare results from different groups. A total of 410 PH residents from each Italian region (north 51%, center 21%, south 28%) answered the questionnaire. 92% of participants assigned a high global score (≥ 4), 68% assigned a score ≥ 4 to the acquired knowledge. Residents in their iii or iv years of school, compared with those in their i or ii, considered the competencies acquired transferrable in their working context ($p=0.040$). Residents in their i and ii years were more interested in additional lessons ($p=0.041$). Overall opinion was not different between those who followed the lessons voluntarily or mandatorily ($p>0.05$). This series of conferences has increased perceived knowledge and awareness of PHC issues. These results suggest that it is possible to think of homogeneous and standardized training courses that PH residents can attend in synchrony from all over the country.

Students learn better when we design public health curricula using systems thinking principles

Simon Reid¹, Nicholas Osborne², Sheleigh Lawler³, Angela Willemsen⁴, Karen Shelley⁵

¹School of Public Health, The University of Queensland, Queensland,

²School of Public Health, The University of Queensland, Queensland,

Australia, ³School of Public Health, University of Queensland, Queensland,

Australia, ⁴School of Public Health, The University of Queensland, Herston

Road, Queensland, Australia, ⁵School of Public Health, The University of

Queensland, Queensland, Australia

Background and Objective: The complexity and uncertainty of the COVID-19 pandemic highlights the need to change training of public health professionals in higher education by shifting from siloed specialisations to interdisciplinary collaboration. At the end of 2020 and 2021, public health professionals collaboratively designed and delivered, a week-long intensive course—Public Health in Pandemics. The aim of this research study was to understand whether the use of systems thinking in the design and delivery of the course enabled students to grasp the interdisciplinary nature of contemporary health promotion and public health practice.

Methods: Two focus group interviews ($n = 5$ and $3/47$) and a course opinion survey ($n = 11/47$) were utilised to gather information from students regarding experiences and perceptions of course design and delivery, and to determine if students felt better able to understand the complex nature of pandemics and pandemic responses.

Results: Students provided positive feedback on the course and believed that the course design and delivery assisted in understanding the complex nature of health problems and the ways in which health promotion and public health practitioners need to work across sectors with diverse disciplines for pandemic responses.

Conclusions: The use of an integrated interdisciplinary approach to course design and delivery enabled students used systems thinking to understand the complexity in preparing for and responding to a pandemic. This approach may have utility in preparing an agile, iterative and adaptive health promotion and public health workforce more capable of facing the challenges and complexity in public health.

Investigating the international immigration tendency of intern doctors in Türkiye and related factors

Berna Sert¹, Ahmet Uzun², Süleyman Konuş¹, Coşkun Bakar¹, Gamze Çan¹

¹Public Health Department, Faculty of Medicine, Canakkale Onsekiz Mart

University, Türkiye, ²Canakkale Yenice State Hospital, Türkiye

Background and Objective: In the last decade, immigrating to developed countries has been a popular topic among young doctors in Türkiye. In the beginning of 2022, the Discussions about doctors' immigration were in the focus of national media. However, there was a clear lack of scientific data. This study aimed to investigate the tendencies of intern doctors towards international immigration, and to determine the factors that may induce a desire to immigrate.

Methods: 206 intern doctors that were reached through social media, participated in the study by filling the online form between March 1 - 21, 2022. The form included questions about descriptive features, Attitude Towards Brain Drain Scale(ATBDS) and the Beck Hopelessness Scale(BHS).

Results: 82.0% of participants were exposed to verbal violence while working, 6.3% were exposed to both verbal and physical violence. 85.9% wanted to work abroad,

74.5% of these participants made this decision during their clinical training. 64.6% of the participants were planning to take board exams abroad. Most of the participants wanted to take board exams of United Kingdom (64.6%), followed by United States (37.6%), Germany (15.8%) and Canada (12.78%). The mean of BHS scores was found to be 9,13(SD=4,31). ATBDS scores were found to be higher in the intern doctors who have been exposed to physical violence, who have a history of being abroad, who are currently taking or have plans to take a foreign language course, who want to work abroad, who have plans to take foreign residency exams and who do not plan to take residency entrance exam in Türkiye ($p<0.05$).

Recommendations: Brain drain tendencies may indicate an increase in the need of general practitioners and specialists. New researches should examine the push and pull factors that lead young doctors to migrate, and guide policymakers to solve the push factors.

Changes in cultural competency among emergency department staff in a large urban hospital following the implementation of an Indigenous Cultural Safety education program

Chenoa Cassidy-Matthews^{1,2}, Leslie Bonshor², Andreas Pilarinos^{1,2}, Sandra

Fox³, Lori Quinn³, Krisztina Vasarhelyi^{4,3}, Brittany Bingham^{1,5,2}

¹University of British Columbia, Canada, ²Vancouver Coastal Health, Canada,

³Vancouver Coastal Health Authority, Canada, ⁴Simon Fraser University,

Canada, ⁵Centre for Gender and Sexual Health Equity, Canada

Introduction: Anti-Indigenous racism within healthcare has been well-documented globally. In response, there have been calls for the expansion of Indigenous cultural safety (ICS) education to all healthcare staff. Given limited evidence on the impacts of ICS education within acute healthcare settings, this study sought to evaluate changes in Emergency Department (ED) staff's understanding and application of ICS within their health care practice. **Methods:** Employing a one-group, pre- and post-test study design, the Cultural Capability Measurement Tool (CCMT), and other standalone questions on cultural competence, were administered to ED staff at a large urban hospital in Vancouver, Canada both before and after the completion of a new, introductory, and in-person ICS education program. Paired t-tests examined changes in CCMT scores, and Wilcoxon rank sign test was used to assess changes in standalone questions.

Results: A total 66 ED staff complete a pre- and post-test survey. Statistically significant improvements were seen in three of four of the domains of the CCMT, including in respect ($p=0.015$), communication ($p<0.001$), and safety and quality ($p=0.005$), though no statistically significant improvements were observed in the reflection and advocacy domain ($p=0.189$). Similarly, statistically significant improvements were observed across other measures of cultural competency in relation to general knowledge, workplace applications of ICS, and how to meaningfully engage with Indigenous patients (all $p<0.05$). **Conclusions:** Findings indicate that expanding ICS education in healthcare is critical to reducing anti-Indigenous racism and improving Indigenous Peoples' trust in the healthcare system. This may include providing regular, routine ICS education opportunities for healthcare staff and incorporating ICS teachings into medical education curriculum. Future research comparing changes in cultural competency between an intervention and control group of healthcare staff is recommended and would be valuable, as well as research into Indigenous Peoples' experiences before and after the implementation of a healthcare-specific ICS education program.

Perceptions towards an e-learning approach Public Health students at a South African University

Kavitha Naicker¹

¹University of Pretoria, South Africa

Background and Objective: Technological advancements have been making its way into many aspects of our homes and livelihood. And our educational system is no exception to this technological advancement, since its Introduction into the system in the 1990's. This is in addition to meeting the demands of globalisation and the need for information accessibility and technological advancements. However, these advancements have shown to be not well received and perceived by students. And therefore, the objective of the current study is to determine the perceptions and experiences of e-learning amongst Postgraduate Public Health students in South Africa in order to optimise learning strategies whilst improving the learning environment for studying to be more enjoyable. This in turn would Results in a two-way benefit, in that more students would uptake e-learning studies, whilst higher educational institutions would run successful programs. The need for this study was highlighted by several research findings that suggest that there

are several perceptions of students towards e-learning that needs investigation. Methods: The sample will consist of two cohorts from the Postgraduate Diploma in Public Health at a South African University. All students in these cohorts will be provided with a link that provides information on the study, in addition to the Perceptions towards an e-learning approach Questionnaire.

Results and Conclusions: Preliminary results indicate that students in general experience e-learning as positive. They are a bit lost in the beginning, but eventually find their way in the learning journey. They struggle with time-management, workload management, balancing work, family and study life. They complain about instructions, and they procrastinate. Since data will still need to be collected, analysis might confirm, deny or add to these findings.

Piloting the Informed Health Choices resources in Barcelona primary schools: a mixed method study

Laura Jofra¹, Laura Jofra¹, Esther Martínez², Pablo Alonso-Coello², Sarah Rosenbaum³, Laura García²

¹Hospital de la Santa Creu i Sant Pau, Spain, ²Centro Cochrane Iberoamericano, Instituto de Investigación Biomédica Sant Pau (IIB-Sant Pau), Spain, ³Centre for Informed Health Choices, Norwegian Institute of Public Health, Norway

Introduction: The main Objective of the Informed Health Choices (IHC) project is to teach people to assess treatment claims and make informed health choices. For this purpose, the IHC learning resources were developed for primary school children. The aim of this study is to explore students' and teachers' experiences when using the IHC resources in Barcelona (Spain) primary schools.

Methods: We conducted a mixed method study for piloting the IHC resources in Barcelona (Spain) primary schools. The intervention included a workshop with teachers and family members, and nine lessons with the students. We collected data using multiple approaches, including ad hoc questionnaires, non-participatory observations, and semi-structured interviews. We performed quantitative and qualitative thematic analyses to explore understandability, desirability, suitability, usefulness, and facilitators and barriers for using the IHC resources.

Results: Two schools with a total of 143 students in 4th and 5th grade (9 to 11-year-olds) and six teachers participated in the study. One school completed all the lessons and followed the suggested IHC teaching plan. The other school did not complete all the lessons and changed the teaching plan substantially. Overall, students and teachers understood, were interested, and were able to apply the content of the lessons. During the lessons, students used the IHC resources (mainly the textbook), but teachers used them in a variable way. Teachers adapted the IHC resources to promote increased student participation and used Information and Communications Technologies to support their teaching. We observed more facilitators than barriers to teach the lessons. Teachers suggested some ideas to improve the lessons based on the activities they developed and implemented. Conclusions: It is feasible to use the IHC resources in Barcelona primary schools. However, the IHC resources should be adapted for this setting to increase students' participation in classroom.

DOI: 10.18332/popmed/165501

How do young women perceive and shape the culture of postsecondary education in rural Canada?

Alexa Ferdinands¹, Dana Wagner¹, Maria Mayan¹

¹University of Alberta, Canada

Background and Objective: Postsecondary educational attainment, one of the most compelling social determinants of health, is lower (45%) than the national average (65%) for women in Drayton Valley, a rural oil and gas town in Canada. Traditional gender roles are entrenched in Drayton Valley, including social norms surrounding education. Men are encouraged to enter well-paid oil field work straight from high school, making it possible to have one income-earner families where women can be at home with children. However, undertaking postsecondary education may help mitigate health consequences (e.g., increased stress, anxiety) for young women growing up in a unstable boom-and-bust economy. To shift social norms, deep understanding of the local culture of education is needed. In this study, conducted in partnership with the Town of Drayton Valley, we aim to explore how young women perceive and shape the culture of postsecondary education in their community.

Methods: We used focused ethnography to achieve this aim. Focused ethnography focuses on culture as it pertains to discrete social phenomena and contexts. Since July 2022, we have completed 16 individual interviews with young women living in Drayton Valley aged 16-19. Questions revolve around participants' experiences of

growing up in Drayton Valley, how they plan for their futures after high school, their hopes and dreams, and perceived barriers to and opportunities for postsecondary education. Qualitative content analysis is being used to analyze findings.

Results: Findings suggest that young women are challenging gender roles and stereotypes traditionally tied to notions of femininity in rural oil and gas communities. Analyses remain underway; final themes will be presented at the Congress. Conclusions: Findings may be relevant for other rural communities around the world interested in shifting social norms, including those tied to gender, around postsecondary education, as a means of improving young women's health and social outcomes.

Popul. Med. 2023;5(Supplement):A681

DOI: 10.18332/popmed/165515

Examining the development, implementation, and sustainability of a tuition assistance program in a rural Canadian community

Maria Mayan¹, Alexa Ferdinands¹, Tina Watchman¹, Matt Ormandy¹, Dana Wagner¹, Brooks Hanewich¹

¹University of Alberta, Canada

Background and Objective: Rural, oil and gas towns in Canada face several challenges (e.g., boom-and-bust cycles, low educational attainment rates) that adversely affect economic stability, and consequently, residents' physical, mental, and social health. In response to these challenges, one such town, Drayton Valley, introduced a tuition assistance program (up to \$5000 CAD per resident) in 2019 to reduce financial barriers to select postsecondary education and training programs. While the program offers opportunities to train in fields independent of oil and gas, it also may retain residents and attract new people to the town. In partnership with the Town of Drayton Valley, along with evidence that education is one of the most important determinants of health, we aimed to examine the facilitators of and barriers to developing, implementing, and sustaining this program.

Methods: This qualitative study was underpinned by principles of community-based participatory research. Between August 2021 and June 2022, we conducted 11 interviews with stakeholders (elected officials, local administration, postsecondary institution representatives) and participated in 5 group stakeholder consultations, facilitated by a community economic development consultant. Interview transcripts and fieldnotes were analyzed using qualitative content analysis.

Results: We developed five categories which speak to the facilitators and barriers of developing, implementing, and sustaining Drayton Valley's tuition assistance program: 1) lack of a unified vision and goals; 2) unique context of postsecondary education and training in Drayton Valley; 3) innovative champions of education; 4) stakeholder collaborations and multisectoral partnerships; and 5) establishing community buy-in. In this presentation, we will summarize recommendations for capitalizing on facilitators and addressing barriers as the town moves forward with this program.

Conclusions: This study contributes to the limited knowledge on tuition assistance programs in Canada. Findings may have implications for other rural communities interested in using tuition assistance programs as innovative tools for promoting health equity.

Popul. Med. 2023;5(Supplement):A682

DOI: 10.18332/popmed/165517

Developing a framework for collaborative education and training of the next generation of global health professionals: experiences and challenges

Iman Hakim¹, Gabriella Valdez¹, Roxanna Apaez²

¹Mel and Enid Zuckerman College of Public Health, University of Arizona, Tucson, United States, ²Mel and Enid Zuckerman College of Public Health, University of Arizona, Tucson, United States

Background and Objectives: There is a tremendous need for a global health workforce that is competent to deal with emerging global health issues. Global health education and training provide unique collaborative opportunities to address the global burden of disease by training the next generation of global health experts. The Mel and Enid Zuckerman College of Public Health (MEZCOPH) at the University of Arizona is an example of an institution that has recently invested in global health infrastructure and academic programs. MEZCOPH established the Global Health Institute (GHI) to provide innovative and transformative public health education, scholarship, research, advocacy, and leadership training for health care professionals worldwide.

Methods: The rapidly evolving convergence of the physical, digital and biological fields is reshaping and transforming higher education. This Fourth Industrial Revolution will lead to the continuous Introduction of new technologies which will mandate new and innovative ways of experiential learning. The new and emerging

digital media technologies provide feasible and cost-effective alternatives to traditional classroom instruction.

Results: The GHI implemented an innovative approach to internationalization by establishing a worldwide network of global partners and/or micro-campuses to deliver collaborative educational and training programs including unique dual degree programs overseas to local students and different summer and global engagement programs. These programs rely on the full collaboration between GHI and its worldwide partners. I will discuss our micro-campus experience and other GHI ongoing programs with our network of global partners. I will highlight the successes, challenges, and lessons learned

Conclusions: Collaborations in global health education and training, while tremendously advantageous, can be demanding and challenging.

Are students and teachers of Slovak medical university motivated for physical activity?

Katarina Dostalova¹, Eva Palugova¹, Peter Simko¹, Sona Wimmerova¹, Eva Horvathova¹, Stefania Moricova¹

¹Slovak Medical University, Bratislava, Slovak Republic

The importance of physical activity (PA) for the human body is very well known. The physical inactivity significantly contributes to the development of chronic diseases and premature mortality. The Slovak Medical University (SMU) in Bratislava is a higher education institution keeping the tradition of education of health care workers in specialised studies and continuous lifelong education in Slovakia. It is assumed that students and teachers of SMU with mission to educate for prevention and a healthy lifestyle, follow the principles of a healthy lifestyle in their personal lives. According to WHO adults aged 18–64 years should do at least 150–300 minutes of moderate-intensity aerobic PA.

Methods: We analyzed and compared the physical activity of teachers and students of SMU. The group consisted of 101 teachers and 242 students. Data collection was performed through an anonymous electronic questionnaire.

Results: 44 teachers (43.56%) and 60 students (24.79%) engage in PA for more than 150 minutes per week. We analyzed the motivation of respondents to PA. 144 respondents are motivated to perform PA by friends (18.81% of teachers and 51.65% of students). 137 respondents chose the family as the main motivation (66.34% of teachers and 28.93% of students). Social networks, the internet, television and advertising motivate only 3 students (1.24%).

Conclusions: It is astonishing that only a quarter of SMU students meet the WHO recommendations for PA. It is a challenge for SMU teachers to pass on to their students' knowledge about a healthy lifestyle not only in theoretical form, but also their personal experiences from everyday life. We explain the low share of motivation through social networks and the internet to PA and, on the contrary, motivation mainly by close people (family in teachers and friends in students) in the current pandemic situation, when personal contact becomes highly valued.

Defining the elements of a regional accreditation system for academic institutions of public health in Africa: methodological processes

Neo Ledibane¹, Liz Wolvaardt¹, Kuku Voyi¹

¹School of Health Systems and Public Health, Faculty of Health Sciences, University of Pretoria, Pretoria, South Africa

Background: Health systems in Africa require an overhaul to align with the universal health coverage (UHC) mandate and a parallel review of public health training and development of the health workforce is warranted. One of the integral components that inform the relevance of public health education in the setting of UHC is the capacities of the academic institutions of public health. The aims of the study are to define the elements that comprise the public health education capacity within academic institutions and to develop an accreditation system for the African region. Methods: Study design: quantitative analytical cross-sectional design with a qualitative component. Study setting: ASPHA (Association of Schools of Public Health in Africa)-affiliated academic institutions of public health at Anglophone, Lusophone, Francophone countries in Africa. Study population: Heads/Deans of Departments/Schools of Public Health. Phase 1: A secure, electronic self-administered questionnaire measuring the institutional baseline characteristics (academics' demographic, curriculum and institution characteristics) underwent five iterations, was piloted and translated into French and Portuguese. The survey launched in November 2022. Quantitative data analysis will be performed using STATA version 17; thematic analysis will be applied to the qualitative data using the ATLAS.ti software.

Results: The preliminary Results will be presented at the conference. These results will form the basis of the elements of a Delphi panel in Phase 2 of the study. The planned outcome of Phase 2 is a self- and peer-assessment tool that can be tested (in Phase 3) as a first step towards accreditation. Conclusions: The study findings are envisaged to inform the development of an accreditation system for the association so that the academic institutions of public health can align their workforce training and development to the changing health and health system needs of Africa.

Current problems in nursing and midwifery research in Bulgaria (2020-2022)

Milena Saleva^{1,2}, Gena Grancharova², Silviya Yankulovska^{2,1}, Makreta Draganova^{2,1}

¹Faculty of Public Health, Medical University of Pleven, Pleven, Bulgaria,

²Bulgarian Public Health Association, Bulgaria

Background and Objectives: The research in nursing and midwifery in developed countries has a long tradition and is very well positioned. In Bulgaria, this activity is promoted during the last decades with the introduction of Bachelor degree in basic training of nurses and midwives and Master degree for educators and managerial positions in health care. We aimed to reveal the main problems hindering the development of research in Bulgarian nursing and midwifery. Methods: A total of 1097 anonymous self-administered questionnaires (with closed, semi-closed and open questions) were distributed among practicing nurses and midwives in 8 hospitals and educators and fourth-year students in 6 higher schools. The response rate was 78.9%; higher for students (85.2%), followed by 79.3% for practitioners and 77.2% for educators. Data processing was performed by SPSS v.24 using descriptive statistics and comparative analysis. The accepted level of significance was $p < 0.05$.

Results: All the respondents pointed out the lack of time due to insufficient staffing. The situation was exacerbated by COVID-19 pandemic. Lack of motivation and underestimation of the efforts by the employers was the second factor for 36.6% of practitioners and ranked as third by 57.5% of educators and 58.9% of students ($P < 0.01$). The lack of funding was indicated by 30.4% of practitioners and 28.3% of students. Insufficient knowledge and skills for conducting research were recognised as other important problems together with poor command in foreign language and lack of standardized documentation in healthcare practice. Good computer skills and knowledge were not among the main problems. Conclusions: When studying the current situation of research, it is important to look for the problems that hinder its development. The results of our study serve as important signals for concrete actions to be taken to overcome the problems and to encourage research among nurses and midwives.

Popul. Med. 2023;5(Supplement):A686

DOI: 10.18332/popmed/165624

Implementation of a comprehensive approach to health promotion at the school and community levels: preliminary findings from the Alliance for Health project

Axelle Giron¹, Marine Genton², Carine Simar³, Véronique Denois⁴, Julie Pironom³, Julien Masson⁵, Didier Jourdan⁶, Franck Chauvin⁷

¹University Jean Monnet Saint-Etienne, France, ²University Jean Monnet Saint-Etienne, Saint-Priest-en-Jarez, France, ³University Clermont-Auvergne, UR4281 ACTé, Chamalières, France, ⁴University Jean Monnet Saint-Etienne, UR4129 P2S, France, ⁵University Claude Bernard Lyon 1, UR 4129 P2S, ⁶University Clermont-Auvergne, Chamalières, France, ⁷University Jean Monnet Saint-Etienne, France

Background and Objective: Supporting children in developing health skills goes, according to research, through a comprehensive approach to health promotion. The Alliance for health project aims to enact and assess the impact of a comprehensive approach to health promotion at the school and community levels. This intersectoral project involves regional education authorities, regional public health agency, local policy makers, researchers, and local health promotion operators.

Methods: This project involved 48 French primary schools and 47 associated municipalities in the AURA region randomly selected. From September 2019 to June 2022, the intervention was implemented. Primary school teachers were provided training, support, and resources to develop a health-promoting environment in school according to the Health-Promoting Schools framework. Meanwhile, school deputies and territorial agents involved in extracurricular activities were provided training, support, and resources in the same aim. Intersectoral working sessions were promoted. To analyze implementation outcomes, semi-structured interviews

were conducted in Spring 2022.

Results: This qualitative study included 11 district pedagogical advisors, 10 school principals, 9 school deputies, 2 extracurricular agents, 1 person in charge of after-school programs and 1 health promotion project manager. Schools' perspective. Identified facilitators were a constant and available referral, institutional support and dedicated time, clear aim and issues from the beginning, community support, multi-school training sessions, contextualized support. Barriers were COVID-pandemic, lack of community support, lack of time. Community perspective. Identified facilitators were health promotion perceived legitimacy, collective motivation, regular and effective working sessions. Barriers were perceived methodological incompetence, administrative burden, lack of time.

Conclusions: Collective work dynamics, practices' exchanges, health promotion professional identity are essential implementation components. Lack of time is perceived as a structural barrier. Communities pointed out perceived legitimacy and competences as corner-stones of their engagement.

Popul. Med. 2023;5(Supplement):A687

The necessity of research skills training for nurses and midwives in Bulgaria

Milena Saleva^{1,2}, Silviya Aleksandrova-Yankulovska^{3,1}, Makreta Draganova^{3,1}, Gena Grancharova³

¹Medical University of Pleven, Pleven, Bulgaria, ²Bulgarian Association of Public Health, Pleven, Bulgaria, ³Bulgarian Association of Public Health, Bulgaria

Background and Objective: The recommendations of international organizations require to start training for research in health care from the basic training. In Bulgaria, the Ordinance on the Unified State Requirements for the acquisition of Bachelor degree in Nursing and Midwifery and Master degree in Management of Health Care (2006) do not include mandatory disciplines for acquiring specific knowledge and skills for research. The aim of the study was to find out how nurses and midwives evaluate their research preparation and their basic needs.

Methods: Within a more complex study on research in nursing and midwifery, practitioners in 8 hospitals, educators and fourth-year students in 6 universities were surveyed through an anonymous self-administered questionnaire. Out of a total of 1 097 distributed questionnaires, 78.9% responded, with the highest rate among students (85.2%), followed by practitioners (79.3%) and educators (77.2). Data processing was performed by SPSS v.24 using descriptive statistics and comparative analysis. The accepted level of significance was $p < 0.05$.

Results: Statistically significant differences were found in all three groups regarding their self-assessment of confidence to undertake specific research activities ($P < 0.05$). The proportion of practitioners who definitely do not feel prepared for research was 38.9%. Among the trainees, there was a slight predominance of those who feel confident (57.8%). The highest proportion of confidence in their preparation for research was among educators (62.0%) for which research is an obligatory element of their position. In all three groups, the largest proportion of persons supported the opinion that the acquisition of basic competencies for research should start in basic education and should be upgraded during the Bachelor and Master programs in the specialty "Health Care Management".

Conclusions: There is a necessity to introduce research training into basic nursing and midwifery education, justified by regulatory requirements and their poor assessment of research skills.

Popul. Med. 2023;5(Supplement):A688

DOI: 10.18332/popmed/165647

Health care professionals' knowledge on chronic noncancer pain in pediatric age

Paula Oliveira¹, Clara Abadeso², Humberto Machado³, José Romão³

¹Public Health Unit of Porto Ocidental, Portugal, ²Pediatric Department, Prof. Dr Fernando Fonseca Hospital, Portugal, ³School of Medicine and Biomedical Sciences, University of Porto, Portugal

Background and Objectives: The health care professionals' knowledge on chronic noncancer pain in pediatric age may have implications in clinical practice, and eventually impact on patients' health-related quality of life. However, there are no research studies in Portugal addressing that issue. Our main goals were to study health care professionals' knowledge on chronic noncancer pain in pediatric age, as well as associated variables, namely sociodemographic and professional variables, perception of knowledge, and behavioral attitudes regarding chronic noncancer pain in pediatric age. A self-report questionnaire was developed to evaluate the variables under study.

Methods: 66 doctors and 71 nurses (N = 137) practicing with pediatric patients completed a self-report questionnaire in order to evaluate: knowledge on chronic

noncancer pain ("definition/epidemiology/pathophysiology"; "psychosocial aspects"; "pain assessment"; "pharmacological treatment" and "non-pharmacological treatment"), sociodemographic and professional variables, perception of knowledge, and behavioral attitudes regarding chronic noncancer pain in pediatric age.

Results: The overall level of health professionals' knowledge on chronic noncancer pain at pediatric age is moderate (M = 65.69; SD = 11.01) [0-100]. The highest scores were in "psychosocial aspects" and "non-pharmacological treatment" subscales; the lowest scores were in "pharmacological treatment" and "definition/epidemiology/pathophysiology" subscales. In addition, our results showed that the overall level of knowledge is related to the perception of knowledge (namely, awareness of pediatric pain assessment national guidelines, and perceived ability to apply pain rating scales in pediatric age), as well as behavioral attitudes (namely systematic pain assessment and recording at an appointment with a pediatric patient, as well as performing etiological assessment in the medical approach of patients with chronic noncancer pain).

Conclusions: Our data support the relevance of developing training programs focused on promoting health care professionals' knowledge on chronic noncancer pain in pediatric age, pointing out areas in which such programs should be focused.

DOI: 10.18332/popmed/165648

Pre-service teachers' experiences with students impacted by Trauma in the school setting

Ella Carton^{1,2}, Karen Martin³, Alix Woolard⁴, Kate Fitzgerald²

¹Telethon Kids Institute, Australia, ²The University of Western Australia, Australia, ³The University of Tasmania, Australia, ⁴Telethon Kids Institut, The University of Western Australia, Australia

Background: Experiencing trauma can adversely impact a child's education and their lifelong social, physical and mental health. Trauma is poorly understood by those working within the education sector. Teachers play a pivotal role in recognising and helping when children display trauma-related behaviours, but risk re-traumatising children if not adequately trained. Pre-service teachers (PSTs) have limited exposure and experience in responding to the different needs experienced by children impacted by trauma. This research explored PST education and training about trauma and its impact, and their knowledge and experience in supporting children whilst on practicums.

Methods: Phenomenological analysis of in-depth interviews with 15 undergraduate PSTs attending three Western Australian universities explored their knowledge and experiences in working with children impacted by trauma.

Results: Themes emerging from the data included; PSTs' teaching preparedness, experiences and emotions on practicums, support during and after practicums and recommendations. Participants received almost no education or training about how to support children impacted by trauma, felt underprepared, lacked support from schools and their university, and noted issues with inadequate trauma-informed practices in some classrooms. A prominent finding resonating with all participants was the importance of gaining an understanding about trauma to better equip PSTs with the knowledge and confidence to support children.

Conclusions: This research suggests PSTs may not be receiving sufficient training at university about how to support children impacted by trauma and feel underprepared on practicums. Results highlight the importance of teacher education and training in preparing future teachers about supporting children impacted by trauma. The results demonstrate the necessity for conceptual changes around university education and support for PSTs in classrooms. These results are relevant internationally for education sectors in ensuring adequate training of our future teachers, universities in their teaching courses and for schools in how best to support their practicum and school students.

DOI: 10.18332/popmed/165667

One Health, Multiple backgrounds

Giorgia Soldà¹, Giorgia Soldà¹, Angelo Capodici¹, Marco Montalti¹, Aurelia Salussolia¹, Zeno Valerio¹, Giusy Fauci¹, Francesca Scognamiglio¹

¹University of Bologna, Italy

Background and Objective: One Health (OH) is considered to be a trans-disciplinary topic. In 2010, Fao, Woah, and who recognized that to address health risks, strong partnerships among players with different perspectives are required. However, in Italy, oh is only taught in a few university courses and is excluded from medicine and surgery. In October 2021, as first-year Public Health (PH) residents of the university of bologna, we decided to organize a winter school on oh open to medical residents, veterinarians, nurses, and biologists' students.

Methods: The course lasted 4 days dedicated to human, environmental, and

animal health. It was recognized from the beginning the core importance of having an interprofessional environment, both for the lecturers and the trainees. In particular, morning activities were led by experts of multiple backgrounds, such as PH, veterinary, chemistry, geology, agriculture, statistics, environmental engineering, health economics, psychiatry, endocrinology, and microbiology, while the afternoons by the PH residents who integrated the morning topics with soft skills such as leadership and advocacy.

Results: Frontal lessons covered different fields of expertise, and known and neglected problems and highlighted the gap between real-world issues and the academic division of knowledge. The involvement of PH residents was instrumental in implementing a peer-to-peer learning approach, involving participants in debates and encouraging them to express ideas and insights on specific issues to view them in a multi-disciplinary framework.

Conclusions: Every participant was asked to fill out an evaluation form at the end of each day. Soft-skills training sessions were widely appreciated and participants acknowledged the course's added value of facilitating the intersection between different fields of knowledge. Traditional educational approaches often underestimate the importance of a transdisciplinary approach, even though it appears fundamental in order to effectively assess real-world problems, and professionals are deeply aware of this gap in their education.

Study on the satisfaction of medical students with distance learning during the period of COVID-19 restrictions for the perspective of the Karaganda Medical University, Kazakhstan

Zhaniya Dauletkaliyeva¹, Karina Nukeshtayeva¹

¹Karaganda Medical University, Kazakhstan

Background and Objectives: The current situation associated with the pandemic has led to transitional distance learning methods in higher education. The aim of the study is to determine the attitude of students towards distance learning at a medical university and to identify the problems they faced.

Methods: The design of the study is cross-sectional. An electronic questionnaire was assigned, and 1238 students were interviewed. The study was conducted after replacing traditional face-to-face education.

Results: 38.2% of students have perfectly adapted to distance learning. At the same time, 3.1% adapted to online learning poorly. 67.1% of respondents report that they were absolutely comfortable learning online, and only 6.6% of respondents report that it was very difficult. 40.5% of respondents believe that their workload has increased during the period of delayed learning, and slightly fewer respondents report that the workload has not changed. The majority of students rate the work of the teaching staff during distance learning as "excellent", however, still, 3% of students rate the work of the teacher as "bad". The main requirements that students have faced during the long period of study are the technical conditions, the poor performance of the Internet in the regions where the students are located during the distance learning period. In general, 48.1% of students are completely satisfied with the learning process during distance learning, while 4.6% of students are completely satisfied. It is noted that students of lower grades have an increased frequency of increased values of the training load during long-term training (p-value < 0.001).

Conclusions: Much attention is paid to solving the problem of digital literacy among the teaching staff and students, as well as increasing the availability of digital technologies for all students, regardless of their distance from the university.

health and Infectious Diseases, Italy, ⁴University of Padua, Department of Information Engineering, Italy

Background and Objective: In the last decades, several educational strategies have been identified to improve the skills of students and promote deep learning. The use of virtual reality (VR), immersive (IR) or augmented reality (AR) and metaverse (MV) technologies can be engaging and interactive learning resources and easily updated in line with the learning needs. While digital education is increasingly used in teaching, it is not very clear how effective. To address this gap a systematic review has been conducted to investigate the academic

performance, satisfaction, and acceptability of this digital education in university students of medicine.

Methods: The review was conducted according to the guidelines of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses. The following databases were searched from their earliest records until October 30th, 2022: PubMed, Scopus (Elsevier), and Web of Science. The following search string was applied: (metaverse OR "immersive reality" OR "virtual reality" OR "augmented reality") AND ("Medical Students" OR "Medical Training" OR Triability OR Teaching) AND University AND (satisfaction OR Acceptance OR Performance). Only studies focused on undergraduate students of medicine/dentistry/degree courses in the health professions were considered. Only experimental studies were included.

Results: Actually, the systematic review is in progress. The preliminary results of the search through the scientific literature identified 372 citations. 32 studies were selected: 4 full texts are not available, 17 RCT, 10 quasi-experimental trials, and 1 quasi-randomized trial. Considering only the studies that measured academic performance (N=26), 13 of them indicated significantly superior performance with the equipment for the VR or analog technologies trained students.

Conclusion: VR simulation was at least as effective as traditional learning methods in training medical students while providing benefits regarding user satisfaction. VR is useful for learning both simple and complex clinical skills, according to these findings.

Climate crisis and planetary health in Italian medical schools' curricula: a scoping review

Doris Zjalic¹, Gaia Lombardi¹, Giulia Congedo¹, Doris Zjalic¹, Alessio Perilli¹, Mattia Di Russo¹, Chiara Cadeddu¹

¹Università Cattolica del Sacro Cuore, Italian Institute for Planetary Health, Italy

Background and Objective: Italy is considered a hotspot for climate change in the Mediterranean region and people living in it are already affected by environmental modifications. Medical doctors have a key role in tackling with the consequences of this threat by providing direct care and correct education, preparing the population, helping in adaptation process, and advocating for public health policies. To achieve this aim, medical doctors need solid knowledge about the interconnection between human health and climate crisis, which is a cornerstone of Planetary Health. The aim of this study is to analyse whether Italian medicine schools' curricula incorporate Planetary Health and climate change topics.

Methods: A review of all medicine degree courses in Italy was conducted in December 2022 on academic websites of each course founded on the "UniversItaly.it" institutional portal. In each programme, we searched for the Italian terms for "climate change", "environmental change", "planetary health", "one health" and we synthesized the results in a database, which was used to set out the Italian situation with descriptive statistics.

Results: Forty-eight medical schools and eighty-three degree courses have been included. Preliminary data show that only 4 schools out of 48 (8.3%) offer elective courses on the subject and in 13 courses out of 83 (10.8%) there is a teaching course that includes Planetary Health topics in the programme.

Conclusion: This review shows that Italian future medical doctors are receiving an insufficient education in their degree courses on climate crisis and environmental matters, which comprise 25% of the global burden of disease. Medical doctors need to be aware of global environmental changes and to be actively involved in population health protection and support for policymaking. Planetary Health Educational framework shows the way to reach this goal, developing knowledge and skills to face the problem.

Impact of an infection prevention and control intervention on the management of a mdro outbreak in a medical department

Matteo Rigoni¹, Chiara Dalle Carbonare², Sofia Zanollo², Davide Brodesco², Maria Zanon², Francesco De Siena¹, Vinicio Manfrin³, Mario Rassu⁴, Sara Mondino², Romina Cazzaro²

¹University of Padua, Dept. of Cardiac, Thoracic, Vascular Sciences and Public Health, Italy, ²AULSS 8 Berica, Hospital Direction, Italy, ³AULSS 8 Berica, Infectious Disease Department, Italy, ⁴AULSS 8 Berica, Microbiology and Virology Department, Italy

Background and Objective: In November 2021 there was a steady increase of Multidrug-Resistant Microorganisms (MDRO) colonized patients in a medical department of san bortolo hospital (Vicenza, Italy): 6 Vancomycin-Resistant Enterococcus (VRE), 1 pseudomonas aeruginosa MDR. MDRO active surveillance

with rectal swabs was already performed to patients at admission and every 7 days (patients with known MDRO excluded). Therefore, targeted interventions were planned.

Methods: The implementation of an infection Prevention and Control (IPC) intervention was planned by the Infection Control Team (ICT) in order to analyze, contain and manage the phenomenon. Measures implemented by ICT with staff ward included a hand hygiene observation session, onsite training meetings with healthcare staff, environmental screening by performing swabs in colonized patients' rooms, analysis and revision of sanitizing protocols for electro-medical equipment and flusher disinfectors.

Results: The 3 inspections carried on revealed some critical issues, in particular: poor hand hygiene adherence, double gloves use, unclear dirty/clean pathways, uncorrect Personal Protective Equipment (PPE) removal sequence, presence of too much equipment in isolation rooms. Environmental swabs showed vire contamination on 1 bedside, 1 monitor, and 1 colonized patient garrison. The 3 onsite training meetings allowed the engagement of staff with focus on: proper hand hygiene, principles of antibiotic resistance, standard and contact precautions, proper use of PPE.

Conclusions: The IPC intervention allowed an improvement in the equipment arrangement in colonized patients rooms, a review of sanitization protocols and an improvement in PPE use procedures; staff engagement led to an increase in responsibility and knowledge, allowing the cluster to be contained and resolved within a month.

School based HIV education affecting girls in selected countries in Sub Saharan Africa

Ivainesu Musa¹

¹Thammasat University, Thailand

Introduction: There is a high level of hiv amongst adolescent girls and young women in sub saharan africa and this has affected progress towards achieving the 90-90-90 targets. The current strategies arent sufficient to make the goals; there is a need to revamp at different levels and one of these levels is education. The objectives of this were to review and describe school-based HIV education programmes involving girls. As well as to categorize and synthesize the key features of school-based programs, how they address known barriers to participation and how they incorporate important principles and guidelines.
